The object of the player is to score the points of the game by striking his ball through each of the hoops and against each of the pegs in a fixed order; and the side wins which first succeeds in scoring all the points with both the balls of the side. A metal clip corresponding in colour with the player’s ball is attached to the hoop or peg which that ball has next to make in the proper order, as a record of its progress in the game. No point is scored by passing through a hoop or hitting a peg except in the proper order. Thus, if a player has in any turn or turns driven his ball successively through hoops 1, 2, and 3, his clip is attached to hoop 4, and the next point to be made by him will be that hoop; and so on till all the points (hoops and pegs) have been scored. Each player starts in turn from any point in a “basilk” or area 3 ft. wide along the left-hand half of the “southern” boundary, marked A on the diagram, of the lawn—till 1906, from a point 1 ft. in front of the middle of hoop 1. If he fails either to make a point or to “roquet” (i.e., drive his ball against) another ball in play, his turn is at an end and the next player in order takes his turn in like manner. If he succeeds in scoring a point, he is entitled (as in billiards) to a stroke; he may then either attempt to score another point, or he may roquet a ball. Having roqueted a ball—provided he has not already roqueted the same ball in the same turn without having scored a point in the interval—he is entitled to two further strokes: first he must “take croquet,” i.e., he places his own ball (which from the moment of the roquet is “dead” or “in hand”) in contact with the roqueted ball on any side of it, and then strikes his own ball with his mallet, being bound to move or shake both balls perceptibly. If at the beginning of a turn the striker’s ball is in contact with another ball, a “roquet” is held to have been made and “croquet” must be taken at once. After taking croquet the striker is entitled to another stroke, with which he may score another point, or roquet another ball not previously roqueted in the same turn since a point was scored, or he may roquet in the same turn. Thus, by skillful alternation of scoring points and roqueting balls, a “break” may be made in which point after point, and even all the points in the game (for the ball in play), may be scored in a single turn, in addition to 3 or 4 points for the partner ball. The chief skill in the game perhaps consists in playing the stroke called “taking croquet” (but see below on the “rush”). Expert players can drive both balls together from one end of the ground to the other, or send one to a distance while retaining the other, or place each with accuracy in different directions as desired, the player obtaining position for scoring a point or roqueting another ball according to the strategical requirements of his position. Care has, however, to be taken in playing the croquet-stroke that both balls are absolutely moved or perceptibly shaken, and that neither of them be driven over the boundary line, for in either event the player’s next stroke is forfeited and his turn brought summarily to an end.

There are three distinct methods of holding the mallet among good players. A comparatively small number still adhere to the once universal “side stroke,” in which the player faces more or less at right angles to the line of aim, and strikes the ball very much like a golf-swing with his hands closed on the mallet shaft. The majority use “front play,” in which the player faces in the direction in which he proposes to send the ball. The essential characteristic of this stroke is that eye, hand and ball should be in the same vertical plane, and the stroke is rather a swing—the “pendulum stroke”—than a hit. There are two ways of playing it. The majority of right-handed front players swing the mallet outside the right foot, holding it with the left hand as a pivot at the top of the shaft, while the right hand (about 1½ in. lower down) applies the necessary force, though it must always be borne in mind that the heavy mallet-head, weighing from 3 to $\frac{3}{4}$ lb or even more, does the work by itself, and the nearer the stroke is to a simple swing, like that of a pendulum, the more likely it is to be accurate. Either the right or the left foot may be in advance, and should be roughly parallel to the line of aim, the player’s weight being mainly on the rear foot. Most of the best Irish and some English players swing the mallet between their feet, using a grip like that of the side player or golfer, with the hands close together, and often interlocking. It is claimed that the loss of power caused by the hampered swing—usually compensated by an extra heavy mallet—is more than counterbalanced by the greater accuracy in aim. The beginner is well advised to try all these methods, and adopt that which comes most natural to him. Skirted players, of course, are unable to use the Irish stroke; and, as

1The words “roquet” and “croquet” are pronounced as in French, with the mute.
CROQUET

one of the most meritorious features of croquet is that it is the only out-of-door game in which men and women can compete on terms of real equality, this has been put forward as a reason for barring it, if it is actually an advantage.

When a croquet ground is thoroughly smooth and level, the game gives scope for considerable skill; a great variety of strokes may be performed with the mallet, each having its own well-defined effect on the behaviour of the balls, while a knowledge of angles is essential. Skilful tactics are at least as necessary as skilful execution to enable the player so to dispose the balls on the ground while making a break that they may most effectively assist him in scoring his points. The tactics of croquet are in this respect similar to those of billiards, that the player tries to make what progress he can during his own break, and to leave the balls “safe” at the end of it; he must also keep in mind the needs of the other ball of his side by leaving his own ball, or the last player’s ball, or both, within easy roquetting distance or in useful positions, and that of the next player isolated. Good judgment is really more valuable than mechanical skill. Croquet is a game of combination, partners endeavouring to keep together for mutual help, and to keep their opponents apart. It is important always to leave the next player in such a position that he will be unable to score a point or roquet a ball; a break, however profitable, which does not end by doing this is often fatal. Formerly this might be done by leaving the next player’s ball in such a position that either a hoop or a peg lay between it and all the other balls (“wiring”), or so near to a hoop or peg that there was no room for a proper stroke to be taken in the required direction. Under rule 36 of the Laws of Croquet for 1906, a ball left in such a position, provided it were within a yard of the obstacle (“close-wired”), might at the striker’s option be moved one yard in any direction. This rule left to the striker whose ball was “wired” more than a yard from the hoop or peg (“distance-wired”) the possibility of hitting his ball in such a way as to jump the obstacle. The jump-shot is, however, very bad for the lawn, and in 1907 a further provision was made by which the player whose ball was left “wired” from all the other balls by the stroke of an opponent may lift it away from the “baulk” area. This practically means that “wiring” is impossible. The most that can be done is to “close-wire” the next player from two balls and leave him with a difficult shot at the third. If, however, the next player’s ball has not been moved by the adversary, the adversary is entitled to wire the balls as best he can.

The following is a specimen of elementary croquet tactics. If a player is going up to hoop 5 (diagram 1) in the course of a break, he should have contrived, if possible, to have a ball waiting for him at that hoop and another at hoop 6. With the aid of the first he runs hoop 5 and sends it on to the turning peg, stopping his ball in taking croquet close to the ball at 6. The corner hoops are the difficult ones, and after running hoop 6 the assisting ball is croqueted to 1 back, the peg being struck with the aid of the ball already there, which is again struck and driven to 2 back. If the player has been able to leave the fourth ball in the centre of the ground (known as a centre ball), he hits this after taking croquet, takes croquet, going off to the ball at 3 back, and continues the break, leaving the centre ball where it will be useful for 3 back and 4 back. A first-class player should, however, be able to make a break with 3 balls almost as easily as with 4. A useful device, especially in losing games, is to get rid of the opponent’s advanced ball if a “rover” (i.e. one which has run all the hoops and is for the winning peg) by croqueting it in such a way that it hits the peg and is thus out of the game. This can be done only by a ball which is itself also a rover. The opponent has then only one turn out of every three, and may be rendered practically helpless by leaving him always in a “safe” position. Inasmuch as a skilful player can cause an opponent’s ball to pass through the last two or even three hoops in the course of his turn and then peg it out, it is considered prudent to leave unrun the last three hoops until the partner’s ball is well advanced. There is a perennial agitation in the croquet world for a law prohibiting the player from pegging out his opponent’s ball. Many good players also think it desirable that the four-ball break should be restricted or wholly forbidden, e.g., by barring a player from playing a ball.

To “rush” a ball is to roquet it hard so that it proceeds for a considerable distance in a desired direction. This stroke requires absolute accuracy and often considerable force, which must be applied in such a way as to drive the player’s ball evenly; otherwise it is very liable, especially if the ground be not perfectly smooth, to jump the object ball. The rush stroke is absolutely essential to good play, as it enables croquet to be taken (e.g.) close to the required hoop, whereas to croquet into position from a great distance and also provide a ball for use after running the hoop is extremely difficult, often impossible. To “rush” successfully, the striker’s ball must lie near the object ball, preferably, though not necessarily, in the line of the rush. By means of the rush it is possible to accomplish the complete round with the assistance of one ball only. To “cut” a ball is to hit it on the edge and cause it to move at some desired angle. “Rolling croquet” is made either by hitting near the top of the player’s ball which gives it “follow,” or by making the mallet so hit the ball as to keep up a sustained pressure. The first however, result in a distinctly audible single tap; if a prolonged rattle is heard the stroke is foul. The passing stroke is merely an extension of this. Here the player’s ball proceeds a greater distance than the croqueted ball, but in somewhat the same direction. The “stop stroke” is made by a short, sharp tap, the mallet being withdrawn immediately after contact; the player’s ball only rolls a short distance, the other going much farther. The “jump stroke” is made by striking downwards on to the ball, which can thus be made to jump over another ball, or even a hoop. “Peeling” (a term derived from Walter H. Peel, a famous advocate of the policy) is the term applied to the device of putting a partner’s or an opponent’s ball through the hoops with a view to ultimately pegging it out.

The laws of croquet, and even the arrangement of the hoops, have not attained complete uniformity wherever the game is played. Croquet grounds are not always of full size, and some degree of elasticity in the rules is perhaps necessary to meet local conditions. The laws by which matches for the championship of small tournaments are governed are issued annually by the Croquet Association; and though from time to time trifling amendments may be made, they have probably reached permanence in essentials.

See The Encyclopaedia of Sport: The Complete Croquet Player (London, 1896); the latest Laws of Croquet, published annually by the Croquet Association, and its official organ The Croquet Gazette. For the principles of the game and its history in England, see C. D. Locock, Modern Croquet Tactics (London, 1907); A. Lilley, Croquet up to Date (London, 1900).

Croquet in the United States: Roque.—Croquet was brought to America from England soon after its introduction into that country, and enjoyed a wide popularity as a game for boys and girls before the Civil War (see Miss Alcott’s Little Women, cap. 12). American croquet is quite distinct from the modern English game. It is played on a lawn 60 ft. by 30, and preserves the old-fashioned English arrangement of ten hoops, including a central “cage” of two hoops. The balls, coloured red, white, blue and black, are 3½ in. in diameter, and the hoops are from 3½ to 4½ in. wide, according to the skill of the players. This game, however, is not taken seriously in the United States; the Official Croquet Guide of Mr. Charles Jacobus emphasizes “the ease with which the game can be established,” since almost every country home has a grass plot, and “no elaboration is needed.” The scientific game of croquet in the United States is known as “roque.” Under this title a still greater departure from the English game has been elaborated on quite independent lines from those of the English Croquet Association since 1882, in which year the National Roque Association was formed. Roque also suffered from the popularity of lawn tennis, but since 1897 it has developed almost as fast as croquet in England. A great national championship tournament is held in Norwich, Conn.,
every August, and the game—which is fully as scientific as modern English croquet—has numerous devotees, especially in New England.

Roque is played, not on grass, but on a prepared surface something like a cinder tennis-court. The standard ground, as adopted by the National Association in 1903, is hexagonal in shape, with ten arches (hoops) and two stakes (peggs) as shown in diagram 2. The length is 60 ft., width 30, and the "corner pieces" are 6 ft. long. An essential feature of the ground is that it is surrounded by a raised wooden border, often lined with india-rubber to facilitate the rebound of the ball, and it is permissible to play a "carom" (or rebounding shot) off this board; a skillful player can often thus hit a ball which is wired to a direct shot. A boundary line is marked 28 in. inside the border, on which a ball coming to rest outside it must be replaced. The hoops are run in the order marked on the diagram, so that the game consists of 36 points. Red and white are always partners against blue and black, and the essential features and tactics of the game are, mutatis mutandis, the same as in modern English croquet—i.e. the skillful player goes always for a break and utilizes one or both of the opponent's balls in making it. The balls are 3 1/2 in. in diameter, of hard rubber or composition, and the arches are 3 1/2 or 3 3/4 in. wide for first- and second-class players respectively; they are made of steel 1 1/2 in. in diameter and stand about 8 in. out of the ground. The stakes are 1 in. in diameter and only 1 1/2 in. above the ground. The mallets are much shorter than those commonly employed in England, the majority of players using only one hand, though the two-handed "pendulum stroke," played between the legs, finds an increasingly large number of adherents, on account of the greater accuracy which it gives. The "jump shot" is a necessary part of the player's equipment, as dead wiring is allowed; it is supplemented by the carom off the border or off a stake or arch, and roque players justly claim that their game is more like billiards than any other out-of-door game.

The game of roque is opened by scoring (stringing) for lead from an imaginary line through the middle wicket (cage), the player whose ball rests nearest the southern boundary line having the choice of lead and balls. The balls are then placed on the four corner spots marked A in diagram, partner balls being diagonally opposite one another, and the starting ball having the choice of either of the upper corners. The leader, say, red, usually begins by shooting at white; if he misses, a carom off the border will leave him somewhere near his partner, blue. White then shoots at red or blue, with probably a similar result. Blue is then "in," with a certain roquet and the choice of laying for red or going for an immediate break himself. The general strategy of the game corresponds to that of croquet, the most important differences being that "peging out" is not allowed, and that on the small ground with its ten arches and two stakes the three-ball break is usually adopted, the next player or "danger ball" being wired at the earliest opportunity.

**CRORE** (Hindustani karor), an Anglo-Indian term for a hundred *lakhs* or ten million. It is in common use for statistics of trade and especially coinage. In the days when the rupee was worth its face value of 25, a crore of rupees was exactly worth a million sterling, but now that the rupee is fixed at 15 to the £1, a crore is only worth £666,666.

**CROSBY, HOWARD** (1826–1891), American preacher and teacher, great-grandson of Judge Joseph Crosby of Massachusetts and of Gen. William Floyd of New York, a signer of the Declaration of Independence, was born in New York City on the 27th of February 1826. He graduated in 1844 from the University of the City of New York (now New York University); became professor of Greek there in 1851, and in 1859 became professor of Greek in Rutgers College, New Brunswick, New Jersey, where two years later he was ordained pastor of the first Presbyterian church. From 1870 to 1881 he was chancellor of the University of the City of New York; from 1872 to 1881 was one of the American revisers of the English version of the New Testament; and in 1873 was moderator of the general assembly of the Presbyterian Church. He took a prominent part in politics, urged excise reform, proposed "total abstinence," was one of the founders and was the first president of the New York Society for the Prevention of Crime, and pleaded for better management of Indian affairs and for international copyright. Among his publications are *The Lands of the Moslem* (1851), *Bible Companion* (1870), *Jesus: His Life and Works* (1871), *True Temperance Reform* (1879), *True Humanity of Christ* (1880), and commentaries on the book of Joshua (1875), Nehemiah (1877) and the New Testament (1883). His son, Ernest Howard Crosby (1856–1907), was a social reformer, and was born in New York City on the 4th of November 1856. He graduated at the University of the City of New York in 1876 and at Columbia Law School in 1878; served in the New York Assembly in 1887–1889, securing the passage of a high-licence bill; in 1889–1894 was a judge of the Mixed Tribunal at Alexandria, Egypt, resigning upon coming under the influence of Tolstoy; and died in New York City on the 3rd of January 1907. He was the first president (1894) of the Social Reform Club of New York City, and was president in 1900–1905 of the New York Anti-Imperialist League; was a leader in settlement work and in opposition to child labour, and was a disciple of Tolstoy as to universal peace and non-resistance, and of Henry George in his belief in the "single tax" principle. His writings, many of which are in the manner of Walt Whitman, comprise *Plain Talk in Psalm and Parable* (1899), *Swords and Ploughshares* (1902), and *Broadcast* (1905), all in verse; an anti-military novel, *Captain Jinks, Hero* (1902); and essays on Tolstoy (1904 and 1905) and on Garrison (1905).

**CROSS, and CRUCIFIXION** (Lat. *crux, crucis*?). The meaning ordinarily attached to the word "cross" is that of a figure composed of two or more lines which intersect, or touch each other transversely. Thus, two pieces of wood, or other material, so placed in juxtaposition to one another, are understood to form a cross. It should be noted, however, that Lipsius and other writers speak of the single upright stake to which criminals were bound as a cross, and to such a stake the name of *crux simplex* has been applied. The usual conception, however, is that of a compound figure.

Punishment by crucifixion was widely employed in ancient times. It is known to have been used by nations such as those of Assyria, Egypt, Persia, by the Greeks, Carthaginians,

---

CROSS

is a common Egyptian device, and is indeed often called the Egyptian cross. The *stavika* has a very wide range of distribution, and is found on all kinds of objects. It was used as a religious emblem in India and China at least ten centuries before the Christian era, and is met with on Buddhist coins and inscriptions from various parts of India. A fine sepulchral urn found at Shropham in Norfolk, and now in the British Museum, has three bands of cruciform ornaments round it. The two uppermost of these are plain circles, each of which contains a plain cross; the lowest band is formed of a series of squares, in each of which is a *svastika*. In the Vatican Museum there is an Etruscan fibula of gold which is marked with the *svastika*, but it is a device of such common occurrence on objects of pre-Christian origin, that it is hardly necessary to specify individual instances. The cross, as a device in different forms, and often enclosed in a circle, is of frequent occurrence on coins and medals of pre-Christian date in France and elsewhere. Indeed, objects marked with pre-Christian crosses are to be seen in every important museum.

The death of Christ on a cross necessarily conferred a new significance on the figure, which had hitherto been associated with a conception of religion not merely non-Christian, but in its essence often directly opposed to it. The Christians of early times were wont to trace, in things around them, hidden prophetic allusions to the truth of their faith, and such a testimony they seem to have readily recognized in the use of the cross as a religious emblem by those whose employment of it betokened a belief most repugnant to their own. The adoption by them of such forms, for example, as the tau cross and the *svastika* or *fylfot* was no doubt influenced by the idea of the occult Christian significance which they thought they recognized in those forms, and which they could use with a special meaning among themselves, without at the same time arousing the ill-feeling or shocking the sentiment of those among whom they lived.

It was not till the time of Constantine that the cross was publicly used as the symbol of the Christian religion. Till then its employment had been restricted, and private among the Christians themselves. Under Constantine it became the acknowledged symbol of Christianity, in the same way in which, long afterwards, the crescent was adopted as the symbol of the Mahomedan religion. Constantine's action was no doubt influenced by the vision which he believed he saw of the cross in the sky with the accompanying words in τοίχω σακα, as well as by the story of the discovery of the true cross by his mother St Helena in the year 326. The legend is that, when visiting the holy places in Palestine, St Helena was guided to the site of the crucifixion by an aged Jew who had inherited traditional knowledge as to its position. After the ground had been dug to a considerable depth, three crosses were found, as well as the superscription placed over the Saviour's head on the cross, and the nails with which he had been crucified. The cross of the Lord was distinguished from the other two by the working of a miracle on a crippled woman who was stretched upon it. Fastening, or 'invention,' of the holy cross by St Helena is commemorated in the festival on the 3rd of May, called the 'Invention of the Holy Cross.' The legend was widely accepted as true, and is related by writers such as St Ambrose, Rufinus, Sulpicius Severus and others, but it is discounted by the existence of an older legend, according to which the true cross was found in the reign of Tiberius, and while St James the Great was bishop of Jerusalem, by Protonice, the wife of Claudius.

In recent times an attempt has been made to reconcile the two accounts, by attributing to St Helena the rediscovery of the true cross, originally found by Protonice, and which had been buried again on the spot. A change was made in 1895 in the *Diario Romano*, when the word *Ritrovamento* was substituted for that of *Invenzione*, in the name of the festival of the 3rd of May. After St Helena's discovery a church was built upon the site, and in it she placed the greater portion of the cross. The remaining portion she conveyed to Byzantium, and hence Constantine sent a piece to Rome, where it is said to be still preserved in the church of S. Croce in Gerusalemme.

Macedonians, and from very early times by the Romans. It has been thought, too, that crucifixion was also used by the Jews themselves, and that there was an allusion to it (Deut. xxi. 22, 23) as a punishment to be inflicted.

Two methods were followed in the infliction of the punishment of crucifixion. In both of these the criminal was first of all usually stripped naked, and bound to an upright stake, where he was so cruelly scourged with an implement, formed of strips of leather having pieces of iron, or some other hard material, at their ends, that not merely was the flesh often stripped from the bones, but even the entrails partly protruded, and the anatomy of the body was disclosed. In this pitiable state he was reclothed, and, if able to do so, was made to drag the stake to the place of execution, where he was either fastened to it, or impaled upon it, and left to die. In this method, where a single stake was employed, we have the *crux simplex* of Lipsius. The other method is that with which we are more familiar, and which is described in the New Testament account of the crucifixion of Jesus Christ. In such a case, after the scourging at the stake, the criminal was made to carry a gibbet, formed of two transverse bars of wood, to the place of execution, and he was then fastened to it by iron nails driven through the outstretched arms and through the ankles. Sometimes this was done as the cross lay on the ground, and it was then lifted into position. In other cases the criminal was made to ascend by a ladder, and was then fastened to the cross. Probably the feebleness, or state of collapse, from which the criminal must often have suffered, had much to do in deciding this. It is not quite clear which of these two plans was followed in the case of the crucifixion of Christ, but the more general opinion has been that He was nailed to the cross on the ground, and that it was then lifted into position. The contrary opinion, has, however, prevailed to some extent, and there are representations of the crucifixion which depict Him as mounting a ladder placed against the cross. Such representations may, however, have been due to a pious desire, on the part of their authors, to emphasize the voluntary offering of Himself as the Saviour of the World, rather than as being intended for actual pictures of the scene itself. It may be noted, however, that among the "Emblems of the Passion," as they are called, and which were very favourite devices in the middle ages, the ladder is not infrequently found in conjunction with the crown of thorns, nails, spear, &c.

From its simplicity of form, the cross has been used both as a religious symbol and as an ornament, from the dawn of man's civilization. Various objects, dating from periods long anterior to the Christian era, have been found, marked with crosses of different designs, in almost every part of the old world. India, Syria, Persia and Egypt have all yielded numberless examples, while numerous instances, dating from the later Stone Age to Christian times, have been found in nearly every part of Europe. The use of the cross as a religious symbol in pre-Christian times, and among non-Christian peoples, may probably be regarded as almost universal, and in very many cases it was connected with some form of nature worship.

| Two of the forms of the pre-Christian cross which are perhaps most frequently met with are the tau cross, so named from its resemblance to the Greek capital letter τ, and the *svastika* or *fylfot* which, also called "Gammadion" owing to its form being that of four Greek capital letters γαμμαι ρισειτε placed together. The tau cross

1 The acceptance of this word as the English equivalent for this peculiar form of the cross rests only, according to the *New English Dictionary*, on a MS. of about 1500 in the Lansdowne collection, which gives details for the erection of a memorial stained-glass window. It is in the neddorv panne under ther I kne, . . . . . . . in the sketch given with the instructions a cross occupies the space indicated. It is a question, therefore, whether "fylfot" is a name for any device suitable to fill the foot of any design, or the name peculiar to this particular form of cross. The word is not, as was formerly accepted, a corruption of the O. Eng. *feuerfelte*, four-footed.
which was built to receive so precious a relic. It is exposed for the veneration of the faithful on Good Friday, 3rd of May, and the third Sunday in Lent, each year.

Another festival of the holy cross is kept on the 14th of September, and is known as the "Exaltation of the Holy Cross." It seems to have originated with the dedication, in the year 335, of the churches built on the sites of the crucifixion and the holy sepulchre. The observance of this festival passed from Jerusalem to Constantinople, and thence to Rome, where it appears to have been introduced in the 7th century. By some it is thought that the feast of the Exaltation of the Cross had its origin in Constantine's vision of the cross in the sky in the year 317, but whether it originated then, or, as is more generally supposed, at the dedication of the churches at Jerusalem, there is no doubt that it was afterwards kept with much greater solemnity in consequence of the recovery of the portion of the cross St Helena had left at Jerusalem, which had been taken away in the Persian victory, and was restored to Jerusalem by Heraclitus in 627. Pope Clement VIII. (1592-1604) raised the festival of the Exaltation of the Holy Cross to the dignity, liturgically known as the Day of Divine Mercy.

Before leaving the story of St Helena and the cross, it may be convenient to allude briefly to the superscription placed over the Saviour's head, and the nails, which it is said she found with the cross. The earlier tradition as to the superscription is obscure, but it would seem that it ought to be considered part of the relic which Constantine sent to Rome. By some means it was entirely lost sight of until the year 1492, when it is said that it was accidentally found in a vault in the church of S. Croce in Gerusalemme at Rome. Pope Alexander III. published a bull certifying to the truth of this re-discovery of the relic, and authenticated its character.

As regards the nails, a question has arisen whether there were three or four. In the earliest pictures of the Crucifixion the feet are shown as separately nailed to the cross, but at a later period they are crossed, and a single nail fixes them. In the former case there would be four nails, and in the latter only three. Four is the number generally accepted, and it is said that one was cast by St Helena into the sea, during a storm, in order to subdue the waves, another is said (but the legend cannot be traced far back) to have been beaten out into the iron circle of the crown of Lombardy, while the remaining two are reputed to be preserved among the relics at Milan and Trier respectively.

The employment of the cross as the Christian symbol has been so manifold in its variety and application, and the different forms to which the figure has been adapted and elaborated are so complex, that it is only possible to deal with the outline of the subject.

We learn from Tertullian and other early Christian writers of the constant use which the Christians of those days made of the sign of the cross. Tertullian (De Cor. Mil. cap. iil.) says: "At each journey and progress, at each coming in and going out, at the putting on of shoes, at the bath, at meals, at the kindling of lights, at bedtime, at sitting down, whatsoever occupation engages us, we mark the brow with the sign of the cross. With so frequent an application of the sign of the cross in their domestic life, it would be strange if we did not find that it was very frequently used in the public worship of the church. The earliest liturgical forms are comparatively late, and are without rubrics, but the allusions by different writers in early times to the ceremonial use of the sign of the cross in the public services are so numerous, and so much importance was attached to it, that we are left in no manner of doubt on the point. St Augustine, indeed, speaks of the sacraments as not duly ministered if the use of the sign of the cross were absent from their ministration (Hom. cxviii. in S. Joan.). Of the later liturgical use of the sign of the cross there is little need to speak, as a reference to the service books of the Greek and Latin churches will plainly indicate the frequency of, and the importance attached to, its employment. Its occasional use is retained by the Lutherans, and in the Church of England it is authori-tatively used at baptism, and at the "sacring" or anointing of the sovereign at the coronation.

Passing from the sign to the material figures of the cross, a very usual classification distinguishes three main forms: (1) the crux immissa, or capitata (fig. 3) known also as the Latin cross, or if each limb is of the same length, + (fig. 4) as the Greek cross; (2) the crux decussata, formed like the letter X, and (3) the crux commissa or tau cross, already mentioned. It was on a crux immissa that Christ is believed to have been crucified. The crux decussata is known as St Andrew's cross, from the tradition that St Andrew was put to death on a cross of that form. The crux commissa is often called St Anthony's cross, probably only because it resembles the crutch with which the great hermit is generally depicted.

The cross in one form or other appears, appropriately, on the flags and ensigns of many Christian countries. The English cross of St George is a plain red cross on a white ground, the Scottish cross of St Andrew is a plain diagonal white cross on a blue ground, and the Irish cross of St Patrick is a plain diagonal red cross on a white ground. These three crosses are combined in the Union Jack (see Flag).

The cross has also been adopted by many orders of knighthood. Perhaps the best known of these is the cross of the knights of Malta. It is a white cross of eight points on a black ground (fig. 5) and is the proper Maltese cross, a name which is often wrongly applied to the cross pâle (fig. 6). The knights of the Garter use the cross of St George, as do those of the order of St Michael and St George, the knights of the Thistle use St Andrew's cross, and those of St Patrick the cross of St Patrick charged with a shamrock leaf. The cross of the Danish order of the Dannebrog (fig. 7) affords a good example of this use of the cross. It is in form a white cross pâlée, superimposed upon a red one of the same form, and is surmounted by the royal cipher and crown, and has upon its surface the royal cipher repeated, and the legend, or motto, "Gud og Kongen" = " God and the King." (For crosses of monastic orders see Costum.)

Akin to the crosses of knightly orders are those which figure as charges on coats of arms. The science of heraldry evolved a wonderful variety of cross-forms during the period it held sway in the middle ages. The different forms of cross used in heraldry are, in fact, so numerous that it is only the larger works on that subject which attempt to record them all. For such crosses see Heraldry.

In the middle ages the cross form, in one way or another, was predominant everywhere, and was introduced whenever opportunity offered itself for doing so. The larger churches were planned on its outline, so that the ridge line of their roofs proclaimed it far and wide. This was more particularly followed in the north of Europe, but when it was first introduced is not quite certain. All the ancient cathedral churches of England and Wales are cruciform in plan, except Llandaff.

The artistic skill and ingenuity of the medieval designer has produced cross designs of endless variety, and of singular elegance and beauty. Some of the most beautiful of these designs are the gable crosses of the old churches. Fig. 8 shows the west gable cross of Washburn church, Worcestershire; fig. 9 that of the nave of Castle Acre church, Norfolk; and fig. 10 the east gable cross of Hethersett church in that county. They may be taken as good examples of a type of cross which is often of great beauty, but it is overlooked, owing to its bad position for observation.
Other architectural crosses, of great beauty of design, are those which occur on the grave slabs of the middle ages. Instances of a plainer type occur in Saxon times, but it was not till after the 11th century that they were fashioned after the intricate and beautiful designs with which our ancient churches are, as a rule, so plentifully supplied. Sometimes these crosses are incised in the slab, and almost as often they are executed in low relief. The long shaft of the cross is most commonly plain, but there are a very large number of instances in which this is not so, and in which branches, with leaf designs, are thrown out at intervals the entire length of the shaft. In some cases the shaft rises from a series of steps at its base, and in such a case the name of a Calvary is applied to it. Fig. 11, from Strad- sett church, Norfol, and fig. 12 from Bosbury church, Hereford- shire, are good examples of the designs at the head of sepulchral crosses. Often, by the side of the cross, an emblem or symbol is placed, denoting the calling in life of the person commemorated. Thus a sword is placed to indicate a knight or soldier, a chalice for a priest, and so forth; but it would be travelling beyond the scope of this article to enter into a discussion as to such symbols.

Of upright standing crosses, the Irish and Iona types are well known, and their great artistic beauty and elaboration and excellence of sculpture are universally recognized. These crosses are sometimes spoken of as “Runic Crosses”; and the interlacing knotwork design with which many of them are ornamented is also at times spoken of as “Runic.” This is an erroneous application of the word, and has arisen from the fact that some of these crosses bear inscriptions in Runic characters. Standing crosses, of different kinds, were commonly set up in every suitable place during the middle ages, as the mutilated bases and shafts still remaining readily testify. Such crosses were erected in the centre of the market place, in the churchyard, on the village green, or as boundary stones, or marks to guide the traveller. Some, like the Black Friars cross at Hereford, were preaching stations, others, like the beautiful Eleanor crosses at Northampton, Geddington and Waltham, were commemorative in character. Of these latter crosses, which marked the places where the funeral procession of Queen Eleanor halted, there were originally ten or more, erected between 1241 and 1264. They were placed at Lincoln, Northampton, Stony Stratford, Woburn, Dunstable, St Albans, Waltham and London (Cheapside and Charing Cross). The cross at Geddington differs in outline from those at Northampton and Waltham, and it is not recorded on the roll of accounts for the nine others, all of which are mentioned, but there is no real doubt that it commemorates the resting of the coffin of the queen in Geddington church on its way from Harby. These crosses, like the Black Friars cross at Hereford, are elaborate architectural erections, and very similar to them in this respect are the beautiful market crosses at Winchester, Chichester, Salisbury, Devizes, Shepton Mallet, Leighton Buzzard, &c. Of churchyard crosses, as distinguished from memorial crosses in churchyards, one only is believed to have escaped in a perfect condition the ravages of time, and the fanaticism of the past. It stands in the churchyard of Somery, in Lincolnshire (Tennyson’s birthplace), and is a tall shaft surmounted by a pedimented tabernacle, on one side of which is the crucifixion, and on the other the figure of the Virgin and Child. Churchyard crosses may have been used as occasional preaching stations, for reading the Gospel in the Palm Sunday procession, and generally for public proclamations, made usually at the conclusion of the chief Sunday morning service, much in the same way that market crosses were used on market days as places for proclamations in the towns.

Of the ecclesiastical use of the sign of the cross mention has already been made, and it is desirable to mention briefly one or two instances of the ecclesiastical use of the cross itself. From a fairly early period it has been the prerogative of an archbishop or metropolitan, to have a cross borne before him within the limits of his province. The question urged between the archbishops of Canterbury and York about the carrying of their crosses before them, in each other’s province, was a fruitful source of controversy in the middle ages. The archiepiscopal cross carried by the archbishop is sometimes confused with the crozier or pastoral staff. The latter, which is formed with a crook at the end, is quite distinct, and is used by archbishops and bishops alike, who bear it with the left hand in processions, and when blessing the people. The archiepiscopal cross, on the contrary, is always borne before the archbishop, or during the vacancy of the archiepiscopae see before the guardian of the spiritualities sede vacante. The bishop of Dol in Brittany, of ordinary diocesan bishops, alone possessed the privilege of having a cross borne before him in his diocese. Good illustrations of the archiepiscopal cross occur on the monumental brasses of Archbishop Waldeby, of York (1397), at Westminster Abbey, and of Archbishop Cranley, of Dublin (1417) in New College chapel, Oxford.

The custom of carrying a cross at the head of an ecclesiastical procession can be traced back to the end of the 4th century. The cross was originally taken from the altar, and raised on a pole, and borne before the procession. Afterwards a separate cross was provided for processions, and in the 13th and 14th centuries this was not the case, the altar cross continued to be used till quite a late period. A direction to this effect occurs as late as 1829, in the Ritual published for the diocese of La Rochelle in that year. In England altar crosses were not very usual in the middle ages. As a personal ornament the cross came into common use, and was usually worn suspended by a chain from the neck. A cross of this kind, of very great interest and beauty, was found about 1690, on the breast of Queen Dagmar, the wife of Waldemar II., king of Denmark (d. 1213). It is of Byzantine design and workmanship, and is of enamelled gold (fig. 13 shows both sides of it); on one side is the Crucifixion, and on the other side the half figure of our Lord in the centre, with the Virgin and St John the Evangelist on either side, and St Chrysostom and St Basil above and below. From the way in which such crosses were worn, hanging over the chest, they are called pectoral crosses. At the present day a pectoral cross forms part of the recognized insignia of a Roman Catholic bishop, and is worn by him over his robes, but this official use of the pectoral cross is not ancient, and no instance is known of it in England before the Reformation.
CROSSBILL—CROSSEN

The custom appears to have taken rise in the 16th century on the continent. It was not unusual to wear cruciform reliquaries, as objects of personal adornment, and such a reliquary was found on the body of St. Cuthbert, when his tomb was opened in 1827, but it was placed under, and not over his episcopal vestments, and formed no part of his bishop's attire. The custom or wearing a pectoral cross over ecclesiastical robes has, curiously enough, been copied from the comparatively modern Roman Catholic usage by the Lutheran bishops and superintendents in Scandinavia and Prussia; and in Sweden the cross is delivered to the new bishop, on his installation in office, by the archbishop of Upsala, together with the mitre and crozier. Within the last generation the use of a pectoral cross, worn over their robes as part of the insignia of the episcopal office, has been adopted by some bishops of the Church of England, but it has no ancient sanction or authority.

CROSSBILL (Fr. Bec-croisé, Ger. Kreuzenschädel), the name given to a genus of birds, belonging to the family Fringillidae, or finches, from the unique peculiarity they possess among the whole class of having the horny sheaths of the bill crossing one another obliquely,1 whence the appellation Loxia (Loxos, obliquus), conferred by Gesner on the group and continued by Linnaeus. At first sight this singular structure appears so like a deformity that writers have not been wanting to account it such,2 ignorant of its being a piece of mechanism most beautifully adapted to the habits of the bird, enabling it to extract with the greatest ease, from fir-cones or fleshy fruits, the seeds which form its usual and almost invariable food. Its mode of using this unique instrument seems to have been first described by Townsend (Tracts on Nat. Hist., p. 116, London, 1799), but only partially, and it was Yarrell who, in 1829 (Zool. Journ., iv. pp. 457-495, pl. xiv. figs. 1-7), explained fully the means whereby the jaws and the muscles which direct their movements become so effective in riving asunder cones or apples, while at the proper moment the scoop-like tongue is instantaneously thrust out and withdrawn, conveying the hitherto protected seed to the bird's mouth. The articulation of the mandible to the quadrato-bone is such as to allow of a very considerable amount of lateral play, and, by a particular arrangement of the muscles which move the former, it comes to pass that so soon as the bird opens its mouth the point of the mandible is brought immediately opposite to that of the maxilla (which itself is movable vertically), instead of crossing or overlapping it—the usual position when the mouth is closed. The two points thus meeting, the bill is inserted between the scales or into the pome, but on opening the mouth still more widely, the lateral motion of the mandible is once more brought to bear with great force to wrench aside the portion of the fruit attacked, and then the action of the tongue completes the operation, which is so rapidly performed as to escape scrutiny, except by close inspection. Fortunately the birds soon become tame in confinement, and a little patience will enable an attentive observer to satisfy himself as to the process, the result of which at first seems almost as unaccountable as that of a clever conjuring trick.

The common crossbill of the Palaeartic region (Loxia curvirostra) is about the size of a skylark, but more stoutly built. The young (which on leaving the nest have not the tips of the bill crossed) are of a dull olive colour with indistinct dark stripes on the lower parts, and the quills of the wings and tail dusky. After the first moult the difference between the sexes is shown by the hens inclining to yellowish-green, while the cocks become diversified by orange-yellow and red, their plumage finally deepening into a rich crimson-red, varied in places by a flame-colour. Their glowing hues, are, however, speedily lost by examples which may be kept in confinement, and are replaced by a dull orange, or in some cases by a bright golden-yellow, and specimens have, though rarely, occurred in a wild state exhibiting the same tints. The cause of these changes is at present obscure, if not unknown, and it must be admitted that their sequence has been disputed by some excellent authorities, but the balance of evidence is certainly in favour of the above statement. Depending mainly for food on the seeds of conifers, the movements of crossbills are irregular beyond those of most birds, and they would seldom move in any direction and at any season in quest of a staple subsistence. But the pips of apples are also a favourite dainty, and it is recorded by the old chronicler Matthew Paris (Hist. Angl. MS. fol. 252), that in 1251 the orchards of England were ravaged by birds, “pomorum grana, & non aulii de eidem pomis comedentes,” which, from his description, “Habebant autem partes rostri cancellatas, per quas poma quasi forcipil vel culter il dividabant,” could be none other but crossbills. Notice of a like visitation in 1503 is recorded, but of late it has become evident that not a year passes without crossbills being observed in some part or other of England, while in certain localities in Scotland they seem to breed annually. The nest is rather rudely constructed, and the eggs, generally four in number, resemble those of the greenfinch, but are larger in size. This species ranges throughout the continent of Europe,3 and occurs in the islands of the Mediterranean and in the firwoods of the Atlas. In Asia it would seem to extend to Kamtschatka and Japan, keeping mainly to the forest-tracts.

Three other forms of the genus also inhabit the Old World—two of them so closely resembling the common bird that their specific validity has been often questioned. The first of these, of large stature, the parrot-crossbill (L. pityophytopicus), comes occasionally to Great Britain, presumably from Scandinavia, where it is known to breed. The second (L. himalayana), which is a good deal smaller, is only known from the Himalaya Mountains. The third, the two-barred crossbill (L. laciniosa), is very distinct, and its proper home seems to be the most northern forests of the Russian empire, but it has occasionally occurred in western Europe and even in England.

The New World has two birds of the genus. The first (L. americana), representing the common British species, but with a smaller bill, and the males easily recognizable by their more scarlet plumage, ranges from the northern limit of coniferous trees to the highlands of Mexico, or even farther. The other (L. leucopetora) is the equivalent of the two-barred crossbill, but smaller, which twice occurred in England. (A. N.)

CrosSen, or Krossen, a town of Germany, in the kingdom of Prussia, on the Oder, here crossed by a bridge, at the influx of the Bober, 31 m. S.E. of Frankfort-on-Oder by rail. Pop. (1900) 7360. Of the churches in the town three are Protestant

1 This peculiarity is found as an accidental malformation in the crows (Corvidae) and other groups; it is comparable to the monstrosities seen in rabbits and other members of the order Girets, in which the incisor teeth grow to an inordinate length.
2 A medieval legend ascribes the conformation of bill and coloration of plumage to a divine recognition of the bird's pity, bestowed on Christ at the crucifixion.
3 Dr Malme found a small flock on Bear Island (lat. 74° N.), but to this barren spot they must have been driven by stress of weather.
and one Roman Catholic. Besides the modern school (Real-
progymnasium), there are a technical school for viniculture
and fruit-growing and a dairy school. There are manu-
factories of copper and brass ware, cloth, &c; while in
the surrounding country the chief industries are fruit and grape
growing. There is a brisk shipping trade, mainly in wine, fruit
and fish. Crossen was founded in 1005 and was important during
the middle ages as a point of passage across the Oder. It attained
civic rights in 1222, was for a time the capital of a Silesian duchy,
which, on the death of Barbara of Brandenburg, widow of the
last duke, passed to Brandenburg (1482). In May 1886 the town
was devastated by a whirlwind.

CROSSING, in architecture, the term given to the intersection
of the nave and transept, frequently surmounted by a tower or
by a dome on pendentives.

CROSKEY, HENRY WILLIAM (1826-1893), English geologist
and Unitarian minister, was born at Lewes in Sussex, on the
7th of December 1826. After being trained for the ministry at
Manchester New College (1843-1849), he became pastor of
Friargate chapel, Derby, until 1852, when he accepted charge
of a Unitarian congregation in Glasgow. In 1860 he removed
as pastor to Edinburgh, where until the close of his life he was pastor
of the Church of the Messiah. While in Glasgow his interest
was awakened in geology by the perusal of A. C. Ramsay's
Geology of the Isle of Arran, and from 1855 onwards he devoted
his leisure to the pursuit of this science. He became an authority
on glacial geology, and wrote much, especially in conjunction
with David Robertson, on the post-tertiary fossiliferous beds
of Scotland (Trans. Geol. Soc. Glasgow). He also prepared for
the British Association a valuable series of Reports (1837-1892)
on the erratic Blocks of England, Wales and Ireland. In con-
junction with David Robertson and G. S. Brady he wrote the
Monograph of the Post Tertiary Entomocrosta of Scotland, &c.
for the Palaeontographical Society (1874); and he edited H.
Carvill Lewis' Papers and Notes on the Glacial Geology of Great
Britain and Ireland, issued posthumously (1894). He died at
Edgbaston, Birmingham, on the 1st of October 1893.

See H. W. Crossley: his Life and Work, by R. A. Armstrong (with
a chapter on his geological work by Prof. C. Lapworth, 1895).

CROSS RIVER, a river of West Africa, over 500 m. long.
It rises in 6° N., 1° 30' E. in the mountains of Cameroon, and
flows at first N.W. In 8° 48' E., 5° 30' N. are a series of rapids;
below this point the river is navigable for shallow-draught boats.
At 8° 20' E., 6° 10' N., its most northern point, the river turns
S.W. and then S., entering the Gulf of Guinea through the Calabar
estuary. The Calabar river, which rises about 5° 30' N., 8° 30' E.,
has a course parallel to, and 10 to 20 m. east of, the Cross river.
Near its mouth, on its east bank, is the town of Calabar (q.v.).
It enters the estuary in 4° 15' N. The Cross, Calabar, Kwa and
other streams farther east, which rise on the flanks of the
Cameron Mountains, form a large delta. The Calabar and
Kwa rivers are wholly within the British protectorate of Southern
Cameroons, as is the Cross river from its mouth to the rapids
mentioned. The upper course of the river is in German
territory.

CROSS-ROADS, BURIAL AT, in former times the method
of disposing of executed criminals and suicides. At the cross-roads
a rude cross usually stood, and this gave rise to the belief that
these places were looked upon as the best burial-places to
consecrated ground. The real explanation is that the ancient
Teutonic peoples often built their altars at the cross-roads, and as
human sacrifices, especially of criminals, formed part of the
ritual, these spots came to be regarded as execution grounds.
Hence after the introduction of Christianity, criminals and
suicides were buried at the cross-roads during the night, in order
to assimilate as far as possible their funeral to that of the pagans.
An example of a cross-road execution-ground was the famous
Tyburn in London, which stood on the spot where the Oxford,
Edgware and London roads met.

CROSS SPRINGER, in architecture, the block from which the
diagonal ribs of a vault spring or start: the top of the springer
is known as the skewback (see Arch).
previously been on friendly terms, and raze their city to the ground. Shortly afterwards, however, an insurrection took place, by which the disciples of Pythagoras were driven out, and a democracy established. The victory of the Locrions and Phliegones over Crotona in 480 B.C. marked the beginning of its decline. It suffered after this from the attacks of Dionysius I., who became its master for twelve years, of the Brutii, and of Agathocles, and even more from the invasion of Pyrrhus, after which in 277 the Romans obtained possession of it. Livy states that the walls had a length of 12 m. and that about half the area within them had at that time ceased to be inhabited. After the battle of Cannae Crotona revolted from Rome, and Hannibal made it his winter quarters for three years. It was made a colony by the Romans at the end of the war (194 B.C.). After that time but little is heard of it, though Petronius mentions the corrupt morals of its inhabitants; but it continues to be mentioned down to the Gothic wars. The importance of the city was mainly due to its harbour, which, though not a good one, was the only port between Tarentum and Rhegium. The original settlement occupied the hill above it (143 ft.) and later became the acropolis. Its healthy situation was famous in antiquity, and to this was ascribed its superiority in athletics; it was the seat also of a medical school which in the days of Herophilus was considered the foremost in Greece. Of the exact site of the ancient city and its remains practically nothing is known; a few fragments of the productions of its art preserved in private hands at Cotrone are described by F. von Duhn in Notizie degli scavi, 1897, 343 seq.

**CROTONIC ACID (C₃H₆O₃).** Three acids of this empirical formula are known, viz. crotonic acid, isocrotonic acid and methacrylic acid; the constitutional formulae are—

\[
\begin{align*}
\text{HC}_3\text{CO}_2\text{H} & \quad \text{HC}_3\text{CO}_2\text{H} & \quad \text{CH}_2\text{CH}:\text{CHCO}_2\text{H} \\
\text{HC}_3\text{CH} & \quad \text{HC}_3\text{CH} & \quad \text{CH}_2\text{CH}:\text{CHCO}_2\text{H} \\
\text{Crotonic Acid. Isocrotonic Acid. Methacrylic Acid.}
\end{align*}
\]

The isomerism of crotonic and isocrotonic acids is to be explained on the assumption of a different spatial arrangement of the atoms in the molecule (see Stereochemistry).

Crotonic acid, so named from the fact that it was erroneously supposed to be a saponification product of croton oil, may be prepared by the oxidation of croton-aldehyde, CH₂₃CH:CHCHO, obtained by dehydration of the acid, or by treating acetylene successively with sulphuric acid and water; by boiling allyl cyanide with caustic potash; by the distillation of \( \beta \)-oxybutyric acid; by heating paraldehyde with malonic acid and acetic acid to 100°C. (T. Kommenes, Ann., 1883, 228, p. 149).

\[
\text{CH}_3\text{(COOH)}_2 + \text{CH}_2\text{CHO} \rightarrow \text{CH}_2\text{(COOH)}_2 + \text{CH}_2\text{CH}:\text{CHCOOH},
\]

or by heating pyruvic acid with an excess of acetic anhydride and sodium acetate to 160-180°C. (B. Homolka, Ber., 1885, 18, p. 987). It crystallizes in needles (from hot water) which melt at 72°C. and boil at 180-181°C. It is moderately soluble in cold water. It combines directly with bromine, and, with fuming hydrobromic acid at 100°C., it gives chiefly \( \beta \)-bromobutyric acid. With hydriodic acid it gives only \( \beta \)-iodobutyric acid. Potash fusion converts it into acetic acid; nitric acid oxidizes it to acetic and oxalic acids; chromic acid mixture to acetaldehyde and acetic acid, and potassium permanganate to \( \alpha \)-dioxybutyric acid.

Isocrotonic acid (Quartenylic acid) is obtained from \( \beta \)-chlorocrotonic acid, formed when acetoacetic ester is treated with phosphorus pentachloride and the product poured into water, by the action of sodium amalgam (A. Geuther). It is an oil, possessing a smell like that of butyric acid. It boils at 171-19°C., with partial conversion into crotonic acid; the transformation is complete when the acid is heated to 170-180°C. in a sealed tube. Potassium permanganate oxidizes it to \( \beta \)-dioxybutyric acid.

Methacrylic acid was first obtained in the form of its ethyl ester by E. Frankland and B. F. Dupa (Annalen, 1865, 136, p. 12) by acting with phosphorus pentachloride on oxyisobutyric ester (CH₂₂C(OH)-COOH). It is, however, more readily ob-

tained by boiling citra- or meso-brompyroantaratic acids with alcohols. It crystallizes in prisms, which are soluble in water, melt at 16°C., and boil at 160-16°C. When fused with an alkali, it forms propionic acid; with bromine it yields \( \beta \)-bromobutyric acid. Sodium amalgam reduces it to isobutyric acid. A polymeric form of methacrylic acid has been described by F. Engelhorn (Ann., 1880, 200, p. 70).

**CROTON OIL (Crotonis Oleum),** an oil prepared from the seeds of Croton Tiglium, a tree belonging to the natural order Euphorbiaceae, and native or cultivated in India and the Malay Islands. The tree is from 15 to 20 ft. in height, and has few and spreading branches, alternate, oval-oblong leaves, acuminate at the point, and covered when young with stellate hairs, and terminal racemes of small, downy, greenish-yellow, monocious flowers. The male blossoms have five petals and fifteen stamens; the females have no petals but a large oblong ovary bearing three bifid styles. The fruit or capsule is obliquely three-cornered, and about the size of a hazel-nut; it contains three cells each enclosing a seed. The seeds resemble those of the castor-oil plant; they are about half an inch long, and two-fifths of an inch broad, and have a cinnamon-brown, brittle integument; between the two halves of the kernel lie the large cotyledons and radicle. Their boiling point is 172°C. to 173°C. The castor-oil seeds may be of great practical importance. The most obvious difference between them, the castor-oil seeds have a polished and mottled surface. The kernels contain from 50 to 60% of oil, which is obtained by pressing them, when bruised to a pulp, between hot plates. Croton oil is a transparent and viscid liquid of a brownish or pale-yellow tinge, and acid, peculiar and persistent taste, a disagreeable odor and acid reaction. It is soluble in volatile oils, carbon disulphide, and ether, and to some extent in alcohol. It contains acetic, butyric and valeric acids, with glycrides of the same series, and a volatile body, CH₃O₂, tiglic acid, metameric with angelic acid, and identical with methylcrotonic acid, CH₃:CH(CH₂)CO₂H. The oil is due to various volatile acids, which are present to the extent of about 1%. A substance called crotonal appears to be responsible for its external, but not its internal, action. The latter is probably due to crotonolic acid, CH₃:CO₂H, which has active purgative properties.

The maximum dose of croton oil is two minims, one-fourth of that quantity being usually ample. Its active principle is applied to the skin, croton oil acts as a powerful irritant, inducing so much inflammation that definite pustules are formed. The destruction of the true skin gives rise to ugly scars which constitute, together with the pain caused by this application, abundant reason why croton oil should never be employed externally. Despite the pharmacopoeial liminet the practice of a few, it may be said that this employment of croton oil is now entirely without justification or excuse.

Taken internally, even in the minute doses already detailed, croton oil very soon causes much colic and the occurrence of a fluid diarrhoea which usually recurs several times. It is characteristic of this purgative that it is a hydrogogue even in minimal dose, the fluid secretions of the bowel being most markedly increased. The drug appears to act only upon the small intestine. In somewhat larger doses it produces severe gastro-enteritis. The flow of bile is somewhat increased. Such effects may all be produced, even up to the discharge of blood, by the absorption of croton oil from the skin.

The minutness of the dose, the certainty of the action, and the large amount of fluid drained away constitute this the best drug for administration to an unconscious patient (especially in cases of apoplexy, when it is desirable to remove fluid from the body), or to insane patients who refuse to take any drug. One drop of the oil, placed on the back of the tongue, must inevitably be swallowed by reflex action. A dose should never be repeated. The characters of this drug obviously contra-indicate its use in all cases of organic disease or obstruction of the bowel, in pregnancy, or in cases of constipation in children or the aged.

**CROUP,** a name formerly given to diseases characterized by distress in breathing accompanied by a metallic cough and some
hoarseness of speech. It is now known that these symptoms are often associated with diphtheria (q.e.), spasmodic laryngitis (q.e.), and a third disease, spasmodic croup, to which the term is now applied alone. This occurs most frequently in children above two years of age; the child goes to bed quite well, and a few hours later suddenly awakes with great difficulty in inspiration, the chest wall becomes markedly retracted, and there is a metallic cough. The child becomes cyanosed, and, to the inexperienced nurse, seems in an almost moribund condition. In the course of four or five minutes, normal respiration starts again, and the attack is over for the time being; but it may recur several times a day. The seizure may be accompanied by convulsions, and death has occurred from dyspnoea. The best treatment is to plunge the child into a warm bath, and sponge the back and chest with cold water. Subsequently this can be done two or three times a day. Should the cyanosis become very severe, respiration can be restarted by making the child sick, either with a dose of ipecacuanha wine, or by forcing one's finger down the throat. Generally the bowels should be attended to; and the throat carefully examined for enlarged tonsils or adenoids, which if present should be treated.

CROUSAZ, JEAN PIERRE (1663–1750), Swiss writer, was born at Lausanne. He was a many-sided man, whose numerous works on many subjects had a great vogue in their day, but none of which have been described as an intitulé plutôt qu'un créerateur, chiefly because he spent some years at Lausanne the philosophy of Descartes in opposition to the reigning Aristotelianism, and also as a Calvinist pendant (for he was a pastor) of the French abbes of the 18th century. He studied at Geneva, Leyden and Paris, before becoming (1709) professor of philosophy and mathematics at the academy of Lausanne, of which he was four times rector before 1724, when the theological disputes connected with the Consensus led him to accept a chair of philosophy and mathematics at Groningen. In 1726 he was appointed governor to the young prince Frederick of Hesse-Cassel, and in 1735 returned to Lausanne with a good pension. In 1737 he was reinstated in his old chair, which he retained to his death. Gibbon, describing his first stay at Lausanne (1752–1755), writes in his Autobiography, "the logic of de Crousaz prepared me to engage with his master Locke and his antagonist Bayle."

The most important of his works are: Nouvel Essai de logique (1712), Géométrie des lignes et des surfaces rectilignes et circulaires (1716), Traité du beau (1714), Examen du traité de la liberté de penser d'Antoine Collin (1718), De l'éducation des enfants (1722, dedicated to the then Princess of Wales), Examen du philosophe ancien et moderne sur le bon couple, Examen de l'essai de M. Pèpe sur l'homme (1737), an attack on the Leibnitzian theory of that poem, Logique (6 vols., 1741), of the esprit humain (1741), and Réflexions sur l'ouvrage intitulé: La Belle Wolfeine (1743). (W. A. B. C.)

CROW (Dutch, kraai; Ger. Krähe, Fr. corbeau, Lat. corvus), a name most commonly applied in Britain to the bird properly called a rook (Corvus frugilegus), but perhaps originally peculiar to the conger, nowadays usually distinguished as the black or carrion-crow (C. corone). By ornithologists it is also used in a far wider sense, as under the title crows, or Corvidae, is included a vast number of birds from almost all parts of the world, and this family is probably the most highly developed of the whole class Aves. Leaving out of account the best known of these, as the raven, rook, daw, pie and jay, with their immediate allies, our attention will here be confined to the crows in general; and then the species of the family to which the appellation is more strictly applicable may be briefly considered. All authorities admit that the family is very extensive, and is capable of being parted into several groups, but scarcely any two agree. Especially must reserve be exercised as regards the group Streperinae, or piping crows, belonging to the Australian Region, and described by some writers to the shrikes (Laniidae); and the jays too have been erected into a distinct family (Garrulidae), though it seems hardly possible to separate them even as a subfamily from the pies (Picea and its neighbours), which lead almost insensibly to the typical crows (Corvinae). Dismissing these subjects for the present, it will perhaps be most convenient to treat of the two groups which are represented by the genera Pyrrhacorax or choughs, and Corvus or true crows in the most limited sense.

Pyrrhacorax comprehends at least two very good species, which have been needlessly divided generically. The best known of them is the Cornish chough (P. graculus), formerly a denizen of the precipitous cliffs of the south coast of England, of Wales, of the west and north coasts of Ireland, and some of the Hebrides, but now greatly reduced in numbers, and only found in such places as are most free from the intrusion of man or of daws (Corvus monedula), which last seem to be gradually dispossessioning it of its sea-girt strongholds, and its present scarcity is probably in the main due to its persecution by its kindred. In Britain, indeed, it would appear to be only one of the survivors of a more ancient fauna, for in other countries where it is found it has been driven inland, and inhabits the higher mountains of Europe and North Africa. In the Himalayas a larger form occurs, which has been specifically distinguished (P. himalayensis), but whether justifiably so may be doubted. The general colour is a glossy black, and it has the bill and legs bright red. The remaining species (P. alpinus) is altogether a mountaineer, and is the black coccus (C. corone), but it frequents much the same kind of localities, but it does not occur in Britain. The alpine chough is somewhat smaller than its congener, and is easily distinguished by its shorter and brighter yellow bill. Remains of both have been found in French caverns the deposits in which were formed during the "Reindeer Age." Commonly placed by systematists next to Pyrrhacorax is the Australian genus Corvus, represented by a single species (C. melanorhampbus), but this assignment of the bird, which is chiefly a frequenter of woodlands, cannot be admitted without hesitation.

Coming now to what may be literally considered crows, our attention is mainly directed to the black or carrion-crow (C. corone) and the grey, hooded or Royston crow (C. cornix). Both these inhabit Europe, but their range and the time of their appearance are very different. The former, speaking generally, a summer visitor to the south-western part of Europe, and the latter occupies the north-eastern portion—an irregular line drawn diagonally from about the Firth of Clyde to the head of the Adriatic roughly marking their respective distribution. But both are essentially migrants, and hence it follows that while the black crow, as summer comes to an end, retires southward, the grey crow moves downward, and in many districts replaces it during winter. Further than this, it has been indubitably proved that along or near the boundary where these two birds march they not infrequently interbreed, and it is believed that the hybrids, which sometimes wholly resemble one or other of the parents and at other times assume an intermediate plumage, pair indiscriminately among themselves or with the pure stock. Hence it has seemed to many ornithologists who have studied the subject, that these two birds, so long unhappily regarded as distinct species, are only local races of one and the same dimorphic species. No structural difference—or indeed any difference except that of range (already spoken of) and colour—can be detected, and the problem they offer is one of which the solution is exceedingly interesting if not important to zoologists in general. Almost omnivorous in their diet, there is little edible that comes amiss to them, and, except in South America, they are mostly omnivorous. The fish-crow of North America (C. ossifragus) demands a few words, since it betrays a taste for maritime habits beyond that of other species, but the crows of Europe are not averse on occasion to prey cast up by the waters. The house-crow of India (C. splendens) is not very nearly allied to its European namesakes, from which it is stated that they keep apart and do not intermix.

1 The “Consensus ecclesiasticum Helveticarum reformatorum” was a document drawn up in 1675 and imposed in 1724— as a test of strict Protestant orthodoxy as to the doctrine of grace—by Bern on some of its subjects in Lausanne and Vaux.

2 As bearing upon this question may be mentioned the fact that the crow of Australia (C. australis) is divisible into two forms or races, one having the irides white, the other of a dark colour. It is stated that they keep apart and do not intermix.
it can be readily distinguished by its smaller size and the lustrous tints of its darkest feathers, while its confidence in the human race has been so long encouraged by its intercourse with an armed and inoffensive population that it becomes a plague to the European abiding or travelling where it is abundant. Hardly a station or camp in British India is free from a crowd of feathered followers of this species, ready to dispute with the kites and the crows the very meat at the fire.

CROWBERRY, or CRABBEERRY, the English name for a low-growing, heath-like shrub, found on heaths and rocks in Scotland, Ireland and mountainous parts of England. It is known botanically as Empetrum nigrum, and has slender, wiry, spreading branches covered with short, narrow, stiff leaves, the margins of which are recurved so as to form a hollow cylinder concealing the hairy under face of the leaf. A device to avoid excessive loss of water from the leaf under the exposed conditions in which the plant grows. The minute flowers are succeeded by black, edible, berry-like fruits, one-fourth to one-third of an inch in diameter. The plant has a wide distribution, occurring in suitable localities throughout the north temperate zone, and on the Andes of South America.

CROWD, CRUth, CRWTH (Welsh crwth; Fr. cruel; Ger. Chrotta, Hrotta), a medieval stringed instrument derived from the lyre, characterized by a sound-chest having a vaulted back, and an open space left at each side of the strings to allow the hand to pass through in order to stop the strings on the finger-board. The Welsh crwth, which survived until the end of the 18th century, is best represented by a specimen of that date preserved in the Victoria and Albert Museum, and described and illustrated by Carl Engel. It consists of a rectangular sound-chest 2.2 inches long, 0.5 inches wide, and 0.2 inches thick, the body being scooped out of a single block, the flat belly being glued on. Right through the sound-chest on each side of the finger-board is the characteristic open space left for the hand to pass through. There are two circular sound-holes: the left foot of the flat bridge, which lies obliquely across the belly, passes through the left sound-hole and rests inside on the back of the instrument. Six catgut strings fastened to a tail-piece are wound round pegs at the top of the crwth; four of these strings lie over the sound-board and bridge, and are set in vibration by means of a bow, while the two others, used as drones and stretched across the left-hand aperture, are twanged by the thumb of the left hand. The shape and shallowness of the bridge make it impossible to sound a single string with the bow: the arrangement of the strings suggests that they were intended to be sounded in pairs. The instrument is tuned thus: C G B E A D.

At the beginning of the 19th century, William Bingley heard a Welsh peasant playing national airs on a crwth string as follows: C G B E A D. Sir John Hawkins relates that in his time there was still a Welshman living in Anglesea who understood how to play the crwth according to traditional usage. Edward Jones and Daines Barrington both give an account of the Welsh crwth of the 18th century which agrees substantially with Engel’s; the illustration communicated by Daines Barrington is of the strings of the crwth drawn through holes at the top, and fastened on the back, as on the viola da gamba, and other Oriental stringed instruments. On these somewhat scanty authentic records of the instrument, several historians of music have based an illogical claim that the crwth, or rather crotta or rota, mentioned by Venantius Fortunatus as a British instrument, was the Welsh crwth as it was known in the 18th century, and was the earliest bowed instrument, and therefore the ancestor of the violin. The lines of St Paul, who was bishop of Poictiers during the second half of the 15th century, ran thus:—

“Roma nousque lyra, plaudat tibi Barbarus harpa,”

Gracius Aquiliae, crotta Britannia canat.”

The bow is not mentioned by Fortunatus, and there is no ground whatever for believing that the Welsh crwth was played with a bow in the 6th century, or indeed for several centuries after. The stringing of the Welsh crwth with the two drone strings still twanged, the bowing of the body strings, and the invention of the flat bridge which rendered bowing, even in the most highly developed specimens of the 18th century, a difficult task, together with what is known of the early history of the crwth and rota derived from the lyre and guitar, make it impossible that they could have been played by fingers or plectrum. All make the claim untenable. Carl Engel was probably the first to expose the fallacy in his work on the violin.

British lexicographers all agree in deriving the words crwth, crowd and other forms of the name, from some word meaning a bulging protruberant bellifying form, while in German the etymology of the word Chrotta is given as Chrotta or Chrotha, the H.G. for Krwth = rood. Schilderse = tortoise. This word Chrotta was undoubtedly the German equivalent term for the lyre of Hermes, having as back a tortoise-shell, χλωρίσ in Greek and testudo in Latin. Chrotta was also spelt hrotta, and it is easy to see how this became the crwth, a thoughtful and suggestive treatment of the whole subject will be found in Engel’s illustrations. Just as the lyre and cithara, which appeared to be similar to the casual observer, and are indeed still confused at the present day, were instruments differing essentially in construction; so there were, during the early centuries, two lyres, both of which the lyre and cithara were still in transition, two types of crotta or rota. (1) The rota or improved cithara had a body either rectangular with the corners rounded, or rectangular with two, or even three, curved corners, and were built with an added finger-board called the guitar-foild; (2) The tortoise or lyre crotta consisted of a slightly convex back cut out of a block of wood, to which was glued a flat sound-board, at first like the lyre, without intermediary ribs, when the instrument became the crwth, and there was no further development. The first step in the transition of both lyre and cithara was the incorporation of arms and cross-bar into the body, the same outline being preserved; the second was the addition of a finger-board against which the strings were stopped, thus increasing the compass by reststrung; while reststrung is the number of strings to three or four, the third step, observed only in the rota-cithara, consisted in the addition of a neck, as in the guitar. The crwth, crowd, cruth did not undergo this third transition even when the bow was used to set the strings in vibration.

The earliest representation of the crwth yet discovered dates from the Carolingian period. In the miniatures of the Bible of Charles the Bald, preserved in the Bibliothèque Nationale, Paris, one of the musicians of King David is seen stopping strings on the finger-board with his left hand and plucking them with the right (fig. 2); this crwth has only three strings, and may be the crwth of Tenth of which MSS. prepared for Charles the Bald, and preserved during the middle ages in the monastery of St Paul extra muros in Rome (now deposited at the British Museum).

See Anatomy of Music (London, 1766), vol. ii. bk. iii. ch. iii., description and illustrations.

See Musical and Poetical Relicks of Welsh Bards (London, 1794), illustration of crwth, also reproduced by Carl Engel; see note above.

Venantius Fortunatus, Poëmatia, lib. vii. cap. 8, p. 245; see Migne’s Patrologia Sacra, vol. 88.

Drawn from a plate in Auguste de Basta’s Peintures et ornements de la bible de Charles le Chauve.

For the Latin form of the name, see R. de la Chavinede, Peintures et ornements des MSS. de France, et Peintures, ornements, &c., de la bible de Charles le Chauve, in facsimile (Paris, 1883).

in that of St Calixtus in Rome). Other representations are in the miniatures of the 11th, 12th and 13th centuries. To Edward Heron-Allen (De fidicinis opuscula, viii., 1895) is due the discovery of a representation of the Welsh crwth, showing the form still retained in the 18th cent. On the seal of Roger Wade (1316) is a crwth differing but little from the specimen in the Victoria and Albert Museum. The 14th-century instrument had four strings instead of six, and the foot of the bridge does not appear to pass through the sound-hole—a detail which may have escaped the notice of the artist who cut the seal of a original seal lies in the muniment room at Berkeley Castle in Gloucestershire attached to the defance of a bond between the crowder and his devisor Warren de l’Isle, and a cast (see fig. 3) is preserved at the British Museum. The British Museum also possesses two interesting MSS. which concern the crwth: one of these (Add. MS. 14939 ff. 4 and 27) contains an extract made by Lewis Morris in 1742 from an ancient Welsh MS. of "Instructions supposed to be wrote for the Crowd"; the other (Add. MS. 15036 ff. 658 and 66) consists of tracings from a 16th-century Welsh MS. copied in the 16th-century bagpipe, a harp and a krynche, together with the names of those who played the last at the Lasteddled. The drawing is crude, and shows an instrument similar to Roger Wade’s crwth, but having three strings instead of four.

The genealogical tree of the violin given below shows the relative positions of both kinds of rota and crotta.

The Welsh crwth was therefore obviously not an exclusively Welsh instrument, but only a late 18th-century survival in Wales of an archaic instrument once generally popular in Europe but long obsolete. An interesting article on the subject in the German by J. F. W. Wewertem will be found in Monatshefte fur Musik (Berlin, 1881), Nos. 7-12, p. 151, &c.

**CROWE, EYRE EVANS** (1799-1868), English journalist and historian, was born about the year 1799. He commenced his work as a writer for the London newspaper press in connexion with the Morning Chronicle, and he afterwards became a leading contributor to the Examiner and the Daily News. Of the latter journal he was principal editor for some time previous to his death. The department he specially cultivated was that of continental history and foreign politics. He published Lives of Foreign Statesmen (1830), The Greek and the Turk (1853), and Reigns of Louis XVIII. and Charles X. (1854). These were followed by his most important work, the History of France (5 vols., 1858-1868). It was founded upon original sources, in order to consult which the author resided for a considerable time in Paris. He died in London on the 25th of February 1868.

**CROWE, SIR JOSEPH ARCHER** (1825-1886), English consul-official and art critic, son of Eyre Crowe, was born in London on the 25th of October 1828. At an early age he showed considerable aptitude for painting and entered the studio of Delaroche in Paris, where his father was correspondent of the Morning Chronicle. During the Crimean War he was the correspondent of the Illustrated London News, and during the Austro-Italian War represented The Times in Vienna. He was British consul-general in Leipzig from 1860 to 1872, and in Dusseldorf from 1872 to 1880, when he was appointed commercial attaché in Berlin, being transferred in a like capacity to Paris in 1882. In 1883 he was secretary to the Danube Conference in London; in 1889 plenipotentiary at the Samoa Conference in Berlin; and in 1890 British envoy at the Telegraph Congress in Paris, in which year he was made K.C.M.G. During a sojourn in Italy, 1846-1847, he cemented a lifelong friendship with the Italian critic Giovanni Battista Cavalcaselle (1820-1897), and together they produced several historical works on art of classic importance, notably Early Flemish Painters (London, 1857); A New History of Painting in Italy from the Second to the Sixteenth Century (London, 1864-1871, 5 vols.). In 1865 Crowe published Reminiscences of Thirty-Five Years of My Life. He died at Schloss Gamburg in Bavaria on the 6th of September 1896.

Crowe and Cavalcaselle’s great History of Painting was under revision by Crowe up to the time of his death, and then by S. A. Strong (d. 1904) and Langton Douglas, who in 1903 brought out vols. i. and ii. of Murray’s new six-volume edition, the third vol., edited by Langton Douglas, appearing in 1909. A reprint of the original edition, brought up to date by annotations by Edward Huttons, was published by Dent in 3 vols. in 1909.

**CROW INDIANS, or ABSAROKAS** (the name for a species of hawk), a tribe of North American Indians of Siouan stock. They are now settled to the number of some 180o in a reservation in southern Montana to the south of the Yellowstone river. Their original range included this reservation and extended eastward and southward, and no part of the country for hundreds of miles around was safe from their raids. They have ever been known as marauders and horse-stealers, and, though they have generally been cunning enough to avoid open war with the whites, they have roamed through the country whenever opportunity served. Physically they are tall and athletic, with very dark complexions.

**CROWLAND, or CROWLY, a market-town in the S. Kesteven or Stamford parliamentary division of Lincolnshire, England; in a low fen district on the river Welland, 8 m. N.E. of Peterborough, and 4 m. from Postland station on the March-Spalding line of the Great Northern and Great Eastern railways, and Fenkleir on the Great Northern. Pop. (1901) 2747. A monastery was founded here in 716 by King Æthelbald, in honour of St. Guthlac of Mercia (d. 714), a young nobleman who became a hermit and lived here, and, it was said, had foretold Æthelbald’s accession to the throne. The site of St. Guthlac’s cell, not far from the abbey, is known as Anchor (anchorite’s) Church Hill. After the abbey had suffered from the Danish incursions in 870, and had been burnt in that year and in 1091, a fine Norman abbey was raised in 1113. Remains of this building appear in the ruined nave and tower arch, but the most splendid fragment is the west front, of Early English date, with Perpendicular restoration. The west tower is principally in this style. The north aisle is restored and used as the parish church. Among the abbeys was Insulphus (1085-1109), to whom was formerly attributed the Historia Monasterii Crowlandensis. A curious triangular bridge remains, apparently of the 14th century, but referred originally to the middle of the 9th century, which spanned three streams now covered and affords three footways which meet at an apex in the middle.

The town of Crowland grew up round the abbey. By a charter dated 716, Æthelbald granted the isle of Crowland, free from all secular services, to the abbey with a gift of money, and leave to build and enclose the town. The privileges thus...
obtained were confirmed by numerous royal charters extending over a period of nearly 800 years. Under Abbot Ægelric the fens were filled, the monastery grew rich, and the town increased in size, enormous tracts of land being held by the abbey at the Domesday Survey. The town was nearly destroyed by fire (1469-1476), but the abbey tenants were given money to rebuild it. By virtue of his office the abbot had a seat in parliament, but the town was never a parliamentary borough. Abbot Ralph Mershe in 1257 obtained a grant of a market every Wednesday, confirmed by Henry IV. in 1421, but it was afterwards moved to Thorney. The annual fair of St Bartholomew, which originally lasted twelve days, was first mentioned in Henry III.’s confirmatory charter of 1227. The dissolution of the monastery in 1539 was fatal to the progress of the town, which had prospered under the thrifty rule of the monks, and it rapidly sank into the position of an unimportant village. The abbey lands were granted by Edward VI. to Lord Clinton, from whose family they passed in 1671 to the Orby family. The inhabitants formerly carried on considerable trade in fish and wild fowl.

CROWLEY, ROBERT (1558?–1588), English religious and social reformer, was born in Gloucestershire, and educated at Magdalen College, Oxford, of which he was successively dey and fellow. Coming to London, he set up a printing-office in Ely Rents, Holborn, where he printed many of his own writings. As a typographer, his most notable production was an edition of Pierce Plowman in 1550, and some of the earliest Welsh printed books came from his press. As an author, his first venture seems to have been his “Information and Petition against the Oppressors of the poor Commons of this realm,” which internal evidence shows to have been addressed to the parliament of 1547. It contains a vigorous plea for a further religious reformation, but is more remarkable for its attack on the “more than Turkish tyranny” of the landlords and capitalists of that day. While repudiating communism, Crowley was a Christian Socialist, and warmly approved the efforts of Protector Somerset to stop enclosures. In his Way to Wealth, published in 1550, he laments the failure of the Protector’s policy, and attributes it to the organized resistance of the richer classes. In the same year he published (in verse) The Voice of the last Trumpet blown by the seventh Angel: it is a rebuke in twelve “lessons” to twelve different classes of people; and a similar production was his One-and-Thirty Epigrams (1550). These, with Pleasure and Pain (1551), were edited for the Early English Text Society in 1872 (Extra Ser. xv.). The dozen or more other works which Crowley published are more distinctly theological: Indeed, the failure of the temporal policy he advocated seems to have led Crowley to take orders, and he was ordained deacon by Ridley on the 29th of September 1551. During Mary’s reign he was among the exiles at Frankfort. At Elizabeth’s accession he became a popular preacher, was made archdeacon of Hereford in 1559, and succeeded Paul’s precentor and vicar-general of St Peter’s the Poor in London, and then of St Giles’ without Cripplegate. He refused to minister in the “conjuring garments of popery,” and in 1566 was deprived and imprisoned for resisting the use of the surplice by his choir. He stated his case in “A Brief Discourse against the Outward Apparel and Ministering Garments of the Popish Church,” a tract “memorable,” says Canon Dixon, “as the first distinct utterance of Nonconformity.” He continued to preach occasionally, and in 1576 was presented to the living of St Lawrence Jewry. Nor had he abandoned his connexion with the book trade, and in 1578 he was admitted a freeman of the Stationers’ Company. He died on the 18th of June 1588, and was buried in St Giles’. The most important of his works not hitherto mentioned is his continuation of Languet and Cooper’s Epi tome of Chronicles (1539).

CROWN, an English silver coin of the value of five shillings, hence often used to express the sum of five shillings. It was originally of gold and was first coined in the reign of Henry VIII. Edward VI. introduced silver crowns and half-crowns, and down to the reign of Charles II. crowns and half-crowns and sometimes double crowns were struck both in gold and silver.

In the reign of Edward VI. also was introduced the practice of marking coins and marking them with their current value. The “Oxford crown” struck in the reign of Charles I. was designed by Rawlins (see Numismatics: Medieval). Since the reign of Charles II. the crown has been struck in silver only. At one time during the 19th century it was proposed to abandon the issue of the crown, and from 1861 until 1887 none was struck, but since the second issue in 1887 it has been freely in circulation again.

CROWN and CORONET, an official or symbolical ornament worn on or round the head. The crown (Lat. corona) at first had no regal significance. It was a Garland, or wreath, of leaves or flowers, conferred on the winners in the athletic games. Afterwards it was often made of gold, and among the Romans was bestowed as a recognition of honourable service performed or distinction won, and on occasion it took such a form as to correspond with, or indicate the character of, the service rendered. The corona obdictionalis was formed of grass and flowers plucked on the spot and given to the general who conquered a city. The corona civica, made of oak leaves with acorns, was bestowed on the soldier who in battle saved the life of a Roman citizen. The mural crown (corona muralis) was the decoration of the soldier who was the first to scale the walls of a besieged city, and was usually a circle of gold adorned with a series of turrets. The naval crown (corona navalis), decorated in like manner with a series of miniature prows of ships, was the reward of him who gained a notable victory at sea. These latter crowns form charges in English heraldry (see Heraldry).

Many other forms of crown were used by the Romans, as the conqueror’s triumphal crown of laurel, the myrtle crown, and the convivial, bridial, funeral and other crowns. Some of the emperors wore crowns on occasion, as Caligula and Domitian, at the games, and stellate or spike crowns are depicted on the heads of several of the emperors on their coins, but no idea of imperial sovereignty was indicated thereby. The Roman people, who had accepted imperial rule as a fact, were very jealous of the employment of its emblem on the part of their rulers. That emblem was the diadem, and although the diadem and crown are frequently confused with each other they were quite distinct, and it is well to bear this in mind. The diadem, which was of eastern origin, was a fillet or band of linen or silk, richly embroidered, and was worn tied round the forehead. Selden (Titles of Honour, chap. viii. sect. 8) says that the diadem and crown “have been from ancient times confounded, yet the diadem without a crown was a very different thing from what a crown now is or was, and it was no other than than only a fillet of silk, linen, or some such thing.” It is desirable to remember the distinction, for, although diadem and crown are now used as synonymous terms, the two were originally quite distinct. The confusion between them has, perhaps, come about from the fact that the modern crown seems to be rather an evolution from the diadem than the lineal descendant of the older crowns. The linen or silk diadem was eventually exchanged for a flexible band of gold, which was worn in its place round the forehead. The further development of the crown from this was readily effected by the addition of an upper row of ornament. Thus the medieval and modern crowns may be considered as radiated diadems, and so the diadem and crown have become, as it were, merged in one another.

Among the historical crowns of Europe, the Iron Crown of Lombardy, now preserved at Monza, claims notice. It is a band of iron, enclosed in a circle formed of six plates of gold,
hinged one to the other, and richly jewelled and enamelled. It is regarded with great reverence, owing to a legend that the inner band of iron has been hammered out of one of the nails of the true cross. The crown is so small, the diameter being only 6 in., and the circle only 2½ in. in width, that doubts have been felt as to whether it was originally intended to be worn on the head or was merely meant to be a votive crown. The legend as to the iron being that of one of the nails of the cross is rejected by Muratori and others, and cannot be traced far back. How it arose or how any credence came to be reposed in the legend, it is difficult to surmise. Another historical crown is that of Charlemagne, preserved at Vienna. It is composed of a series of four larger and four smaller plaques of gold, rounded at the tops and set together alternately. The larger plaques are richly ornamented with emeralds and sapphires, and the smaller plaques have each an enamelled figure of Our Lord, David, Solomon, and Hezekiah respectively. A jewelled cross rises from the large front plaque, and an arch bearing the name of the emperor Conrad springs from across the back of this cross to the back of the crown.

At Madrid there is preserved the crown of Svintilla, king of the Visigoths, 621-631. It is a circle of thick gold set with pearls, sapphires and other stones. It has been given as a votive offering at some period to a church, as was often the custom. Attached to its upper rim are the chains whereby to suspend it, and from the lower rim hang letters of red-coloured glass or paste which read +SVINTILANVS REX OFFERET. Two other Visigothic crowns are also preserved with it in the Armeria Real.

In 1584 a most remarkable discovery was made near Toledo, of eight gold crowns of the 7th century, fashioned lavishly with barbaric splendour. They are now in the Cluny Museum at Paris, having been purchased for 4000, the intrinsic value of the gold, without reckoning that of the jewels and precious stones, being not less than £600. The largest and most magnificent is the crown of Recessvinto, king of the Visigoths from 653 to 675. It is composed of a circle of pure gold set with pearls and precious stones in great profusion, which gives it a most sumptuous appearance. It is 9 in. in diameter and more than ½ in. in thickness, the width of the circle being 4 in. It has also been given as a votive offering to a church, and has soon afterwards followed they were buried out of sight for safety, where they were eventually discovered absolutely unharmed centuries afterwards. For a detailed description of these most remarkable crowns the reader must be referred to a paper by the late Mr. Albert Way (Archaeological Journal, xvi. 253). Mr. Way, in the article alluded to, says of the custom of offering crowns to churches that frequent notices of the usage may be found in the lives of the Roman pontiffs by Anastasius: "They are usually described as having been placed over the altar, and in many instances mention is made of jewelled crosses of gold appended within such crowns as an accessory ornament. . . . The crosses suspended in churches suggested doubtless the sumptuous pensile luminaries, frequently designated from a very early period as coronae, in which the form of the royal circlet was preserved in much larger proportions, as exemplified by the remarkable corona still to be seen suspended in the cathedral at Aix-la-Chapelle over the crypt in which the body of Charlemagne was deposited."

Of modern continental crowns the imperial crown of Austria (fig. 4) may be mentioned. It is composed of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lys, and is raised above the circle in the form of a cap which is opened in the middle, so that the lower part is crescent-shaped; across this opening from front to back rises an arched fillet, enriched with pearls and surmounted by an orb, on which is a cross of pearls.

The papal tiara (a Greek word, of Persian origin, for a form of ancient Persian popular head-dress, standing high erect, and worn encircled by a diadem by the kings), the triple crown worn by the popes, has taken various forms since the 9th century. It is important to remember that the tiaras in old Italian pictures are inventions of the artists and not copied from actual examples. In its present shape, dating substantially from the Renaissance, it is a peaked head-covering not unlike a closed mitre (q.v.), round which are placed one above the other three circlets or open crowns. Two bands, or infulae, as they are called, hang from it as in the case of a mitre. The tiara is the crown of the pope as a temporal sovereign (see Tiara).

1 A coloured drawing, done in the first half of the 18th century, of the magnificent tiara made by the celebrated goldsmith, Caradosso, for Julius II., is in the Print-Room, British Museum. It was re-fashioned by Pius VI., but went with other treasure as part of the indemnity to Napoleon. The splendid emerald at the summit, which was engraved with the arms of Gregory XIII., was restored by Napoleon and now adorns another papal tiara at Rome. In this drawing the three crowns (a feature introduced at the beginning of the 14th century) are represented by three bands of X-shaped ornament in enamelled gold.
Pictorial representations in early manuscripts, and the rude effigies on their coins, are not very helpful in deciding as to the form of crown worn by the Anglo-Saxon and Danish kings of England before the Norman Conquest. In some cases it would appear as if the diadem studded with pearls had been worn, and in others something more of the character of a crown. We reach surer ground after the Conquest, for then the great seals, monumental effigies, and coins become more and more serviceable in determining the forms the crown took.

The crown of William the Conqueror and his immediate successors seems to have been a plain circlet with four uprights, which terminated in trefoils (fig. 5), but Henry I. enriched the circlet with pearls or gems (fig. 6), and on his great seal the trefoils have something of the character of fleurs-de-lys. The effigy of Richard I. atFontevrault shows a development of the crown; the trefoil heads are expanded, and are chased and jewelled. The crown of John is shown on his effigy at Worcester, though unfortunately it is rather badly mutilated. It shows, however, that the upper ornament was of fleurons set with jewels. Fig. 7 shows generally this development of the crown in a restored form. The crown on the effigy of Henry III. at Westminster had a beaded row below the circlet, which is narrow and plain, and from it rises a series of plain trefoils with slightly raised points between them. The tomb was opened in 1774, and on the king's head was found an imitation crown of tin or latten gilt, with trefoils rising from its upper edge. This, although only made of base metal for the king's burial, may nevertheless be taken as exhibiting the form of the royal crown at the time, and it may be usefully compared with that on the effigy of the king, which was made in Edward I.'s reign (fig. 8). Edward I. used a crown of very similar design. In the crown of Edward II. we have perhaps the most graceful and elegant of all the forms which the English medieval crown assumed (fig. 9), and it seems to have continued without any marked alteration during the reigns of Edward III. and Richard II.

The crown on the head of the effigy of Henry IV. at Canterbury evidently represents one of great magnificence, both of design and ornament. What is perhaps lost of the grace of form of the crown of Edward II. is made up for by a profusion of ornament and ornamentation unsurpassed at any later period (fig. 10). The circlet is much wider and is richly chased and jewelled, and from it rise eight large leaves, with intervening spaces being filled with fleurs-de-lys of definite outline. It will be noted that this crown is, like its predecessors, what is known as an open crown, without any arches rising from the circlet, but in the accounts of the coronation of Henry IV. by Froissart and Waurin it is distinctly stated that the crown was arched in the form of a cross. This is the earliest mention of an arched crown, which is not represented on the great seal till that of Edward IV. in 1461. The crown, as shown on Henry IV.'s effigy, very probably represents the celebrated "Harry crown" which was afterwards broken up and employed as surety for the loan required by Henry V. when he was about to embark on his expedition to France. Fig. 11 shows the crown of Henry V. The crown of Henry VI. seems to have had three arches, and there is the same number shown on the crown of Henry VII., which ensigns the hawthorn bush badge of that king. The crown of Edward IV. (fig. 12) shows two arches, and a crown similarly arched appears on the great seal of Richard III. Crowns, both open and arched, are represented in sculpture and paintings until the end of the reign of Edward IV., and the royal arms are occasionally ensigns by an open crown as late as the reign of Henry VIII. The crown of Henry VII. on his effigy in Westminster Abbey shows a circlet surmounted by four crosses and four fleurs-de-lys alternately, and has two arches rising from it. A similar crown appears on the great seal of Henry VIII. The crown of Henry VII. (fig. 13), which ensigns the royal arms above the south door of King's College chapel, Cambridge, has the motto of the order of the Garter round the circlet. Fig. 14 shows the form of crown used by Edward VI., but a tendency (not shown in the illustration) began of flattening the arches of the crown, and on some of the coins of Elizabeth the arches are not merely flattened, but are depressed in the centre, much after the character of the arches of the crown on many of the silver coins of the 15th century prior to 1587. The crowns of James I. and Charles I. had four arches, springing from the alternate crosses and fleurs-de-lys of the circlet (fig. 15). The crown which strangely enough surmounts the shield with the arms of the Commonwealth on the coins of Oliver Cromwell (as distinguished from those of the Commonwealth itself, which have no crown) is a royal crown with alternate crosses and fleurs-de-lys round the circlet, and is surmounted by three arches, which, though somewhat flattened, are not bent. On them rests the orb and cross. The crown used by Charles II. (fig. 16) shows the arches depressed in the centre, a feature of the royal crown which seems to have been continued henceforward till 1887, when the pointed form of the arches was resumed, in consonance with an idea that such a form indicated an imperial rather than a regal crown, Queen Victoria having been proclaimed empress of India in 1877. In the foregoing account the changes of the form of the crowns of the kings have been briefly noticed. Those crowns were the personal crowns, worn by the different kings on various state occasions, but they were all crowned before the Commonwealth with the ancient crown of St. Edward, and the queens consort with that of Queen Ethid. There were, in fact, two sets of regalia, the one used for the coronations and kept at Westminster,
circlet with, so far as can be determined, four crosses of pearls or gems on it, and a large cross patee rising from it in front, and arches of jewels or pearls terminating in a large pearl at the top. A valuation of these ancient crowns was made at the time of the Commonwealth prior to their destruction. From this valuation we learn that St Edward's crown was of gold filigree or "wirework" as it is called, and was set with stones, and was valued at £248. Queen Edith's crown was found to be only of silver-gilt, with counterfeit pearls, sapphires and other stones.

![Fig. 16. Recent Forms of the English Crown.](image)

and was only valued at £16. At the Restoration an endeavour was made to reproduce as well as possible the old crowns and regalia according to their ancient form, and a new crown of St Edward was made on the lines of the old one for the coronation of Charles II. The framework of this crown, bereft of its jewels, is in the possession of Lady Amherst of Hackney. The crowns of James II., William III., and Anne generally resembled it in form (fig. 16). The later crowns of the Georges and William IV. are represented in general form in fig. 17. Although the marginal note in the coronation order of Queen Victoria indicates "K. Edward's crown" as that on which the late queen was to be crowned, it was actually the state or imperial crown worn by the sovereign when leaving the church after the ceremony that was used. It had been altered for the coronation, and the arches were formed of oak leaves (fig. 18). Fig. 19 shows Queen Victoria's crown with raised arches and without the inner cap of estate, which since the reign of Henry VII. has been degraded into forming a lining to the crowns of the sovereigns and the coronets of the peers. Fig. 20 shows the coronation crown of King Edward VII. The crown of Scotland, preserved with the Scottish regalia at Edinburgh, is believed to be composed of the original circlet worn by King Robert the Bruce. James V.

![Fig. 17.](image)

![Fig. 18.](image)

Coronation Crowns of Queen Victoria and King Edward VII.

made additions to it in 1535, and in general characteristics it much resembles an English crown of that date.

The kings of arms in England, Scotland and Ireland wear crowns, the ornamentation of which round the upper rim of the circlet is composed of a row of acanthus or oak leaves. Round the circlet is the singularly inappropriate text from Psalm lli., "Miserere mei Deus secundum magnam misericordiam tuam." The form of these crowns seems to have been settled in the reign of Charles II. Before that period they varied at different times, according to representations given of them in grants of arms, &c.

![Fig. 19.](image)

This brings us to the crowns of lesser dignity, known for that reason as coronets, and worn by the five orders of peers.

The use of crowns by dukes originated in 1362, when Edward III. created his sons Lionel and John dukes of Clarence and Lancaster respectively. This was done by investing them with a sword, a cap of maintenance or estate, and with a circlet of gold set with precious stones, which was imposed on the head. Previous to this dukes had been invested at their creation by the girding on of a sword only. In 1387 Richard II. created Richard de Vere marquess of Dublin, and invested him by girding on a sword, and by placing a golden circlet on his head. The golden circlet was confined to dukes and marquesses till 1444, when Henry VI. created Henry Beauchamp, earl of Warwick, premier earl, and the letters patent effecting this concede that the earl and his heirs shall wear a golden circlet on the head on feast days, even in the royal presence. As to the form of these circlets we have no clear knowledge. The dignity of a viscount was first created by Henry VI. in 1439, but nothing is said of any insignia pertaining to that dignity.

![Fig. 20.](image)

![Fig. 21.](image)

Corones of Dukes, Marquesses and Earls.

It is believed that a circlet of gold with an upper rim of pearls was first conferred on a viscount by James I., who conceded it to Robert Cecil, Viscount Cranborne. However, in 1625-1626 it is definitely recorded that the viscounts carried their coronets in their hands in the coronation procession from Westminster Hall to the Abbey church. The use of a coronet by the barons dates from the coronation of Charles II., and by letters patent of the 7th of August 1691 their coronet is described as a circlet of gold with six pearls on it.

At the present day the coronet of a duke (fig. 21) is formed of a circlet of gold, from which rise eight strawberry leaves. The coronet of a marquess (fig. 22) differs from that of a duke in having only four strawberry leaves, the intervening spaces being occupied by four low points which are surmounted by pearls. The coronet of an earl (fig. 23) differs again by having eight tall rays on each of which is set a pearl, the intervening spaces being occupied by strawberry leaves one-fourth of the height of the rays. The coronet of a viscount (fig. 24) has sixteen small pearls fixed to the golden circlet, and the coronet of a baron (fig. 25) has six large pearls similarly arranged.

**CROWN DEBT.** In English law, a debt due to the crown. By various statutes—the first dating from the reign of Henry VIII. (1541)—the crown has priority for its debts before all other creditors. At common law the crown always had a lien on the lands and goods of debtors by record, which could be enforced even when they had passed into the hands of other persons. The difficulty of ascertaining whether lands were subject to a crown lien or not was often very great, and a remedy was provided by the Judgments Act 1839, and the Crown Suits Act
CROWNE—CROWNER 519

1865. Now by the Land Charges Act 1900, no debt due to the crown operates as a charge on land until a writ of execution for the purpose of enforcing it has been registered under the Land Charges Registration and Schedules Act 1888. By the Act of 1541 specialty debts were put practically on the same footing as debts by record. Simple contract debts due to the crown also become specialty debts, and the rights of the crown are enforced by a summary process called an extent (see Writ).

CROWNE, JOHN (d. c. 1703), British dramatist, was a native of Nova Scotia. His father “Colonel” William Crowne, accompanied the earl of Arundel on a diplomatic mission to Vienna in 1637, and wrote an account of his journey. He emigrated to Nova Scotia where he received a grant of land from Cromwell, but the French took possession of his property, and the home government did nothing to uphold his rights. When the son came to England his poverty compelled him to act as gentleman usher to an Independent lady of quality, and his enemies asserted that his father had been an Independent minister. He began his literary career with a romance, Pandion and Amphigenia, or the History of the coy Lady of Thessaly (1665). In 1671 he produced his first acted play, Julian, or the Princess of Poland, which, in spite of its title, no pretensions to rank as an historical drama. The earl of Rochester procured for him, apparently with the sole object of annoying Dryden by infringing on his rights as poet-laureate, a commission to supply a masque for performance at court. Calisto gained him the favour of Charles II., but Rochester proved a fickle patron, and his favour was completely alienated by the success of Crowne’s heroic play in two parts, The Destruction of Jerusalem by Titus Vespasian (1677). This piece contained a thinly disguised satire on the Puritan party in the description of the Pharisees, and about 1683 he produced a distinctly political play, The City Politiques, satirizing the Whig party and containing characters which were readily recognized as portraits of Titus Oates and others. This made him many enemies, and he petitioned the king for a small place that would release him from the necessity of writing for the stage. The king exacted one more comedy, which should, he suggested, he based on the Novatian case of Mortimer. This had already been unsuccessfully adapted, as Crowne discovered later, by Sir Thomas St Serfe, but in Crowne’s hands it developed into Sir Curly “Nice, It Cannot Be (1685), a comedy which kept its place as a stock piece for nearly a century. Unfortunately Charles II. died before the play was completed, and Crowne was disappointed of his reward. He continued to write plays, and it is stated that he was still living in 1703, but nothing is known of his later life.

Crowne was a fertile writer of plays with an historical setting, in which heroic love was, in the fashion of the French romances, the leading motive. The prosaic level of his style saved him as a rule from the rant to be found in so many contemporary heroic plays, but these pieces are of no particular interest. He was much more successful in comedy of the kind that depicts ‘humeurs.’ The History of Charles the Eighth of France, or The Invasion of Naples by Perceval the Great (1676), is the most famous of his plays. In The History of the Corsairs (1673) he attempted an epic poem; The History of Calisia (1674) was supposed to have been written by the earl, a line from this piece, ‘... whilst sporting waves amid the rising sun ...’ was held up to ridicule. The Ambitious Statesman, or The Loyal Favourite (1679), one of the most extravagant of his heroic efforts, is based on the history of Bernard d’Armagnac, Constable of France, after the battle of Agincourt; Thystes, A Tragedy (1681), spares none of the horrors of the Senecan tragedy, although an incongruous love story is worked into the plot. The Passion of Regulus (1679; rep. 1694) and Calligula (1698) complete the list of his tragedies. The Country Wit: A Comedy (acted 1675, pr. 1693), derived in part from Molière’s Le Scélérat, is another example of the successful comic style. The Town Sparks (act. 1689, pr. 1690), perhaps suggested by Molière’s Tartuffe, ridicules the court Catholics, and in Father Fincal caricatures Father Petre; and The Married Beau; or The Complete Interpreter (1684), is based on the Curioso Interpomente in Don Quixote. He also produced a version of Racine’s Andromaque, an adaptation from Shakespeare’s Henry VI., and an unsuccessful comedy, Justice Buz.

CROWN LAND, in the United Kingdom, land belonging to the crown, the hereditary revenues of which were surrendered to parliament in the reign of George III.

In Anglo-Saxon times the property of the king consisted of (a) his private estate, (b) the demesne of the crown, comprising palaces, &c., and (c) rights over the folklan of the kingdom.

By the time of the Norman Conquest the three became merged into the estate of the crown, that is, land annexed to the crown, held by the king as king. The king, also, ceased to hold as a private owner, but he had full power of disposal by grant of the crown lands, which were increased from time to time by confiscation, escheat, forfeiture, &c. The history of the crown lands to the reign of William III. was one of continuous alienation to favourites. Their wholesale distribution by William III. necessitated the intervention of parliament, and in the reign of Queen Anne an act was passed limiting the right of alienation of crown lands to a period of not more than thirty-one years or three lives.

The revenue from the crown lands was also made to constitute part of the civil list. At the beginning of his reign George III. surrendered his interest in the crown lands in return for a civil list income of £120,000. The control and management of the crown lands is now regulated by the Crown Lands Act 1829 and various amending acts. Under these acts their management is entrusted to the commissioners of Woods, Forests and Land Revenues, who have certain statutory powers as to leasing, selling, exchanging, &c.

In theory, also, state lands in the British colonies are supposed to be vested in the crown, and they are called crown lands; actually, however, the various colonial legislatures have full control over them and power of disposal. The term “ crownlands,” in Austria, is applied to the various provinces into which that country is divided. (See Austria.)

CROWN POINT, a village of Essex county, New York, U.S.A., in a township of the same name, about 90 m. N.E. of Albany and about 10 m. N. of Ticonderoga, on the W. shore of Lake Champlain. Pop. of the township (1890) 3135; (1900) 2112; (1905) 1890; (1910) 1659; of the village, about 1000. The village served as the Delware & Hudson Railway and by the Champlain Canal. Among the manufactures are lumber and woodenware. Graphite has been found in the western part of the township, and spar is mined. In 1609 Champlain fought near here the engagement with the Iroquois Indians which marked the beginning of the long enmity between the Five (later Six) Nations and the French. Subsequently Dutch and English traders trafficked in the vicinity, the latter maintaining here for many years a regular trading-post. In 1731 the French built here Fort Frédéric, the first military post at Crown Point, and the place was subsequently for many years of considerable strategic importance, owing to its situation on Lake Champlain, which with Lake George furnished a comparatively easy route from Canada to New York. Twice during the French and Indian War, in 1755 and again in 1776, English and colonial expeditions were sent against it in vain; it remained in French hands until 1759, when, after Lord Jeffrey Amherst’s occupation of Ticonderoga, the garrison joined that of the latter place and retreated to Canada. Crown Point was then occupied by Amherst, who, during the winter of 1776-1777, began the construction, about a quarter of a mile from the old Fort Frédéric, of a large fort, which was garrisoned but was never completed; the ruins of this fort (not of Fort Frédéric) still remain. At the outbreak of the War of Independence, on the 11th of May 1775, the fort, whose garrison then consisted of only a dozen men, was captured by Colonel Seth Warner and a force of “Green Mountain Boys,” sent from Ticonderoga by Ethan Allen; and it remained in American hands save for a brief period in 1777, when it was occupied by a detachment of Burgoyne’s invading army.

CROWTHER, SAMUEL ADJAI (1809–1891), African missionary-bishop, was born at Ochughi in the Yoruba country,1

1 The duchy of Lancaster, which was the private property of Henry IV. before he ascended the throne, was assured to him and his heirs by a special act of parliament. The first year of Henry VII. it was united to the crown, but as a separate property.
CROYDON—CROYDON

West Africa, and was sold into slavery in 1821. Next year he was rescued, with many other captives, by the H.M. ship “Myrmidon,” and was landed at Sierra Leone. Educated there in a missionary school, he was baptized on the 11th of December 1825. In time he became a teacher at Fura Bay, and afterwards an energetic missionary on the Niger. He came to England in 1842, entered the Church Missionary College at Islington, and in June 1843 was ordained by Bishop Blomfield. Returning to Africa, he laboured with great success amongst his own people and afterwards at Abeokuta. Here he devoted himself to the preparation of school-books, and the translation of the Bible and Prayer-Book into Yoruba and other dialects. He also established a trade in cotton, and improved the native agriculture. In 1857 he commenced the third expedition up the Niger, and after labouring with varied success, returned to England and was consecrated, on St Peter’s Day 1864, first bishop of the Niger territories. Before long a commencement was made of the missions to the delta of the Niger, and between 1866 and 1884 congregations of Christians were formed at Bonny, Brass and New Calabar, but the progress made was slow and unsteady. In 1888 the Church Missionary Society turned, and several chiefs embraced Christianity, and on Crowther’s return from another visit to England, the large iron church known as “St Stephen’s cathedral” was opened. Crowther died of paralysis on the 31st of December 1891, having displayed as a missionary for many years untiring industry, great practical wisdom, and deep piety.

CROYDON, a municipal, county and parliamentary borough of Surrey, England, suburb to London, 10 m. S. of London Bridge. Pop. (1891) 102,695; (1901) 133,865. The borough embraces a great residential district. Several railway stations give it communication with all parts of the metropolis, the principal railways serving it being the London, Brighton & South Coast and the South-Eastern & Chatham. It stands near the sources of the river Wandle, under Banstead Downs, and is a place of great antiquity. The original site, farther west than the present town, is mentioned in Domesday Book. The derivation indicated is from the O. Fr. croie dune, chalk hill. The supposition that here was the Roman station of Noviomagus is rejected. The site is remarkable for the number of springs which issue from the soil. One of these, called the “Bourne,” bursts forth a short way above the town at irregular intervals of one to ten years or more; and after running a torrent for two or three months, as quickly vanishes. Until its course was diverted it caused destructive floods. This phenomenon seems to arise from rains which, falling on the chalk hills, sink into the porous soil and reappear after a time from crevices at lower levels. The manor of Croydon was presented by William the Conqueror to Archbishop Lanfranc, who is believed to have founded the archiepiscopal palace there, which was the occasional residence of his successors till about 1570, and of which the chapel and hall remain. Addington Park, 3½ m. from Croydon, was purchased for the residence, in 1807, of the archbishop of Canterbury, but was sold in consequence of Archbishop Temple’s decision to reside at the palace, Canterbury. The neighbouring church, which is Norman and Early English, contains several memorials of archbishops. Near the park a group of tumuli and a circular encirclement are seen. Croydon is a suffragan bishopric in the diocese of Canterbury. The parish church of St John the Baptist appears to have been built in the 14th and 15th centuries, but to have contained remains of an older building. The church was restored or rebuilt in the 16th century, and again restored by Sir Gilbert Scott in 1857-1859. It was destroyed by fire, with the exception of the tower, on the 5th of January 1857, and was at once rebuilt by Scott on the old lines. In 1596 Archbishop Whitgift founded the hospital or almshouse which bears his name, and remains in its picturesque brick buildings surrounding two quadrangles. His grammar school was housed in new buildings in 1871, and is a flourishing day school. The principal public building of Croydon is that erected by the corporation for municipal business; it included court-rooms and the public library. At Addiscombe in the neighbourhood was formerly a mansion dating from 1702, and occupied by the East India Company in 1809 for a Military College, which on the abolition of the Company became the Royal Military College for the East Indian Army, and was closed in 1862. Croydon was formed into a municipal borough in 1883, a parliamentary borough, returning one member, in 1885, and a county borough in 1888. The corporation consists of a mayor, 12 aldermen and 36 councillors. Area, 9012 acres.

CROZAT, PIERRE (1661-1740), French art collector, was born at Toulouse, one of a family who were prominent French financiers and collectors. He became treasurer to the king in Paris, and gradually acquired a magnificent collection of pictures and objets d’art. Between 1729 and 1742 a finely illustrated work was published in two volumes, known as the Cabinet Crozat, including the finest pictures in French collections. Most of his own treasures descended to his nephews, Louis François (d. 1750), Joseph Antoine (d. 1750), and Louis Antoine (d. 1770), and were augmented by them, being dispersed after their deaths; the collection of Louis Antoine Crozat went to St Petersburg.

CROZET ISLANDS, an uninhabited group in the Indian Ocean, lat. 46°-47° S. and 52° E. They are mountainous, with summits from 4000 to 5000 ft. high, and are divided in two main divisions—Penguin or Inaccessible, Hog, Possession and East Islands; and the Twelve Apostles. Like Kerguelen, and other clusters in these southern waters, they appear to be of igneous formation; but owing to the bleak climate and their inaccessible character they are seldom visited, and have never been explored since their discovery in 1772 by Marion-Dufresne, after one of whose officers they are named. Possession, the highest, has a snowy peak said to exceed 5000 ft. Hog Island takes its name from the animals which were here let loose by an English captain many years ago, but have since disappeared. Rabbits burrow in the heaps of scoria on the slopes of the mountains.

CROZIER, WILLIAM (1855- ), American artist and inventor, born at Carrollton, Carroll county, Ohio, on the 19th of February 1853, was the son of Robert Crozier (1827-1895), chief justice of Kansas in 1865-1866, and a United States senator from that state from December 1873 to February 1874. He graduated at West Point in 1876, was appointed a 2nd lieutenant in the 4th Artillery, and served on the Western frontier for three years against the Sioux and Bannock Indians. From 1879 to 1884 he was instructor in mathematics at West Point, and was superintendent of the Watertown (Massachusetts) Arsenal from 1884 to 1887. In 1888 he was sent by the war department to study recent developments in artillery in Europe, and upon his return he was placed in full charge of the construction of gun carriages for the army, and with General Adelbert R. Buffington (1837- ), the chief of ordnance, he invented the Buffington-Crozier disappearing gun carriage (1896). He also invented a wire-wound gun, and perfected many appliances connected with heavy and field ordnance. In 1890 he attained the rank of captain. During the Spanish-American War he was inspector-general for the Atlantic and Gulf coast defences. In 1899 he was one of the American delegates to the Peace Conference at the Hague. He later served in the Philippine Islands on the staffs of Generals John C. Bates and Theodore Schwab, and in 1900 was chief of ordnance on the staff of General A. R. Chaffee during the Philippine Relief Expedition. In November 1901 he was appointed brigadier-general and succeeded General Buf- fington as chief of ordnance of the United States army. His Notes on the Construction of Ordnance, published by the war department, are used as text-books in the schools for officers, and he is also the author of other important publications on military subjects.

CROZIER, or pastoral staff, one of the insignia of a bishop, and probably derived from the litus of the Roman augurs. It is crook-headed, and borne by bishops and archbishops alike (see Pastoral Staff). The word "crozier" or "crozier" represents the O. Fr. croisier, Med. Lat. crozierius, the bearer of the episcopal crook (Med. Lat. croceo, croceia, &c., Fr. croie). The English representative of croieo was cross, later cruzeo, which, becoming confused with "cross" (q.v.), was replaced by "crozier-
CRUCIAL—CRUCIFERAЕ

521

staff" or "crozier's staff," and then, at the beginning of the 16th century, by "crozier" (see J. T. Taylor, *Archaeologia*, li., "On the Use of the Terms Crozier, Pastoral Staff and Cross").

CRUCIAL (from Lat. crus, a cross), that which has the form of a cross, as the "crucial ligaments" of the knee-joint, which cross each other, connecting the femur and the tibia. From Francis Bacon's expression *instantia crucis* (taken, as he says, from the finger-post or *crux* at cross-roads) for a phenomenon which decides between two causes which have each similar analogies in its favour, comes the use of "crucial" for that which decides between two alternatives, hence, generally, as a synonym for "critical." The word is also used, with a reference to the use of a "crucible," of something which tests and tries.

CRUCIFERAЕ, or Crucifer family, a natural order of flowering plants, which derives its name from the cruciform arrangement of the four petals of the flower. It is an order of herbaceous plants, many of which, such as wallflower, stock, mustard, cabbage, radish and others, are well-known garden or field-plants. Many of the plants are annuals; among these are some of the commonest weeds of cultivation, shepherd's purse (*Capsella Bursa-pastoris*), charlock (*Brassica Sinapis*), and such common plants as hedge mustard (*Sisymbrium officinale*), Jack-by-the-hedge (*S. Alliaria* or *Alliaria officinalis*). Others are biennials producing a number of leaves on a very short stem in the first year, and in the second sending up a flowering shoot at the expense of the nourishment stored in the thick tap-root during the previous season. Under cultivation this root becomes much enlarged, as in turnip, swede and others. Wallflower (*Cheiranthus Cheiri*) (fig. 1) is a perennial. The leaves when borne on an elongated stem are arranged alternately and have no stipules. The flowers are arranged in racemes without bracts; during the life of the flower its stalk continues to grow so that the open flowers of an inflorescence stand on a level (that is, are corymbose). The flowers are regular, with four free sepals arranged in two pairs at right angles, four petals arranged crosswise in one series, and two sets of stamens, an outer with two members and an inner with four, in two pairs placed in the middle line of the flower and at right angles to the outer series. The four inner stamens are longer than the outer; and the stamens are hence collectively described as tetradynamous. The pistil, which is above the rest of the members of the flower, consists of two carpels joined at their edges to form the ovary, which becomes two-celled by subsequent ingrowth of a septum from these united edges; a row of ovolves springs from each edge. The fruit is a pod or siluca splitting by two valves from below upwards and leaving the placentas with the seeds attached to the *replum* or framework of the septum. The seeds are filled with the large embryo, the two cotyledons of which are variously folded. In germination the cotyledons come above ground and form the first green leaves of the plant.

Pollination is effected by aid of insects. The petals are generally white or yellow, more rarely lilac or some other colour, and between the bases of the stamens are honey-glands. Some or all of the anthers become twisted so that insects in probing for honey will touch the anthers with one side of their head and the capitulate stigma with the other. Owing, however, to the close proximity of stigma and anthers, very slight irregularity in the movements of the visiting insect will cause self-pollination, which may also occur by the dropping of pollen from the anthers of the larger stamens on to the stigma.

Cruciferaе is a large order containing nearly 200 genera and about 1200 species. It has a world-wide distribution, but finds its chief development in the temperate and frigid zones, especially of the northern hemisphere, and as Alpine plants. In the subdivision of the order into tribes use is made of differences in the form of the fruit and the manner of folding of the embryo. When the fruit is several times longer than broad it is known as a silica, as in stock or wallflower; when about as long as broad, a silicula, as in shepherd's purse.

![Diagram of Cruciferaе](image)

**Fig. 1.** Wallflower (*Cheiranthus Cheiri*), reduced. 1, Flower in vertical section. 2, Horizontal plan of arrangement of flower in *Barbarae*.

**Fig. 5.** Seeds of Cruciferaе cut across to show the radicle and cotyledons. (After Baillon.) A, *Cheiranthus Cheiri*. B, *Sisymbrium Alliaria*.
The order is well represented in Britain—among others by *Nasturtium* (N. officinale, water-cress), *Arabis* (rock-cress), *Cardamine* (bitter-cress), *Styrumbrum* (hedge mustard, &c.; *S. Iris* is London rocket, so-called because it sprang up after the fire of 1666), *Brassica* (cabbage and mustard), *Podolaxis* (rocket), *Cochlearia* (scruvy-grass), *Capsella* (shepherd’s purslane), *Lepidium* (cress), *Thlospi* (penny-cress), *Cabell* (sea rocket), *Raphanus* (radish), and others. Of economic importance are species of *Brassica*, including mustard (*B. nigra*), white mustard, used when young in salads (*B. alba*), cabbage (*B. oleracea*), and its numerous forms derived from *B. oleracea*, turnip (*B. campestris*), and *B. raphanistrum* (*B. Nigra*). *Raphanus* sativus (radish), *Cochlearia Armoracia* (horseradish), *Nasturtium officinale* (water-cress), *Lepidium sativum* (garden cress). *Isatis* affords a blue dye, woad. Many of the genera are known as ornamental garden plants; such are *Cheiranthus* (wallflower), *Mathiola* (stock), *Iberis* (candy-tuft), *Alyssum* ( Alison), *Hesperis* (dame’s violet), *Lunaria* (honesty) (fig. 6), *Aubrietia* and others.

**CRUDEN, ALEXANDER** (1701–1770), author of the well-known concordance (q.v.) to the English Bible, was born at Aberdeen, on the 31st of May 1701. He was educated at the grammar school, Aberdeen, and studied at Marischal College, intending to enter the ministry. He took the degree of master of arts, but soon after began to show signs of insanity owing to a disappointment in love. After a term of confinement he recovered and removed to London, where he was employed as a private tutor to the son of a country squire living in the East Hall, St. Peter’s gate, and also held a similar post at Ware. Years afterwards, in an application for the title of bookseller to the queen, he stated that he had been for some years correttor for the press in Wild Court. This probably refers to this time. In 1726 he was employed by the 10th earl of Derby as a reader and secretary, but was discharged on the 7th of July for his ignorance of French pronunciation. He then lodged in a house in Soho frequented exclusively by Frenchmen, and took lessons in the language in the hope of getting back his post with the earl, but when he went to Knowsley in Lancashire, the earl would not see him. He returned to London and opened a bookseller’s shop in the Royal Exchange. In April 1735 he obtained the title of bookseller to the queen by recommendation of the lord mayor and most of the Whig aldermen. The post was an unremunerative sinecure. In 1737 he finished his concordance, which, he says, was the work of several years. It was presented to the queen on the 3rd of November 1737, a fortnight before her death.

Although Cruden’s Biblical labours have made his name a household word among English-speaking people, he was disappointed in his hopes of immediate profit, and his mind again became unhinged. In spite of his earnest and self-denying piety, and his exceptional intellectual powers, he developed idiosyncrasies, and his life was marred by a harmless but ridiculous egotism, which so nearly bordered on insanity that his friends sometimes thought it necessary to have him confined. He paid unwelcome addresses to a widow, and was confined in a madhouse in Bethnal Green. On his release he published a pamphlet dedicated to Lord H. (probably Harrington, secretary of state) entitled *The London Citizen exceedingly injured, or a British Inquisition Displayed*. He also published an account of his trial, dedicated to the king. In December 1740 he writes to Sir H. Sloane saying he has been employed since July as Latin usher in a boarding-school at Enfield. He then found work as a proof-reader, and several editions of Greek and Latin classicals are said to have owed their accuracy to his care. He superintended the printing of one of Matthew Henry’s commentaries, and in 1750 printed a small *Compendium of the Holy Bible* (an abstract of the contents of each chapter), and also reprinted a larger edition of the *Concordance*.

About this time he adopted the title of “Alexander the Corrector,” and assumed the office of correcting the morals of the nation, especially with regard to swearing and Sunday observance. For this office he believed himself divinely commissioned, but he petitioned parliament for a formal appointment in this capacity. In April 1755 he printed a letter to the speaker and other members of the House of Commons, and about the same time an “Address to the King and Parliament.” He was in the habit of carrying a sponge, with which he effaced all inscriptions which he thought contrary to good morals. In September 1755, through being involved in a street brawl, he was confined in an asylum in Chelsea for seventeen days at the instance of his sister, Mrs. Wild. He brought an unsuccessful action against his frieund and co-worker, and they should go into confinement as an atonement.

He published an account of this second restraint in “*The Adventures of Alexander the Corrector*.” He made attempts to present to the king in person an account of his trial, and to obtain the honour of knighthood, one of his predicted honours. In 1754 he was nominated as parliamentary candidate for the city of London, but did not go to the poll. In 1755 he paid unwelcome addresses to the daughter of Sir Thomas Abney, of Newington (1640–1722), and then published his letters and the history of his repulse in the third part of his “Adventures.” In June and July 1755 he visited Oxford and Cambridge. He was treated with the respect due to his learning by officials and residents in both universities, but experienced some boisterous fooling at the hands of the undergraduates. At Cambridge he was knighted with mock ceremonies. There he appointed “deputy correctors” to represent him in the university. He also visited Eton, Windsor, Tonbridge and Westminster schools, where he appointed four boys to be his deputies. (An *Admonition to Correcters* was published, and *Correcters from all parts of Great Britain to Dr. Cox Macro*, in the British Museum.)

The Corrector’s Earnest Address to the Inhabitants of Great Britain, published in 1756, was occasioned by the earthquake at Lisbon. In 1762 he saved an ignorant seaman, Richard Potter, from the gallows, and in 1763 published a pamphlet recording the history of the case. Against John Wilkes, whom he hated, he wrote a small pamphlet, and used to delete with his sponge the number 45 wherever he found it, this being the offensive number of the North Briton. In 1769 he lectured in Aberdeen as “Corrector,” and distributed copies of the fourth commandment and various religious tracts. The wit that made his eccentricities palatable is illustrated by the story of how he gave to a conceited young minister whose appearance displeased him *A Mother’s Catechism dedicated to the young and ignorant*. The Scripture Dictionary, compiled about this time, was printed in Aberdeen in two volumes shortly after his death. Alexander Chalmers, who in his boyhood heard Cruden lecture in Aberdeen and wrote his biography, says that a verbal index to Milton, which accompanied the edition of Camus *Necropoly*, was dedicated by Cruden to the people of Billinge. In 1760, was Cruden’s.

The second edition of the Bible *Concordance* was published in 1761, and presented to the king in person on the 21st of December. The third appeared in 1769. Both contain a pleasing portrait of the author. He is said to have gained £300 by these two editions. He returned to London from Aberdeen, and died suddenly while praying in his lodgings in Camden Passage, Islington, on the 1st of November 1770. He was buried in the ground of a Protestant dissenting congregation in Dead Man’s Place, Southwark. He bequeathed a portion of his savings for a £5 bursary at Aberdeen, which preserves his name on the list of benefactors of the university.

(D. MN.)
CRUDEN—CRUIKSHANK

CRUDEN, a village and parish on the E. coast of Aberdeen- shire, Scotland. Pop. of parish (1901) 3444. It is situated at 1 mile from the bay, 203 m. N.N.E. of Aberdeen by the Great North of Scotland railway company’s branch line from Ellon to Boddam. The golf-course of 18 holes is one of the best in Scotland, and there is a sandy beach, with good bathing. There is some good fishing at Port Erroll, also called Ward of Crudens. Prehistoric remains have been found in the parish, and near Ardendraught, not far from the shore, Malcolm II. is said to have defeated Canute in 1014. The Water of Crudens, which rises a few miles to the west, flows through the village into the North Sea. Slains Castle, a seat of the earl of Erroll, lies to the north of Crudens, but must not be confounded with the old castle of Slains, about 5 m. to the south-west, near the point where, according to tradition, the “St Catherine” of the Spanish Armada founded in 1588. The Bullers of Buchan are within 2 m. walk of Crudens.

Cruelty (through the O. Fr. cruălité, mod. cruelité, from the Lat. crudelitas), the intentional infliction of pain or suffering. It is only necessary to deal here with the legal relations involved. Statutory provisions for the prevention of cruelty to those who are unable to protect themselves has been particularly marked in the 19th century. The increase of legislation for the protection of children, lunatics and animals is a proof of the growing humanitarianism of the age. There was at one time a tendency among jurists to question whether, for instance, the prevention of cruelty to animals was not a recognition that a certain quasi-right in animals, or whether it was merely that such exhibitions as bull- and bear-baiting, cock-fights, &c., were demoralizing to the public generally. The true fact seems to be that the first introduction of such legislation was undoubtedly due to the desire for the promotion of humanity, but that the principle, for the recognition of which the time was not yet ripe, had to be excused in the eyes of the public by the plea that cruelty had a demoralizing effect upon spectators (see A. V. Dicey, Law and Opinion in England, p. 188; T. E. Holland, Jurisprudence, 10th ed., p. 372).

Cruelty to Animals.—The English common law has never taken cognizance of the commission of acts of cruelty upon animals, and direct legislation upon the subject, dating from the 19th century, was due in a great measure to public agitation, supported by the Royal Society for the Prevention of Cruelty to Animals (founded in 1824). Various acts were passed in 1822 (known as Martin’s Act), 1835 and 1837, and these were amended and consolidated by the Cruelty to Animals Acts 1849 and 1854, which, with the Wild Animals in Captivity Protection Act 1900, are the main acts upon the subject. There are also, in addition, many other acts that impose certain liabilities in respect of animals and indirectly prevent cruelty. The Cruelty to Animals Acts 1849 and 1854 render liable to prosecution and fine practically any act of cruelty to an animal; such acts as dabbing a cock, cropping the ears of a dog or disfiguring cattle, are offences. The latter practice, however, is allowed both in Scotland and Ireland, the courts having held that the advantage to be obtained from disfiguring cattle outweighs the operation. The word “animal” is defined as meaning “any domestic animal” of whatever kind or species, and whether a quadruped or not. The act of 1849 also forbids bull- and bear- baiting, or fighting between any kinds of animals; requires the provision of food and water to animals impounded; lays down regulations as to the treatment of animals sent for slaughter, and imposes a penalty for improperly conveying animals. The Wild Animals in Captivity Protection Act 1900 extends to wild animals in captivity that protection which the acts of 1849 and 1854 conferred on domestic animals, making exception of any act done or any omission in the preparation of animals for the food of man or for sport. The word “animal” in the act includes bird, beast, fish, or reptile. The Dogs Act 1865 rendered owners of dogs liable for injuries to cattle and sheep; the Dogs Act 1906 extended the owner’s liability for injury done to any cattle by a dog, and further, where a dog is proved to have injured cattle or chased sheep it may be treated as a dangerous dog and must be kept under proper control or be destroyed. The Drugging of Animals Act 1876 imposes a penalty on giving poisonous drugs to any domestic animal unlawfully. The Cruelty to Animals Act 1876 was passed for the purpose of regulating the practice of vivisection (q.v.). The Ground Game Act 1880, prohibits night shooting, or the use of spring traps above ground or poison. The Injured Animals Act 1907 enables police constables to cause any animal when mortally or seriously injured to be slaughtered. The Diseases of Animals Act 1894 and orders under it are for the purpose of securing animals from unnecessary suffering, as well as from disease. Finally, the Wild Birds Protection Acts 1880 to 1904, with various game acts (see Game Laws), extend the protection of the law to wild birds. The acts establish a close time for wild birds and impose penalties for shooting or taking them within that time; prohibit the exposing or offering for sale within certain dates any wild bird recently killed or taken unless bought or received from some person residing out of the United Kingdom; the taking or destroying of wild birds’ eggs, the setting of pole traps, and the taking of a wild bird by means of a hook or other similar instrument.

For the law relating to the prevention of cruelty to children see CHILDREN, LAW RELATING TO; for cruelty in the sense of such conduct as entitles a husband or wife to judicial separation see DIVORCE.

CRUIKSHANK, GEORGE (1792–1878), English artist, caricaturist and illustrator, was born in London on the 27th of September 1792. By natural disposition and collateral circumstances he may be accepted as the type of the born humoristic artist predestined for this special form of art. His grandfather had taken up the arts, and his father, Isaac Cruikshank, followed the painter’s profession. Amidst these surroundings the children were born and brought up, their first playthings the materials of the arts their father practised. George followed the family traditions with amazing facility, easily surpassing his compères as an etcher. When the father died, about 1817, George, still in his teens, was already a successful and popular artist. All his acquisitions were native gifts, and of home-growth; outside training, or the serious apprenticeship to art, were dispensed with, under the necessity of working for immediate profit. This lack of academic training the artist at times found cause to regret, and at some intervals he made exertions to cultivate the knowledge obtainable by studying from the antique and drawing from life at the schools. From boyhood he was accustomed to turn his artistic talents to ready account, disposing of designs and etchings to the printellers, and helping his father in forwarding his plates. Before he was twenty his spirited style and talent had secured popular recognition; the contemporary of Gillray, Rowlandson, Alken, Heath, Dighton, and the established caricaturists of that generation, he developed great proficiency as an etcher. Gillray’s matured and trained skill had some influence upon his executive powers, and when the older caricaturist passed away in 1815, George Cruikshank had already acquired his place as a satirist. Prolific and dexterous beyond his competitors, for a generation he delineated Tories, Whigs and Radicals with fine impartiality. Satirical capital came to him from every public event,—wars abroad, the enemies of England (for he was always fervidly patriotic), the camp, the court, the senate, the Church; low life, high life; the humours of the people, the follies of the great. In this wonderful gallery the student may grasp the popular side of most questions which for the time being engaged public attention. George Cruikshank’s technical and manipulative skill as an etcher was such that Ruskin and the best judges have placed his productions in the foremost rank; in this respect his works have been compared favourably with the masterpieces of etching. He died at 263 Hampstead Road on the 1st of February 1878. His remains rest in St Paul’s cathedral.

A vast number of Cruikshank’s spirited cartoons were published as separate caricatures, all coloured by hand; others formed series, or were contributed to satirical magazines, the Satirist, Town Talk, The Scourge (1811–1816) and the like.
CRUNDEN—CRUSADES

ephemeral publications. In conjunction with William Hone’s 
scatrical tracts, G. Cruikshank produced political satires to 
illustrate the works of facetiae and miscellanies, like The Political 
House that Jack Built (1819).

Of a more genially humoristic order are his well-known book 
illustrations, now so deservedly esteemed for their inimitable fun 
and frolic, among other qualities, such as the weird and terrible, 
in which he excelled. Early in this series came The Humorist 
(1810-1821) and Life in Paris (1822). The well-known series of 
Life in London, conjointly produced by the brothers I. R. and 
G. Cruikshank, has enjoyed a prolonged reputation, and is still 
sought after by collectors. Grimm’s Collection of German Popular 
Stories (1824-1826), in two series, with 22 inimitable etchings, 
are in themselves sufficient to account for G. Cruikshank’s 
reputation. To the first fourteen volumes (1837-1843) of 
Bentley’s Miscellany Cruikshank contributed 120 of his best 
plates, etched on steel, including the famous illustrations to 
Oliver Twist, Jack Sheppard, Guy Fawkes and The Ingoldsby 
Legends. For W. Harrison Ainsworth, Cruikshank illustrated 
Rookwood (1836) and The Tower of London (1840); the first six 
Volumes of Ainsworth’s Magazine (1822-1844) were illustrated 
by him with several of his finest suites of etchings. For C. 
Lever’s Arthur O’Leary he supplied 10 full-page etchings 
(1844), and 20 spirited graphic etchings for Maxwell’s lurid 
History of the Irish Rebellion in 1798 (1845). Of his own 
speculations, mention must be made of George Cruikshank’s 
Omnibus (1841) and George Cruikshank’s Table Book (1845), 
as well as his Comic Almanack (1835-1853). The Life of Sir John 
Palstaff contained 20 full-page etchings (1857-1858).

These are a few leading items amongst the thousands of illus-
trations emanating from that fertile imagination. As an enthusi-
astic teetotal advocate, G. Cruikshank produced a long series of 
illustrations and pictorial pamphlets and tracts; the best known of 
these are The Bottle, 8 plates (1847), with its sequel, The Drunkard’s 
Children, 8 plates (1848), with the ambitious work, The Worship of Bacchus, published by sub-
scription after the artist’s oil painting, now in the National 
Gallery, London, to which it was presented by his numerous 
admirers.

See Cruikshank’s Water-Colours, with introduction by Joseph 
Grego (London, 1893). (J. Go.)*

CRUNDEN, JOHN (d. 1828), English architectural and 
and mobiliary designer. Most of his early inspiration was drawn 
from Chippendale and his school, but he fell later under the 
influence of a bastard classicism. He produced a very large 
number of designs which were published in numerous volumes; 
among the most ambitious were ornamental centres for ceilings 
in which he introduced cupids with bows and arrows, Fame 
sounding her trumpet, and such like motives. Sport and natural 
history supplied him with many other themes, and one of his 
ceilings is a hunting scene representing a “kill.” His principal 
works were Designs for Ceilings; Convenient and Ornamental 
Architecture; The Carpenter’s Companion for Chinese Railings, 
Gates, &c. (1770); The Joiner and Cabinet-maker’s Darling, or 
Staty Designs for Gothic, Chinese, Mosaic and Ornamental 
Frets (1792); and The China Plate Maker’s Assistant (1776).

Most of his work was either absurd or valueless.

CRUSADES, the name given to the series of wars for 
the delivering the Holy Land from the Mahomedans, so-called from 
the cross worn as a badge by the crusaders. By analogy the term 
“cruse” is also given to any campaign undertaken in the 
same spirit.

1. The Meaning of the Crusades.—The Crusades may be 
regarded partly as the decumanus fictus in the surge of religious 
revival, which had begun in western Europe during the 10th, 
and had mounted high during the 11th century; partly as a 
chapter, and a most important chapter, in the history of the 
interaction of East and West. Contemporaries regarded them 
in the former of these two aspects, as “holy wars” and “pil-
gims’ progress” towards Christ’s Sepulchre; the reflective 
eye of history must perhaps regard them more exclusively from 
the latter point of view. Considered as holy wars the Crusades 
must be interpreted by the ideas of an age which was dominated 
by the spirit of otherworldliness, and accordingly ruled by 
the clerical power which represented the other-world. They are 
a novum salutis genus—a new path to Heaven, to tread which 
“for full and complete satisfaction” pro omni poenitentia 
and gave “forgiveness of sins” (peccaminum remissio); they, 
are again, the “foreign policy” of the papacy, directing its 
faithful subjects to the great war of Christianity against 
the infidel. As such a novum salutis genus, the Crusades connect 

1Fulcher of Chartres, 1, 1. For what follows, with regard to 
the Church’s conversion of guerra into the Holy War, cf. especially the 
passage—Procedent contra infidles ad pugnam jam incipi dignam 
qui abusive privatum certamen contra fides conuenseabant 
distendere quondam.
a feudal society; it was also able to pursue the object of its own immediate policy, and to attempt the universal diffusion of Christianity, even at the edge of the sword, over the whole of the known world.

Thus was renewed, on a greater scale, that ancient feud of East and West, which has never died. For a thousand years, from the Hegira in 622 to the siege of Vienna in 1683, the peril of a Mahommedan conquest of Europe was almost continually present. From this point of view, the Crusades appear as a reaction of the West against the pressure of the East—a reaction which carried the West into the East, and founded a Latin and Christian kingdom on the shores of the East. They protected Europe from the new revival of Mahommedanism under the Turks; they gave it a time of rest in which the Western civilization of the middle ages developed. But the relation of East and West during the Crusades was not merely hostile or negative. The Latin kingdom of Jerusalem was the meeting-place of two civilizations: on its soil the East learned from the West, and perhaps still more—the West learned from the East. The culture developed in the West during the 13th century was not only permitted to develop by the protection of the Crusades, it grew upon materials which the Crusades enabled it to import from the East. Yet the debt of Europe to the Crusades in this last respect has perhaps been unduly emphasized. Sicily was still more the meeting-place of East and West than the kingdom of Jerusalem; and the Arabs of Spain gave more to the culture of Europe than the Arabs of Syria.

2. Historical Causes of the Crusades.—Within fifteen years of the Hegira Jerusalem fell before the arms of Omar (637), and it continued to remain in the hands of Mahomedan rulers till the end of the First Crusade. For centuries, however, a lively intercourse was maintained between the Latin Church in Jerusalem, which the clemency of the Arab conquerors tolerated, and the Christians of the West. Charlemagne in particular was charmed with Jerusalem: the patriarch sent him the keys of the city and a standard in 800; and in 897 Harun al-Rashid recognized this symbolic cession, and acknowledged Charlemagne as protector of Jerusalem and owner of the church of the Sepulchre. Charlemagne founded a hospital and a library in the Holy City; and later, when he made him the first of crusaders and the conqueror of the Holy Land, was not without some basis of fact. The connexion lasted during the 9th century; kings like Alfred of England and Louis of Germany sent contributions to Jerusalem, while the Church of Jerusalem acquired estates in the West. During the 10th century this intercourse still continued; but in the 11th century interruptions began to come. The fanaticism of the caliph Hakim destroyed the church of the Sepulchre and ended the Frankish protectorate (1010); and the patronage of the Holy Places, a source of strife between the Greek and the Latin Churches as late as the beginning of the Crimean War, passed to the Byzantine empire in 1021. This latter change in itself made pilgrimages from the West increasingly difficult: the Byzantines, especially after the schism of 1054, did not seek to smooth the way of the pilgrim, and Victor II. had to complain to the empress Theodora of the exactions practised by her officials. But still worse for the Latins was the capture of Jerusalem by the Seljukian Turks in 1071. Without being intolerant, the Turks were a rougher and ruder race than the Arabs of Egypt whom they displaced; while the wars between the Fatimites of Egypt and the Abbasids of Bagdad, whose cause was represented by the Seljuks, made Syria (one of the natural battle-grounds of history) into a troubled and unquiet region. The native Christians suffered; the pilgrims of the West found their way made still more difficult, and that at a time when greater numbers than ever were thronging to the East. Western Christians could not but feel hampered and checked in their natural movement towards the fountain-head of their religion, and it was natural that they should ultimately endeavour to clear the way. In much the same way, at a later date and in a lesser sphere, the closing of the trade-routes by the advance of the Ottoman Turks led traders to endeavour to find new channels, and issued in the rounding of the Cape of Good Hope and the discovery of America. Nor, indeed, must it be forgotten that the search for new and more direct connexions with the routes of Oriental trade is one of the motives underlying the Crusades themselves, and leading to what may be called the 13th-century discovery of Asia.

It was thus natural, for these reasons, that the conquest of the Holy Land should gradually become an object for the ambition of Western Christianity—an object which the papacy, eager to realize its dream of a universal Church subject to its sway, would naturally cherish and attempt to advance. Two causes combined to make this object still more natural and more definite. On the one hand, the reconquest of lost territories from the Mahomedans by Christian powers had been proceeding steadily for more than a hundred years before the First Crusade; on the other hand, the position of the Eastern empire after 1071 was a clear and definite summons to the Christian West, and proved, in the event, the immediate occasion of the holy war. After a desperate recovery of the territories lost to Mahommedanism in the East had been begun by emperors like Nicephorus Phocas and John Zimisces: they had pushed their conquests, if only for a time, as far as Antioch and Edessa, and the temporary occupation of Jerusalem is attributed to the East Roman arms. At the opposite end of the Mediterranean, in Spain, the Omayyad caliphate was warring to its fall: the long Spanish crusade against the Moor had begun; and in 1018 Roger de Toeni was already leading Normans into Catalonia to the aid of the native Spaniards. In the centre of the Mediterranean the fight between Christian and Mahomedan had been long, but was finally inclining in favour of the Christian. The Arabs had begun the conquest of Sicily from the East Roman empire in 827, and they had attacked the mainland of Italy as early as 846. The popes had put themselves at the head of Italian resistance: in 845 Leo IV. is already promising a sure and certain hope of salvation to those who die in defence of the cross; and by 916, with the capture of the Arab fortress at Garigliano, Italy was safe. Then came the reconquest of the Mediterranean islands near Italy. The Pisans conquered Sardinia at the instigation of Benedict VIII. about 1016; and, in a thirty years’ war which lasted from 1060 to 1090, the Normans, under a banner blessed by Pope Alexander II., wrested Sicily from the Arabs. The Norman conquest of Sicily may with justice be called a crusade before the Crusades; and it cannot but have given some impulse to that later attempt to wrest Syria from the Mahommedans, in which the virtual leader was Bohemund, a scion of the same house which had conquered Sicily. But while the Christians of the West were thus winning fresh ground from the Mahommedans, in the course of the 11th century, the East Roman empire had now to bear the brunt of a Mahommedan revival under the Seljuks—a revival which, while it crushed for a time the Greeks, only acted as a new incentive to the Latins to carry their arms to the East. The Seljukian Turks, first the mercenaries and then the masters of the caliph, had given new life to the decadent caliphate of Bagdad. Under the rule of their sultans, who assumed the role of mayors of the palace in Bagdad about the middle of the 11th century, they pushed westwards towards the caliphate of Egypt and the East Roman empire. While they wrested Jerusalem from the former (1071), in the same year they inflicted a crushing defeat on the Eastern emperor at Manzikert. The result of the defeat was the loss of almost the whole of Asia Minor; the dominions of the Turks extended to the sea of Marmora. An appeal for assistance, such as was often to be heard again in succeeding centuries, was sent by Michael VII. of Constantinople to Gregory VII. in 1073. Gregory listened to the appeal; he projected—not, indeed, as has often been said, a crusade, but a great expedition, which should recover the natural path to the holy land for those who died in the pursuit of it.  

1 Tradition credits a pope still earlier than Gregory VII. with the idea of a crusade. Silvester II. is said to have preached a general expedition for the recovery of Jerusalem; and the same preaching is attributed to Sergius IV. in 1011. But the supposed letter of Silvester is a later forger; and in 1000 the way of the Christian to Jerusalem was still free and open.
Asia Minor for the Eastern empire, in return for a union of the Eastern and the Western Church. In 1074 Gregory actually assembled a considerable army; but his disagreement with Robert Guiscard, followed by the outbreak of the war of investitures, hindered the realization of his plans, and the only result was a precedent and a suggestion for the events of 1095.

The appeal of Michael VII. was re-echoed by Alexius Comnenus himself. Brave and sanguine as he was, he could hardly cope at one and the same time with the hostility of the Normans on the west, of the Petchenegs (Patzinaks) on the north, and of the Seljuk on the east and south. Already in 1087 and 1088 he had appealed to Baldwin of Flanders, verbally and by letter,¹ for troops; and Baldwin had answered the appeal. The same appeal was made, more than once, to Urban II.; and the answer was the First Crusade. The First Crusade was not, indeed, what Alexius had asked or expected to receive. He had appealed for reinforcements to recover Asia Minor; he received hundreds of thousands of troops, independent of him, and intending to conquer Jerusalem for themselves, though they might incidentally recover Asia Minor for the Eastern empire on their way. Alexius may almost be compared to a magician, who has uttered a spell, and from which a ministering spirit is surrounded on the instant by legions of demons. In truth the appeal of Alexius had set free forces in the West which were independent of, and even ultimately hostile to, the interests of the Eastern empire.

The primary force, which thus transmuted an appeal for reinforcements into a holy war for the conquest of Palestine, was the Church. The creative thought of the middle ages is clerical thought. It is the Church which creates the Carolingian empire, because the clergy thinks in terms of empire. It is the Church which creates the First Crusade, because the clergy believes in penitentiary pilgrimages, and the war against the Seljuk can be turned into a pilgrimage to the Sepulchre; because, again, it wishes to direct the fighting instinct of the laity, and the consecrating name of Jerusalem provides an unimpeachable channel; above all, because the papacy desires a perfect and universal Church, and a perfect and universal Church must rule in the Holy Land. But it would be a mistake to regard the Crusades (as it would be a mistake to regard the Carolingian empire) as a pure creation of the Church, or as merely due to the policy of a theocracy directing men to the holy war which is the only war possible for a theocracy. It would be almost true, though only half the truth, to say that the clergy gave the name of Crusade to sanctify interests and ambitions which, while set on other ends than those of the Church, happened to coincide in their choice of means. There was, for instance, the ambition of the adventurer prince, the younger son, eager to carve a principality in the far East, of whom Bohemund is the type; there was the interest of Italian towns, anxious to acquire the products of the East more directly and cheaply, by erecting their own emporia in the eastern Mediterranean. The former was the driving force which made the First Crusade successful, where later Crusades, without its stimulus, for the most part failed; the latter was the one staunch ally which alone enabled Baldwin I. and Baldwin II. to create the kingdom of Jerusalem. So far as the Crusades led to permanent material results in the East, they do so in virtue of the natural and normal enthusiasm might of itself have achieved little or nothing; enthusiasm caught and guided by the astute Norman, and the less astute Venetian or Genoese, could not but achieve tangible results. The principle or the emporium, it is true, would supply motives to the prince and the merchant only; and it may be urged that to the mass of the crusaders the religious motive was all in all. In this way we may return to the view that the First Crusade, at any rate, was un faiet ecclésiastique.

It is indeed true that to thousands the hope of acquiring spiritual merit must have been a great motive; it is also true, as the records of crusading sermons show, that there was a strong element of "revivalism" in the Crusades, and that thousands were hurried into taking the cross by a gust of that uncontrollable enthusiasm which is excited by revivalist meetings to-day. But it must also be admitted that there were motives of this world to attract the masses to the Crusades. Famine and pestilence at home drove men to emigrate hopefully to the golden East. In 1094 there was pestilence from Flanders to Bohemia: in 1095 there was famine in Lorraine. Francigenus occidentalis facile persuasuri poterat sua rura reliquer; nam Gallias per annos aliquot nunc seditio civilis, nunc fames, nunc mortalitatis nimis afflexerat.² No wonder that a stream of emigration set towards the East, such as would in modern times flow towards a newly discovered gold-field—a stream carrying in its turbulent waters much refuse, tramps and bankrupts, camp-followers and hucksters, fugitive monks and escaped villeins, and marked by the same motley grouping, the same fever of life, the same alternations of affluence and beggary, which mark the rush for a gold-field to-day.

Such were the forces set in movement by Urban II., when, after holding a synod at Piacenza (March, 1095), and receiving there fresh appeals from Alexius, he moved to Clermont, in the S.E. of France, and there on the 26th of November delivered the great speech which was followed by the First Crusade. In this speech he appealed, indeed, for help for the Greeks, auxilii ... saepe acclamati indigis (Fulcher i. c. i.); but the gist of his speech was the need of Jerusalem. Let the truce of God be observed at home; and let the arms of Christians be directed to the winning of Jerusalem in an expedition which should count for full and complete penance. Like Gregory, Urban had thus sought for aid for the Eastern empire; unlike Gregory, who had only mentioned the Holy Sepulchre in a single letter, and then casually, he had struck the note of Jerusalem. The instant cries of Deus vult which answered the note showed that Urban had struck a chord. Thousands at once took the cross; the first was Bishop Adhemar of Puy, whom Urban named his legate, and made leader of the First Crusade (for the holy war, according to Urban's original conception, must needs be led by a clerk). Fixing the 15th of August 1096 as the time for the departure of the crusaders, and Constantinople as the general rendezvous, Urban returned from France to Italy. It is noticeable that it was on French soil that the seed had been sown.³ Preached on French soil by a pope of French descent, the Crusades began—and they continued—as essentially a French (or perhaps better Norman-French) enterprise; and the kingdom which they established in the East was essentially a French kingdom, in its speech and its customs, its virtues and its vices. It was natural that France should be the home of the Crusades.

She was already the home of the Clinkiac movement, the centre from which radiated the truce of God, the chosen place of chivalry; she could supply a host of feudal nobles, somewhat loosely tied to their place in society, and ready to break loose for a great enterprise; she had suffered from battle and murder, pestilence and famine, from which any escape was welcome. The Crusades were above all a movement for the energy and the intimate appeal. They appealed to the old Norse instinct for wandering—an instinct which, as it had long before sent the Norseman eastward to find his El Dorado of Mickle barg, could now find a natural outlet in the expedition to Jerusalem: they appealed to the Norman religiosity, which had made them a people of pilgrims, the allies of the papacy, and, in England and Sicily, crusaders before the Crusades: finally, they appealed to that desire to gain fresh territory; upon which Malaterra remarks as characteristic of Norman princes.⁴ No wonder, then, that

¹ The comte de Riant impugned the authenticity of Alexius' letter to the count of Flanders. It is very probable that the versions of this letter which we possess, and which are to be found only in later writings like Guibert de Nogent, are apocryphal; Alexius can hardly have held out the bait of the beauty of Greek women, or have written that he preferred to fall under the yoke of the Latins rather than that of the Turks. But it is also probable that these apocryphal versions are based on a genuine original.

² Eckehard, Chronica, p. 213.

³ The Chanson de Roland, which cannot be posterior to the First Crusade—for the poem never alludes to it—already contains the idea of the Holy War against Islam. The idea of the crusade had thus already ripened in French poetry, before Urban preached his sermon.

⁴ Book i. c. iii. (in Muratori, S.R.I., v. 550).
the crusading armies were recruited in France, or that they were led by men of the stock of the d’Hautpillys. Meanwhile newly-conquered England had its own problems to solve; and Germany, torn by civil war, and not naturally quick to kindle, could only deride the “delirium” of the crusader.

3. Course of the First Crusade.—The First Crusade falls naturally into two parts. One of these may be called the Crusade of the people: the other may be termed the Crusade of the princes. Of these the people’s Crusade—prior in order of time, if only secondary in point of importance—may naturally be studied first. The sermon of Urban II. at Clermont became the staple for wandering preachers, among whom Peter the Hermit distinguished himself by his fiery zeal. Riding on an ass from place to place through France and along the Rhine, he carried away by his eloquence thousands of the poor. Some three or four months before the term fixed by Urban II., in April and May 1096, five divisions of paupers already had collected. Three of these, led by Fulcher of Orleans, Gottschalk and William the Carpenter respectively, failed to reach even Constantinople. The armies of Fulcher and Gottschalk were destroyed by the Hungarians in just revenge for their excesses (June); the third, after joining in a wild Judenheitse in the towns of the valley of the Rhine, during which some 10,000 Jews perished as the first-fruits of crusading zeal, was scattered to the wind (July). Two other divisions, however, had reached Constantinople in safety. The first of these, under Walter the Penniless, passed through Hungary in May, and reached Constantinople, where it halted to wait for the Hermit, in the middle of July. The second, led by Peter himself, passed safely through Hungary, but suffered severely in Bulgaria, and only attained Constantinople with sadly diminished numbers at the end of July. These two divisions (which in spite of good treatment by Alexius began to commit excesses against the Greeks) united and crossed the Bosphorus in August, Peter himself remaining in Constantinople. By the end of October they had perished utterly at the hands of the Seljuks, a heap of whitening bones also remained to testify to the later crusaders, when they passed in the spring of 1097, of the fate of the people’s Crusade.

Meanwhile the knights had already begun to assemble in March 1096. In small bands, and by divers ways, they streamed gradually southward and eastward, in a steady flow, through 1096. But three large divisions, under three considerable leaders, were pre-eminent among the rest. Godfrey of Bouillon, with his brother Baldwin, led the two other divisions of Lorrainian nobility, “the road of Charles the Great,” through Hungary, to Constantinople, where he arrived on the 23rd of December. Raymond of Toulouse (the first prince to join the crusading movement) along with Bishop Adhemar, the papal commissary, led the Provençals down the coast of Illyria, and then due east to Constantinople, arriving towards the end of April 1097. Bohemund of Taranto, the destined leader of the crusade, with his nephew Tancred, led a fine force of Normans by sea to Durazzo, and thence by land to Constantinople, which he reached about the same time as Raymond. To the same great rendezvous other leaders also gathered, some of higher rank than Godfrey or Raymond or Bohemund, but none destined to exercise an equal influence on the fate of the Crusade. Hugh of Vermandois, younger brother of Philip I. of France, had reached Constantinople in November 1096, in a species of honourable captivity, and had done Alexius homage; Robert of Normandy and Stephen of Blois, to whom Urban II. had given St Peter’s banner at Lucca, only arrived—the last of the crusaders—in May 1097 (their original companion in arms, Count Robert of Flanders, having left them to winter at Bari, and crossed to Constantinople before the end of 1096).

Thus was gathered at Constantinople, in the spring of 1097, a great host, which Fulcher computes at 600,000 men (i.e. iv.), Urban II. at 300,000, and which was probably some 150,000 strong. Before we follow this host into Asia, we may pause to inquire into the various factors which would determine its course, or condition its activity. On the Western side, and among the crusaders themselves, there were two factors of importance, already mentioned above—the aims of the adventurer prince, and the interests of the Italian merchant; while on the Eastern side there are again two—the policy of the Greeks, and the condition of the Mahommedan East. We have already seen that among the princes who joined the First Crusade there were some who were rather politiques than devots, and who aimed at the acquisition of temporal profit as well as of spiritual merit. Of these the type—and, it may almost be said, the inspirer of the rest—was Bohemund. From the first he had an Eastern principality in his mind’s eye; and if we may judge from the follower of Bohemund who wrote the Gesta Francorum, there had already been some talk at Constantinople of Antioch as the seat of this principality. Bohemund’s policy seems to have inspired Baldwin, the brother of Godfrey of Bouillon to emulation; on the one hand he strove to thwart the endeavours of Tancred, the nephew of Bohemund, to begin the foundation of the Eastern principality for his uncle by conquering Cilicia, and, on the other, he founded a principality in Edessa. Raymond of Provence, this last of the great politiques of the First Crusade, was, like Baldwin, envious of Bohemund; and jealously drove him first to atten pt to wrest Antioch from Bohemund, and then to found a principality of Tripoli to the south of Antioch, which would check the growth of his power. The political motives of these three princes, and the interaction of their different policies, was thus a great factor in determining the course and the results of the First Crusade. The influence of the Italian towns did not make itself greatly felt till after the end of the First Crusade, when it made possible the foundation of a kingdom in Jerusalem, in addition to the three principalities established by Bohemund, Baldwin and Raymond; but during the course of the Crusade itself the Italian ships which hugged the shores of Syria were able to supply the crusaders with provisions and munition of war, and to render help in the sieges of Antioch and Jerusalem. Sea-power had thus some influence in determining the victory of the crusaders.

In the East the conditions were, on the whole, favourable to the crusaders. The one difficulty—and it was serious—was the slow advance of Alexius. Confronted by the crusaders where he had asked for auxiliaries, Alexius took two alternative policies presented to his choice. He might, in the first place, have frankly admitted that the crusaders were independent allies, and treating them as equals, he might have waged war in concert with them, and divided the conquests achieved in the war. A boundary line might have been drawn somewhere to the N.W. of Antioch; and the crusaders might have been left to acquire what they could to the south and east of that line. Unhappily, clinging to the conviction that all the lands which the crusaders would traverse were the “lost provinces” of his empire, he induced the crusaders to do him homage, so that, whatever they conquered, they would conquer in his name, and whatever they held, they would hold by his grant and as his vassals. Thus Hugh of Vermandois became the man of Alexius in November 1096; Godfrey of Bouillon was induced, not without difficulty, to do homage in January 1097; and in April and May the other leaders, including Bohemund and the obstinate Raymond himself, followed his example. The policy of Alexius was destined to produce evil results, both for the Eastern empire and for the crusading movement. The West had already greatly its grievances against the East: the Greek emperors had taken advantage of their protectorate of the Holy Places to levy charges.

1 Ekkehard, Chronica, 214.
2 Later legend ascribed the origin of the First Crusade to the preaching of Peter the Hermit. The legend has been followed by modern historians: but in point of fact Peter is a figure of secondary importance. (See Peter the Hermit.)
on the pilgrims, against which the Papacy had already been forced to remonstrate; nor were the Italian towns, with the exception of favoured Venice, disposed to be friendly to the great monopolist city of Constantinople. The old dissension of the Eastern and Western Churches had blazed out afresh in 1054; and the policy of Alexius only added new rancours to an old grudge, which culminated in the Latin conquest of Constantinople in 1204. On the other hand, the success of the crusading movement was imperilled, both now and afterwards, by the jealousy of the Comneni. Always hostile to the principality, which Bohemund established in spite of his oath, they helped by their hostility to cause the loss of Edessa in 1144, and thus to hasten the disintegration of the Latin kingdom of Jerusalem. Yet one must remember, in justice to Alexius, the gravity of the problem by which he was confronted; nor was the conduct of the crusaders themselves such that he could readily make them his brethren in arms.

The condition of Asia Minor and Syria in 1097 was almost altogether such as to favour the success of the crusaders. The Seljuk sultans had only achieved a military occupation of the country which they had conquered. There were Seljukian garrisons in towns like Nicaea and Antioch, ready to offer an obstinate resistance to the crusaders; and here and there: in the country there were Seljukian armies, either cantonned or nomadic. But the inhabitants of the towns were often hostile to the garrisons, and over wide tracts of country there were no forces at all. Accordingly, when the crusaders had captured the town at Nicaea, and defeated the Seljukian field-army at Dorylaeum their way lay clear before them through Asia Minor. Not only so, but they could count, at the very least, on a benevolent neutrality from the native population; while from the Armenian principalities in the S.E. of Asia Minor, which survived unsubdued in the general deluge of Seljukian conquest, they could expect active assistance (the hope of which will explain the north-easterly line of march which they followed after leaving Heraclea). But the purely military character of the Seljukian occupation helped the crusaders in yet another way. Strong generals were needed in the separate divisions of the empire, and these, as has always been the case in Eastern empires, made themselves independent in their spheres of command, because there was no organization to keep them together under a single control. On the death of Malik Shah, the last of the great Seljuk emperors (1092), the empire dissolved. A new sultan, Barki-yarq or Barkiarok, ruled in Bagdad (1094-1104); but in Asia Minor Kilij Arslan held sway as the independent sultan of Konia (Iconium), while the whole of Syria was also practically independent. Not only was Syria thus weakened by being detached from the body of the Seljuk empire; it was divided by disensions within, and assailed by the Fatimite caliph of Egypt from without. In 1093 two brothers, Ridwan and Dekak, ruled in Aleppo and Damascus respectively; but they were at war with one another, and Yagi-sian, the ruler of Antioch, was a party to their disensions. Ridwan and Yagi-sian were only stirred to action by Damascus, which, in the autumn of the crusaders, which led the latter to throw himself hastily into Antioch, in the autumn of 1097. Meanwhile the Fatimites were not slow to take advantage of these disensions. A great religious division divided the Fatimite caliph of Cairo, the head of the Shiite sect, from the Abbasid caliph of Bagdad, who was the head of the Sunnites. The difference may be compared to the dissension between the Greek and the Latin Churches; but it had perhaps more of the nature of a political difference. In any case, it hampered the Mahommedans as much as the jealousy between Alexius and the Latins hampered the progress of the Crusade. The crusading princes were well enough aware of the gulf which divided the caliph of Cairo from the Sunnite princes of Syria; and they sought to employ to put themselves into connexion with him, hoping by his aid to gain Jerusalem (which was then ruled for the Turks by Sokman, the son of the amir Ortok).1 But the caliph preferred to act for

---

1 Thus already on the First Crusade the path of negotiation is attempted simultaneously with the Holy War. On the Third himself, and took advantage of the wars of the Syrian princes, and of the terror inspired by the advance of the crusaders to conquer Jerusalem (August 1098). But though the leaders of the First Crusade did not succeed in utilizing the disensions of the Mahommedans as fully as they desired, it still remains true that these disensions very largely explain their success. It was the dissolution of the Syrian amirs, and the division between the Abbasids and the Fatimites, that made possible the conquest of the Holy City and the foundation of the kingdom of Jerusalem. When a power arose in Mosul, about 1130, which was able to unify Syria—when, again, in the hands of Saladin, unified Syria was in turn united to Egypt—the cause of Latin Christianity in the East was doomed.

We are now in a position to follow the history of the First Crusade. By the beginning of May 1097 the crusaders were crossing the Bosporus, and entering the dominions of Kilij Arslan. Their first operation was the siege of Nicaea, defended by a Seljuk garrison, and eventually captured, with the aid of Alexius, after a month's siege (June 18). Alexius took possession of the town; and though he rewarded the crusading princes richly, some discontent was excited by his action. After the capture of Nicaea, the field-army of Kilij Arslan had to be met. In a long and obstinate encounter, it was defeated at Dorylaeum (July 7), and this march and counter-march un molested in a south-easterly direction to Heraclea. There Tancred, followed by Baldwin, turned into Cilicia, and began to take possession of the Cilician towns, and especially of Tarsus—thus beginning, it would seem, the creation of the Norman principality of Antioch. The main army turned to the N.E., in the direction of Caesarea (in order to bring itself into touch with the Armenian princes of this district), and then marched southward again to Antioch. At Marash, half way between Caesarea and Antioch, Baldwin, who had meanwhile wrested Tarsus from Tancred, rejoined the ranks; but he soon left the main body again, and struck eastward towards Edessa, to found a principality there. At the end of October the crusaders came into position before Antioch, which was held by Yagi-sian, and began the siege of the city, which lasted from October 21, 1097, to June 3, 1098. The great figure in the siege was naturally Bohemund (who had also been the hero of Dorylaeum). He repelled attempts at relief made by Dekak (Dec. 31, 1097) and Ridwan (Feb. 9, 1098); he put the besiegers in touch with the Genoese ships lying in the harbor of St Simeon, outside the port of Antioch (March 1098) —a move which at once secured him the want of provisions from which the crusaders suffered, and secured materials for the building of castles, with which Bohemund sought—to overawe the besieged city. But it was finally by the treachery of one of Yagi-sian's commanders, the amir Firuz, that Bohemund was able to effect its capture. The other leaders had, however, to promise him possession of the city, before he would bring his negotiations with Firuz to a conclusion; and the matter was so long protracted that an army of relief under Kerbogha of Mosul was only at a distance of three days' march, when the city was taken (June 3, 1098). The besiegers were no sooner in the city, than they were besieged in their turn by Kerbogha; and the twenty-five days which followed were the worst period of stress and strain which the crusaders had to encounter. Under the pressure of this strain the "spiritualistic" phenomena began to appear. It was in the ranks of the Provençals, where the religiosity of Count Raymond seems to have extended to his followers, that these phenomena appeared; and they culminated in the discovery of the Holy Lance (March 26). This had a second great effect, the excitement which it gave enabled the crusaders to meet and defeat Crusade, and above all on the Sixth, this path was still more seriously attempted. It is interesting, too, to notice the part which the laity already plays in directing the course of the Crusade. From the first the Crusade, however clerical in its conception, was largely secular in its conduct; and thus, somewhat paradoxically, a religious enterprise aided the growth of the secular motive, and contributed to the escape of the laity from that tendency towards a papal theocracy, which was evident in the pontificate of Gregory VII.
CRUSADES

529

Kerboga in the open (June 28), but not before many of their number, including even Count Stephen of Blois, had deserted and fled.

With the discovery of the Lance, which became as it were a Provençal asset, Count Raymond assumes a new importance. Mingled with the religiosity of his nature there was much obstinacy and self-seekimg; and when Kerboga was finally repelled, he began to dispute the possession of Antioch with Bohemund, pleading in excuse his oath to Alexis. The struggle lasted for some months, and helped to delay the further progress of the crusaders. Raymond, indeed, left Antioch in November, and moved S.E. to Marra; but his men still held two positions in Antioch, from which they were not dislodged by Bohemund till January 1099. Expelled from Antioch, the obstinate Raymond endeavoured to recompense himself in the south (where indeed he subsequently created the county of Tripoli); and from February to May 1099 he occupied himself with the siege of Arca, to the N.E. of Tripoli. It was during the siege of Arca that Peter Bartholomew, to whom the vision of the Holy Lance had first appeared, was subjected, with no definite result, to the ordeal of fire— the hard-headed Normans doubting the genuineness of the wonder of any Provençal vision, the more wild, as in this case, it turned to the political advantage of the Provençals.

The siege was long protracted; the mass of the pilgrims were anxious to proceed to Jerusalem, and, as the altered tone of the author of the Gesta sufficiently indicates, thoroughly weary of the obstinate political bickerings of Raymond and Bohemund. Here Godfrey of Bouillon finally came to the front, and placing himself at the head of the discontented pilgrims, he forced Raymond to accept the offers of the amir of Tripoli, to desist from the siege, and to march to Jerusalem (in the middle of May 1099). Bohemund remained in Antioch: the other leaders pressed forward, and following the coast route, arrived before Jerusalem in the beginning of June. After a little more than a month's siege, the city was finally captured (July 15). The slaughter was terrible; the blood of the conquered ran down the streets, until men splashed in blood as they rode. At nightfall, "sobbing for excess of joy," the crusaders came to the Sepulchre from their treading of the winepress, and put their blood-stained hands together in prayer. So, on that day of July, the First Crusade came to an end.

It remained to determine the future government of Jerusalem; and here the eternal problem of the relations of Church and State emerged. It might seem natural that the Holy City, conquered in a holy war by an army of which the pope had made a churchman, Bishop Adhemar, the leader, should be left to the government of the Church. But Adhemar had died in August 1098 (whence, in large part, the confusion and bickerings which followed in the end of 1098 and the beginning of 1099); nor were there any churchmen left of sufficient dignity or weight to secure the triumph of the ecclesiastical cause. In the meeting of the crusaders on the 22nd of July, some few voices were raised in support of the view that a "spiritual vicar" should first be chosen in the place of the late patriarch of Jerusalem (who had just died in Cyprus), before the election of any lay ruler was taken in hand. But the voices were not heard; and the princes proceeded at once to elect a lay ruler. Raymond of Provençals refused to accept their nomination, nominally on the pious ground that he did not wish to reign where Christ had suffered on the cross; though one may suspect that the establishment of a principality in Tripoli—in which he had been interrupted by the pressure of the pilgrims—was still the first object of his ambition. The refusal of Raymond meant the choice of Godfrey of Bouillon, who had, as we have seen, become prominent since the siege of Arca; and Godfrey accordingly became—not king, but "advocate of the Holy Sepulchre," while a few days afterwards Arnulf, the chaplain of Robert of Normandy, and one of the sceptics in the matter of the Holy Lance, became "vicar" of the vacant patriarchate. Godfrey's first business was to repel an Egyptian attack, which he accomplished successfully at Ascalon, with the aid of the other crusaders (August 12). At the end of August the other crusaders returned, and Godfrey was left with a small army of 2000 men, and the support of Tancred, now prince of Galilee, to rule in some four isolated districts—Jaffa, Jerusalem, Ramla and Haifa. At the end of the year came Bohemund and Godfrey's brother Baldwin (now count of Edessa) on a pilgrimage to Jerusalem. The result of Bohemund's visit was new trouble for Godfrey. Bohemund procured the election of Dagobert, the archbishop of Pisa, to the vacant patriarchate, disliking Arnulf, and perhaps hoping to find in the new patriarch a political supporter. Bohemund and Godfrey together became Dagobert's vassals; and in the spring Godfrey even seems to have entered into an agreement with the patriarch to cede Jerusalem and Jaffa into his hands, in the event of acquiring other lands or towns, especially Cairo, or dying without direct heirs. When Godfrey died in July 1100 (after successful forays against the Mahomedans which took him as far as Damascas), it might seem as if a theocracy were after all to be established in Jerusalem, in spite of the events of 1099.

4. The Latin Kingdom of Jerusalem under the First Three Kings, 1099-1143.—The theocracy, however, was not destined to be established. Godfrey had died without direct heirs; but in far Edessa there was his brother Baldwin, ready to take his place. Dagobert had at first consented to the dying Godfrey's wish that Baldwin should be his successor; but when Godfrey died he saw an opportunity too precious to be missed, and opposed Baldwin, counting on the support of Bohemund, to whom he sent an appeal for assistance. But a party in Jerusalem, headed by the late "vicar" Arnulf, opposed itself to the hierarchical pretensions of Dagobert and the Norman influence by which they were backed; and this party, representing the Lotharingian laity, carried the day. Baldwin was summoned from Edessa; and when he arrived, towards the end of the year, he was crowned king by Dagobert himself. Thus was founded, on Christmas day 1100, the Latin kingdom of Jerusalem; and thus was the possibility of a theocracy finally annihilated. A feudal kingdom of Frankish seigneurs was to be planted on the soil of Palestine, instead of a dominium temporale of the patriarch like that of the pope in central Italy. Nor were any great difficulties with the Church to hamper the growth of this kingdom. For two years, indeed, a struggle raged between Baldwin I. and Dagobert: Baldwin accused the patriarch of treachery, and attempted to force him to contribute to the defence of the kingdom. But in 1102 the struggle ceased with the deposition of the patriarch and the victory of the king; and though it was renewed for a time by the patriarch Stephen in the reign of Baldwin II. (1128-1130), the new struggle was of short duration, and was soon ended by Stephen's death.

The establishment of a kingdom in Jerusalem in 1100 was a blow, not only to the Church but to the Normans of Antioch. At the end of 1099 any contemporary observer must have believed that the capital of Latin Christianity in the East was destined to be Antioch. Antioch lay in one of the most fertile regions of the East; Bohemund was almost, if not quite, the greatest genius of his generation; and when he visited Jerusalem at the end of 1099, he led an army of 25,000 men—and those men, at any rate in large part, Normans. What could Godfrey offer such a force? Yet the principalcy of Godfrey was destined to higher things than that of Bohemund. Jerusalem, like Rome, had the shadow of a mighty name to lend prestige to its ruler; and as residence in Rome was one great reason of the strength of the medieval papacy, so was

1 Before he left, Raymond had played in Jerusalem the same part of dog in the manger which he had also played at Antioch, and had given Godfrey considerable trouble. See the articles, GODFREY OF BOUILLON, and RAYMOND OF TOLEDO.

2 For an account of the kings of Jerusalem see the articles on the five BALDWINs, on the two AMALRICs, on Fulk and John of Brienne and on the LUSIGNANS (family).

3 The genuineness of the letter (on which, by the way, depends the story of Godfrey's agreement with Dagobert) has been impeached by Prutz and Kugler, and doubted by Röhrich. It is accepted by von Sybel and Hagenmeyer.
residence in Jerusalem a reason for the ultimate supremacy of the Lotharingian kings. Jerusalem attracted the flow of pilgrims from the Holy Land far more than ever could; and though the great majority of the pilgrims were only birds of passage, there were always many who stayed in the East. There was thus a steady immigration into the kingdom, to strengthen its armies and recruit with new blood the vigour of its inhabitants. Still more important perhaps was the fact that the ports of the kingdom attracted the Italian towns; and it was therefore to the kingdom that they lent the strength of their armies and the skill of their siege-artillery—in return, it is true, for concessions of privileges so considerable as to weaken the resources of the kingdom they helped to create. While Jerusalem possessed these advantages, Antioch was not without its defects. It had to meet—or perhaps it would be more true to say, it brought upon itself—the hostility of strong Mahommedan powers in the vicinity. As early as 1100 Bohemund was captured in battle by Danishmend of Sivas; and it was his captivity, depriving the patriarch as it did of Norman assistance, which allowed the unopposed accession of Baldwin I. Again, in 1104, the Normans, while attempting to capture Jerusalem, which was taken by the Latins in 1101, had a heavy defeat at the river of Kelion near Rakka; and this defeat may be said to have been fatal to the chance of a great Norman principality. But the hostility of Alexius, aided and abetted by the jealousy of Raymund of Toulouse, was almost equally fatal. Alexius claimed Antioch: was it not the old possession of his empire, and had not Bohemund done him homage? Raymund was ready to defend the claims of Alexius; was not Bohemund a successful rival? Thus it came about that Alexius and Raymond became allies; and by the aid of Alexius Raymond established, from 1102 onwards, the principality which, with the capture of Tripoli in 1109, became the principality of Tripoli, and barred the advance of Antioch to the south. Meanwhile the armies of Alexius not only prevented any further advance to the N.W., but conquered the Cilician towns (1104). No wonder that Bohemund flung himself in revenge on the Eastern empire in 1108—only, however, to meet with a humiliating defeat at Durazzo.

Thus it was that Baldwin waxed while Bohemund waned. The growth of Baldwin's kingdom, as it was suggested above, owed more to the interests of Italian traders than to its crusading zeal. In 1100, indeed, it might appear that a new Crusade from the West, which the capture of Antioch in 1098 had begun, and the conquest of Jerusalem in 1099 had finally set in motion, was destined to achieve great things, for the nascent kingdom. Thousands had joined this new Crusade, which should deal the final blow to Mahommedanism: among the rest came the first of the troubadours, William IX., Count of Poitiers, to gather copy for his muse, and even some, like Stephen of Blois and Hugh of Vermandois, who had joined the First Crusade, but had failed to reach Jerusalem. The new crusaders cherished high plans; they would free Bohemund and capture Bagdad. But each of the three sections of their army was routed in turn in Asia Minor by the princes of Sivas, Aleppo and Harran, in the middle of 1101; and only a few escaped to report the crushing disaster. Baldwin I. had thus no assistance to expect from the West, save that of the Italian towns. From an early date Italian ships had followed the crusaders. There were Genoese ships in St Simeon's harbour in the spring of 1098 and at Jaffa in 1099; in 1100, Dogenet, the archbishop of Pisa, led a fleet from his city to the Holy Land; and in 1100 there came to Jaffa a Venetian fleet of 200 sail, whose leaders promised Venetian assistance in return for freedom from tolls and a third of each town they helped to conquer. But it was the Genoese who helped Baldwin I. most. The Venetians already enjoyed, since 1080, a favoured position in Constantinople, and had the less reason to find a new emporium in the East; while Pisa connected itself, through Dagobert, with Antioch, rather than with Jerusalem, and was further, in 1111, invested by Alexius with privileges which made an outlet in the Holy Land no longer necessary. But the Genoese, who had helped with provisions and siege-tackle in the capture of Antioch and of Jerusalem, had both a stronger claim on the crusaders, and a greater interest in acquiring an eastern emporium. An alliance was accordingly struck in 1101 (Fulcher ii. c. vii.), by which the Genoese promised their assistance, in return for a third of all booty, a quarter in each town captured, and a grant of freedom from tolls. In this way Baldwin I. was able to take Arsuf and Caesarea in 1101 and Acre in 1104. But Genoese aid was given to others beside Baldwin (it enabled Raymund to capture Byblus in 1104, and his successor, William, to win Tripoli in 1109); while, on the other hand, Baldwin enjoyed other aids besides that of the Genoese. In 1110, for example, he was enabled to capture Sidon by the aid of Sigurd of Norway, the Jorsalafari, who came to the Holy Land with a fleet of 55 ships, starting in 1107, and in three years' 'wandering,' after the old Norse fashion, fighting the Moors in Spain, and fraternizing with the Normans in the Balearic Islands, brought the great city of Barcelona, and gave her aid to the kings of Jerusalem. Irritated by the concessions made by Alexius to the Pisans in 1111, and furious at the revocation of her own privileges by John Comnenus in 1118, the republic naturally sought a new outlet in the Holy Land. A Venetian fleet of 120 sail came in 1123, and after aiding in the repulse of an attack, which the Egyptians had taken advantage of Baldwin II.'s captivity to deliver, they helped the regent Eustace to capture Tyre (1124), in return for considerable privileges—freedom from tolls throughout the kingdom, a quarter in Jerusalem, baths and ovens in Acre, and in Tyre one-third of the city and its suburbs, with their own court of justice and their own church. After thus gaining a new footing in Tyre, the Venetians could afford to attack the islands of the Aegean as they returned, in revenge for the loss of their privileges in Constantinople; but the hostility between Venice and the Eastern empire was soon afterwards appeased, when John Comnenus restored the old privileges of the Venetians. The Venetians, however, maintained their position in Palestine; and their quarters remained, along with those of the Genoese, as privileged commercial franchises in an otherwise feudal state.

In this way the kingdom of Jerusalem expanded until it came to embrace a territory stretching along the coast from Beirut (captured in 1100) to el-Arish on the confines of Egypt—a territory whose strength lay not in Judaea, like the ancient kingdom of David, but, somewhat paradoxically (though commercial motives explain the paradox), in Phoenicia and the land of the Philistines. With all its length, the territory had but little breadth: towards the north it was bounded by the amirate of Damascus; in the centre, it spread little, if at all, beyond the Jordan; and it was only in the south that it had any real extension. Here there were two considerable annexes. To the south of the Dead Sea stretched a tongue of land, reaching to Aila, at the head of the eastern arm of the Red Sea. This had been won by Baldwin I., by way of revenge for the attacks of the Egyptians on his kingdom; and here, as early as 1116, he had built the fort of Monrel, half way between Aila and the Dead Sea. To the east of the Dead Sea, again, lay a second strip of territory, in which the great fortress was Krak (Kerak) of the Desert, planted somewhere about 1140 by the royal butler, Paganus, in the reign of Fulk of Jerusalem. These extensions in the south and east had also, it is easy to see, a commercial motive. They gave the kingdom a connexion of its own with the Red Sea and its shipping; and they enabled the Franks to

1 Yet the north always continued to be more populous than the south; and the Latins maintained themselves in Antioch and Tripoli a century after the loss of Jerusalem. The land was richer in the north: it was protected by its connexion with Cyprus and Armenia: it was more remote from Egypt—the basis of Mahomedan power from the reign of Saladin onwards.

2 Pisa naturally connected itself with Antioch, because Antioch was hostile to Constantinople, and Pisa cherished the same hostility, since Alexius I. had in 1080 given preferential treatment to Venice, the enemy of Pisa.

3 This is the year in which the kingdom may be regarded as definitely founded. The period of conquest practically ends at this date, though isolated gains were afterwards made. The year 1110 is additionally important by reason of the accession of Maudud al Mosul, which marks the beginning of a Moslem reaction.
control the routes of the caravans, especially the route from Damascus to Egypt and the Red Sea. Thus, it would appear, the whole of the expansion of the Latin kingdom (which may be said to have attained its height in 1131, at the death of Baldwin II.) may be shown to have been dictated, at any rate in large part, by economic motives; and thus, too, it would seem that two of the most powerful motives which sway the mind of man—the religious motive and the desire for gain—conspired to elevate the kingdom of Jerusalem (at once the country of Christ, and a natural centre of trade) to a position of supremacy in Latin Syria. During this process of growth the kingdom stood in relation to two sects of powers—the three Frankish principalities in northern Syria, and the Mahommedan powers both of the Euphrates and the Nile—whose action affected its growth and character.

Of the three Frankish principalities, Edessa, founded in 1098 by Baldwin I. himself, was a natural fief of Jerusalem. Baldwin de Burgh, the future Baldwin II., ruled in Edessa as the vassal of Baldwin I. from 1100 to 1118; and thereafter the county was held in succession by the two Joscelins of Tell-basht until the capture of Edessa by Zengi in 1144. Zengi, moving eastwards from the Euphrates, at once in close contact with the Armenians, and in proximity to the great route of trade which came up the Euphrates to Rakka, and thence diverged to Antioch and Damascus, the county of Edessa had an eventful if brief life. The county of Tripoli, the second of these principalities, had also come under the aegis of Jerusalem at an early date. Founded by Raymond of Toulouse, between 1102 and 1105, with the favour of Alexius and the alliance of the Genoese, it did not acquire its capital of Tripoli till 1109. Even before the conquest of Tripoli, there had been dissensions between William, the nephew and successor of Raymond, and Bertrand, Raymond's eldest son, which it had needed the interference of Baldwin I. to compose; and it was only by the aid of the king that the town of Tripoli had been taken. At an early date therefore the county of Tripoli had already come under the influence of the kingdom. Meanwhile the principality of Antioch, ruled by Tancred, after the departure of Bohemond (1104–1112), and then by Roger his kinsman (1112–1119), was, during the reign of Baldwin I., busily engaged in disputes both with its Christian neighbours at Edessa and Tripoli, and with the Mahommedan princes of Mardin and Mosul. On the death of Roger in 1119, the principality came under the regency of Baldwin II. of Jerusalem, until 1126, when Bohemund II. came of age. Bohemund had married a daughter of Baldwin; and on his death in 1130 Baldwin II. had once more become the guardian of Antioch. From his reign therefore Antioch may be regarded as a dependency of Jerusalem; and thus when the Latin kingdom of Jerusalem stands complete, with its own boundaries stretching from Beirut in the north to el-Arish and Allen in the south, and with the three Frankish powers of the north admitting its suzerainty.

The Latin power thus established and organized in the East had to face in the north a number of Mahommedan amirs, in the south the caliph of Egypt. The disunion between the Mahommedan amirs of Egypt and the Fatimids of Egypt, and the political disorganization of the former were both favourable to the success of the Franks; but they had nevertheless to maintain their ground vigorously both in the north and the south against almost incessant attacks. The hostility of the decadent caliphate of Cairo was the less dangerous; and though Baldwin I. had at the beginning of his reign to meet annual attacks from Egypt, by the end he had pushed his power to the Red Sea, and in the very year of his death (1118) he had penetrated along the north coast of Egypt as far as Farama (Pelusium). The plan of conquering Egypt had indeed presented itself to the Franks from the first, as it continued to attract them to the end; and it is significant that Godfrey himself, in 1100, promised Jerusalem to the patriarch, "as soon as he should have conquered some other great city, and especially Cairo." But the real menace to the Latin kingdom lay in northern Syria; and here a power was eventually destined to rise, which ousted the kings of Jerusalem in the race for Cairo, and then—with the northern and southern boundaries of Jerusalem in its control—was able to rule the kingdom as it stood between the two arms of a vice. Until 1127, however, the Mahommedans of northern Syria were disunited among themselves. The beginning of the 12th century was the age of the atabegs (regents or statholders). The atabegs formed a number of dynasties, which displaced the descendants of the Seljukian amirs in their various principalities. These dynasties were founded by emancipated maimaliks, who had held high office at court and in camp under powerful amirs, and who, on their death, first became statholders for their descendants, and then usurped the throne of their masters. There was an atabeg dynasty in Damascus founded by Tughtigin (1103–1128); there was another to the N.E., that of the Ortokids, represented by Sokman, who established himself at Kaifa in Diarbekr about 1101, and by his brother Ilghazi, who received Mardin from Sokman about 1108, and added to it Aleppo in 1117. 1 But the greatest of the atabegs were those of Mosul on the Tigris—Maudud, who died in 1113; Aksunkur, his successor; and finally, greatest of all, Zengi himself, who ruled in Mosul from 1124 to 1145.

Before the accession of Zengi, there had been constant fighting, which had led, however, to no definite result, between the various Mahommedan princes and the Franks of northern Syria. The constant pressure of Tancred of Antioch and Baldwin de Burgh of Edessa led to a series of retaliations between 1110 and 1115; Edessa was attacked in 1110, 1111, 1112 and 1114; and in 1113 Maudud of Mosul had even penetrated as far as the vicinity of Acre and Jerusalem. 2 But the disunions of the Mahommedans made their attacks unavailing; in 1115, for instance, we find Antioch actually aided by Ilghazi and Tughtigin against Aksunkur of Mosul. Again, in the reign of Baldwin II., there was steady fighting in the north; Roger of Antioch was defeated by Ilghazi at Balat in 1119, and Baldwin II. himself was captured by Balak, the successor of Ilghazi, in 1123, but on the whole the Franks held the upper hand. Baldwin conquered part of the territory of Aleppo (1121) and the following year he extorted a tribute from Damascus (1126). But when Zengi established himself in Mosul in 1127, the tide gradually began to turn. He created for himself a great and united principality, comprising not only Mosul, but also Aleppo, Harran, Nisibin and other districts; and in 1130, Alice, the widow of Bohemund II., bought his alliance in order to maintain herself in power at Antioch. In the beginning of the reign of Fulk of Jerusalem (1131–1143) the progress of Zengi was steady. He conquered in 1135 several fortresses in the east of the principality of Antioch, and in this year and the next pressed the count of Tripoli hard; while in 1137 he defeated Fulk at Barin, and forced the king to capitulate and surrender the town. If Fulk had been left alone to wage the struggle against Zengi, and if Zengi had enjoyed a clear field against the Franks, the fall of the kingdom of Jerusalem might have come far sooner than it did. 3 But there were two powers which aided Fulk, and impeded the progress of Zengi—the amirate of Damascus and the emperors of Constantinople. The position of Damascus was of great importance from 1130 to 1154. Lying between Mosul and Jerusalem, and important both strategically

---

1 Ilghazi died in 1122. His successor was Balak, who ruled from 1122 to 1124, and succeeding in capturing in 1123 Baldwin II. of Jerusalem. The union of Mardin and Aleppo under the sway of these two amirs, connecting as it did Mesopotamia with Syria, marks an important stage in the revival of Mahommedan power (Stevenson, Crusades in the East, p. 103).  
2 Maudud (the brother of Mahommed) may be regarded as the first to begin the jihad, or counter crusade, and his attack upon the citizens of Damascus in 1113, which carried him so far into the heart of Palestine, may be considered as the first act of the jihad (Stevenson, op. cit., p. 87, note 6).  
3 Aleppo had passed from the rule of Timurtash (son of Ilghazi and successor of Balak) into the possession of Aksunkur, 1125.  
4 Stevenson, however, believes that Zengi was not animated by the idea of recovering Jerusalem. He thinks that his principal aim was simply the formation of a compact Mahommedan state, which was, indeed, in the issue destined to be the instrument of the jihad, but was not so intended by Zengi (op. cit. pp. 123–124).
and from its position on the great route of commerce from the Euphrates to Egypt, Damascus became the arbiter of Syrian politics. But part of the period between 1120 and 1124, the policy of Damascus was guided by the vizier Muin eddin Anar, who ruled on behalf of the descendants of the atabeg Tughtigin. He saw the importance of finding an ally against the ambition of Zengi, who had already attacked Damascus in 1120. The natural ally was Jerusalem. As early as 1123 the alliance of the two powers had been concluded; and in 1140 the alliance was solemnly renewed between Fulk and the vizier. Henceforth this alliance was a dominant factor in politics. One of the great mistakes made by the Franks was the breach of the alliance in 1147—a breach which was widened by the attack directed against Damascus during the Second Crusade; and the conquest of Damascus by Nurreddin in 1154 was ultimately fatal to the Latin kingdom, removing as it did the one possible ally of the Franks, and opening the way to Egypt for the atabegs of Mosul.

The alliance of the emperors of Constantinople was of far more dubious value to the kings of Jerusalem. We have already seen that it was the theory of the Eastern emperors—a theory which logically followed from the homage of the crusaders to Alexius—that the conquests of the crusaders belonged to their empire, and were held by the crusading princes as fiefs. We have seen that the action of Bohemund at Antioch was the negation of this theory, and that Alexius in consequence helped Raymond to establish himself in Tripoli as a thorn in the side of Bohemund, and sent an army and a fleet which wrested from the Normans the towns of Cilicia (1104). The defeat of Bohemund at Durazzo in 1108 had resulted in a treaty, which made Antioch a fief of Alexius; but Tancred (who in 1107 had recovered Cilicia from the Greeks) refused to fulfil the terms of the treaty, and Alexius (who attempted—but in vain—to induce Baldwin I. to join an alliance against Tancred In 1123) was forced to leave Antioch independent. Thus, although Alexius had been able, in the wake of the crusading armies, to recover a large belt of land round the whole coast of Asia Minor,—the interior remaining subject to the sultans of Konia (Iconium) and the princes of Sivas,—he left the territories to the east of the western boundary of Cilicia in the hands of the Latins when he died in 1118. Not for 20 years after his death did the Eastern empire make any attempt to gain Cilicia or wrest hommage from Antioch. But in 1137 John Comnenus appeared, instigated by the opportunity of dissensions in Antioch, and received its long-denied homage, as well as that of Tripoli; while in the following year he entered into hostilities with Zengi, without, however, achieving any considerable result. In 1142 he returned again, anxious to create a principality in Cilicia and Antioch for his younger son Manuel. The people of Antioch refused to submit; a projected visit to Jerusalem, during which John was to unite with Fulk in a great alliance against the Moslem, fell through; and in the spring of 1143 the emperor died in Cilicia, with nothing accomplished. On the whole, the interference of the Comneni, if it checked Zengi for the moment in 1138, may be said to have ultimately weakened and distracted the Franks, and to have helped to cause the loss of Edessa (1144), which marks the turning-point in the history of the kingdom of Jerusalem.

5. Organisation of the Kingdom.—Before we turn to describe the Second Crusade, which the loss of Edessa provoked, and to trace the fall of the kingdom, which the Second Crusade rather hastened than hindered, we may pause at this point to consider the organization of the Frankish colonies in Syria. The first question which arises is that of the relation of the kingdom of Jerusalem to the three counties or principalities of Antioch, Tripoli and Edessa, which acknowledged their dependence upon it. The degree of this dependence was always a matter of dispute. The rights of the king of Jerusalem chiefly appear when there is a vacancy or a minority in one of the principalities, or when there is dissension either inside one of the principalities or between two of the princes. On the death of one of the princes without heirs of full age, the kings of Jerusalem were entitled to act as regents, as Baldwin II. did twice at Antioch, in 1119 and 1130; but the kings regarded this right of regency as a burden rather than a privilege, and it is indeed characteristic of the relation of the king to the three princes, that it imposes upon him duties without any corresponding rights. It is his duty to act as regent; it is his duty to compose the dissensions in the principality of Antioch, and to repress the violence of the prince towards his patriarch (1154); it is his duty to reconcile Antioch with Edessa, when the two fall to fighting. The princes on their side acted independently: if they joined the king with their armies, it was as equals doing a favour; and they sometimes refused to join until they were coerced. They made their own treaties with the Mahommedans, or attacked them in spite of the king's treaties; they dated their documents by the year of their own reign, and they had each their separate laws or assizes. There was, in a word, co-ordination rather than subordination; nor did the kings ever attempt to embark on a policy of centralization.

The relation of the king to his own barons within his immediate kingdom of Jerusalem is not unlike the relation of the king to the three princes. In Normen England the king insisted on his rights; in Frankish Jerusalem the barons insisted on his duties. The circumstances of the foundation of the kingdom explain its characteristics. As the crusaders advanced to Jerusalem, says Raymund of Agiles (c. xxxiii.), it was their rule that the first-comer had the right to each castle or town, provided that he hoisted his standard and planted a garrison there. The feudal nobility was thus the first to establish itself, and the king only came after its institution—the reverse of Norman England, where the king first conquered the country, and then plotted it out among his nobles. The predominance of the nobility in this way became as characteristic of feudalism in the Latin kingdom of Jerusalem as the supremacy of the crown was of contemporary feudalism in England; and that predominance expressed itself in the position and powers of the high court, in which the ultimate sovereignty resided. The kingdom of Jerusalem consisted of a series of baronies, in which the king was to be primus, but in which he was none the less subject to a punctilious law, regulating his position equally with that of every member of the society. In such a society the election of the head by the members may seem natural; and in the case of Godfrey and the first two Baldwins this was the case. But the conception of the equality of the king and his peers in the long run led to hereditary monarchy; for if the king held his kingdom as a fief, like other nobles, the laws of descent which applied to a fief applied to the kingdom, and those laws demanded heredity. Yet the high court, which decided all problems of descent, would naturally intervene if a problem of descent arose, as it frequently did, in the kingdom; and thus the barons had the right of deciding between different claimants, and also of formally "approving" each new successor to the throne. The conception of the kingdom as a fief not only subjected it to the jurisdiction of the high court; it involved the most disastrous result that the kingdom, like other fiefs, might be carried by an heirless to her husband; and the proximate causes of the collapse of the kingdom in 1187 depend on this fact and the dissensions which it occasioned.

Thus conceived as the holder of a great fief, the king had only the rights of suzerain over the four great baronies and the twelve minor fiefs of his kingdom. He had not those rights of sovereign which the Norman kings of England inherited from their Anglo-Saxon predecessors, or the Capetian kings of France from the Carolings; nor was he able therefore to come into direct touch with each of his subjects, which William I., in virtue of his sovereign rights, was able to attain by the Salisbury oath of 1086. Amalric I. indeed, by his assise sur la lignée, attempted to reach the vassals of his vassals; he admitted arrière-vassaux to the haute cour, and encouraged them to carry their cases to it in the first instance. But this is the only attempt at that policy of généralisation which in contemporary England was carried to far greater lengths; and even this attempt was unsuccessful. No alliance was actually formed between the king and the mesne nobility against the immediate baronage. The body of the tenants-in-chief continued to limit the power of the crown:
CRUSADES

533

b Burgess was almost equally sovereign within its sphere. While the body of the noblesse formed the high court, the court of the burgesses was composed of twelve lords (probably named by the leading men of the country) serving during the presidency of the Ricom). A knight also named by the king was a great financial as well as a judicial officer. The province of the court in these acts and contracts between burgesses, and extended to criminal cases in whichburgesses were involved. Like the high court, the court of burgesses had also its assizes—a body of unwritten legal

4 As was noticed above, there were apparently separate assizes for the three principalities, in addition to the assizes of the kingdom. The assizes of Antioch have been discovered and published. The assizes of Tripoli and of the Holy Land are themselves two-fold—the assizes of the high court and the assizes of the court of burgesses. (1) The assizes of the high court are preserved for us in works by legists—John of Ibelin, Philip of Novara and Godfrey of Tort—composed in the 13th century. We possess, in other words, (1) the Bracton's treatise De legibus, but not laws—law-books made after the loss of the kingdom to which the laws belonged. There are two vexed questions with regard to these law-books. (a) The first concerns the origin and character of the laws which the books profess to expound. According to the story of the legists who wrote these books—e.g., John of Ibelin—the laws of the kingdom were laid down by Godfrey, who is thus regarded as the great rovogth of the kingdom. These laws (progressively modified, it is admitted) were written on parchment by clerks of the king's chancellors of the kingdom, and remain in the possession of the king, at least until 1187. In that year they were lost; and the legists tell us that they are attempting to reconstruct par oire die the gist of the lost archetype. The story of the legists is now generally rejected. Concerning the origin of the law-books of the kingdom, gradually evolved, and were gradually defined, especially under kings like Baldwin III, and Amalric I. If there was thus only a customary and unwritten law (and William of Tyre definitely speaks of a jus consuetudinis seu regnum rege regatur), then the “Letters of the Selphchre” are in a myth. Wherever they ever existed, they did not exist as a code of written law, but, perhaps, as a register of fees, like the Sicilian Defetorii. Thus the story of the lets breaks down to the regular myth of the primitive legislator, used to give his words or his decrees, and not record an unwritten custom. The fact is that until the 13th century the Franks lived consuetudinibus antiquis et jure non scripto. They preferred an unwritten law, as Prutz suggests, partly because it suited the barrister (who often belonged to the bourgeoisie), and particularly for the Frankish nobles were “great pleaders in court and out of court”), and partly because the high court was left unobscured so long as there was no written code. In the 13th century it became necessary for the king to hold assizes on a regular basis. The upheavals of the times necessitated the fixing of some rules in writing, and especially because it was necessary to oppose a definite custom of the kingdom to Frederick II, who sought, as king of Jerusalem, to enforce his own ideas of what law ought to be. He substituted his own notions of law in the teeth of the demand for a second law. He used his influence to have a series of difficulties concerns the text of the law-books themselves. The text of Ibelin became a textus receptus—but it also became overlaid by glosses for it was used as authoritative in the kingdom of Cyprus after the loss of Jerusalem, and it became the textus receptus for the Frankish law, which was then used in Cyprus in the later middle ages. At the same time, if our text is thus late, it must be remembered that its content gives us the earliest and purest expression of French feudalism, and describes for us the organization of feudalism in the kingdom of Jerusalem, and the feudal system and its laws, as we possess them, and the monarch was only a suzerain of feudal lands. (2) The assizes of the court of burgesses were the basis of a treatise at an earlier date than the assizes of the high court. The date of the Ibelin treatise is probably (while it was made by some learned burgess) may well have been before the fall of Jerusalem. In this, for instance, they are concerned with the laws of the Assizes for the Franks: he was the first native king, and a king learned in the law; but Beugnot would refer the Assizes to the years immediately preceding Saladin's capture of Jerusalem. These assizes do not, of course, appear in Ibelin, who was only concerned with the feudal law of the high court. They were used, like the assizes of the high court, in Cyprus; and, like the other assizes, they were the subject of investigation in P31, with the object of discovering a good text. The law which has been recovered has been compared with the Græco-Roman law of the Eastern empire which prevailed among the native population of Syria.

In regard to both assizes, it is most important to bear in mind that we possess not laws, but law-books; that custumal records made by lawyers for their fellows of what they conceived to be the law, and supported by legal arguments and citations of cases. But, as Prutz remarks, Philip of Novara lehr nicht die Wissenschaft des Rechts, sondern die Unrechts; he does not explain the law so much as the ways of getting round it.

1 There are certain connexions and analogies between the kingdom of Sicily and that of Jerusalem during the twelfth century. In either case there is an importation of Western feudalism into a country originally possessed of Byzantine institutions, but affected by an Arab civilization. The subject preserves invested in the person of the king, and the title of the king, 2 The holders of fiefs (sodiers) both held fiefs of land and received pay; the paid force of soudiers only received pay. An instance of the latter is furnished by John of Margat, a vassal of the seignior of Jerusalem. He was called upon to provide with a quantity of wheat, barley, lentils and oil; and in return he must march with horses (Rev. Les Colonies françoises en Syrie, p. 24).

3 For the history of the orders see the articles on the TEMPLES, the KNIGHTS OF JERUSALEM, KNIGHTS OF KNIGHTS, and the TEUTONIC ORDER. The Templars were founded about the year 1118 by a Burgundian knight, Hugh de Pagnan; the Hospitalers sprang from a foundation in Jerusalem erected by merchants of Amalfi before the First Crusade, and were reorganized under Gerard le Puy, master until 1120. The Teutonic knights date from the Third Crusade.
custom. The independent position of the burgesses, who thus assumed a position of equality by the side of the feudal class, is one of the peculiarities of the kingdom of Jerusalem. It may be explained by reference to the peculiar conditions of the kingdom. Burgesses and nobles—however different in status, were both of the same Frankish stock, and both occupied the same superior position with regard to the native Syrians. The commercial motive, again, had been one of the great motives of the crusade; and the class which was impelled by that motive would be both large and, in view of the quality of the Eastern goods in which it dealt, exceptionally prosperous. Finally, when one remembers how, during the First Crusade, the pedites had marched side by side with the principes, and how, from the beginning of 1099, they had practically risen in revolt against the selfish ambitions of princes like Count Raymond, it becomes easy to understand the independent position which the burgesses assumed in the organization of the kingdom. Burgesses could buy and possess property in towns, which knights were forbidden to acquire; and though they could not intermarry with the feudal classes, it was easy and regular for a burgess to thrive to knighthood. Like the nobles, again, the burgesses had the right of confirming royal grants and of taking part in legislation; and they may be said to have formed—socially, politically and judicially—an independent and powerful estate. Yet (with the exception of Antioch, Tripoli and Acre in the course of the 13th century) the Frankish towns never developed a communal government: the domain of their development was private law and commercial life.

Locally, the consideration of the system of justice administered in the kingdom involves some account of three things—the organization of the fiefs, the position of the Italian traders in their quarters, and the privileges of the Church. Each fief was organized like the kingdom. In each there was a court for the nobles, a court and a court (or courts) for the bourgeoisie. There were some thirty-seven cours de bourgeoisie (several of the fiefs having more than one), each of which was under the presidency of a vicomte, while all were independent of the court of burgesses at Jerusalem. Of the feudal courts there were some twenty-two. Each of these followed the procedure and the law of the high court; but each was independent of the high court, and formed a sovereign court without any appeal. On the other hand, the revolution wrought by Amalric I. in the status of the arrièrevassaux, which made them members of the high court, allowed them to carry their cases to Jerusalem in the first instance, if they desired. Apart from this, the characteristic of seigniorial justice is its independence and its freedom from the central court; though, when we reflect that the central court is a court of seigneurs, this characteristic is seen to be the logical result of the whole system. Midway between the seigniorial cours de bourgeoisie and the privileged jurisdictions of the Italian quarter, there were two kinds of courts of a commercial character—the cours de la fonde in towns where trade was busy, and the cours de la chaine in the sea-ports. The former courts, under their bailiffs, gradually absorbed the separate courts which the Syrians had at first been permitted to enjoy under their own rois; and the bailiff with his 6 assessors (4 Syrians and 2 Franks) thus came to judge both commercial cases and cases in which Syrians were involved. The cours de la chaine, whose institution is assigned to Amalric I. (1162-1174), had a civil jurisdiction in admiralty cases, and, like the cours de la fonde, they were composed of a bailiff and his assessors. Distinct from all these courts, if similar in its sphere, is the court which the Italian quarter generally enjoyed in each town under its own consuls—a court privileged to try all but the graver cases, like murder, theft and forgery. The court was part of the general immunity which made these quarters imperia in imperio: their exemptions from tolls and from financial contributions is parallel to their judicial privileges. Regulated by their mother-town, both in their trade and their government, these Italian quarters ousted the collapse of the kingdom, and continued to exist under Mahommedan rulers. The Church had its separate courts, as in the West; but their province was perhaps greater than elsewhere. The church courts could not indeed decide cases of perjury; but, on the other hand, they tried all matters in which clerical property was concerned, and all cases of dispute between bishops and widows. In other spheres the immunities and exemptions of the Church offered a far more serious problem, and especially in the sphere of finance. Perhaps the supreme defect of the kingdom of Jerusalem was its want of any financial basis. It is true that the king had a revenue, collected by the vicomte and paid into the secretum or treasury—a revenue composed of tolls on the caravans and customs from the ports, of the profits of monopolies and the proceeds of justice, of poll-taxes on Jews and Mahommedans, and of the tributes paid by Mahommedan powers. But his expenditure was large: he had to pay his feudatories; and he had to provide fiefs in money and kind to those who had not fiefs of land. The contributions sent to the Holy Land by the monarchs of western Europe, as communications in lieu of personal participation in crusades, might help; the fatal policy of razzias against the neighbouring Mahommedan powers might procure temporary resources; but what was really necessary was a wide measure of native taxation, such as was once, and once only, attempted in 1183. To any such measure the privileges of the Italian quarters, and still more those of the Church, were inimical. In spite of provisions somewhat parallel to those of the English statute of mortmain, the clergy continued to acquire fresh lands at the same time that they refused to contribute to the defence of the kingdom, and rigorously exacted their full quota of tithe from every source which they could tap, and even from booty captured in war. The richest proprietor in the Holy Land, but practically immune from any charges on its property, the Church helped, unconsciously, to ruin the kingdom which it should have supported above all others. It refused to throw its weight into the scale, and to strengthen the hands of the king against an over-mighty nobility. On the other hand, it must be admitted that the Church did not, after the first struggle between Dagobert and Baldwin I., actively oppose by any hierarchical pretensions the authority of the crown. The assizes may speak of patriarch and king as joint seigneurs in Jerusalem; but as a matter of fact the king could secure the nomination of his own patriarch, and after Dagobert the patriarchs are, with the temporary exception of Stephen in 1128, the confidants and supporters of the kings. It was the two great orders of the Templars and the Hospitallers which were, in reality, most dangerous to the kingdom. Honeycombed as it was by immunities—of seigneurs, of Italian quarters, of the clergy—the kingdom was most seriously impaired by these overweening immunities, who, half-lay and half-clerical, took advantage of their ambiguous position to escape from the duties of either character. They built up great estates, especially in the principality of Tripoli; they quarrelled with one another, until their dissensions prevented any vigorous action; they struggled against the claims of the clergy to tithes and to rights of jurisdiction; they negotiated with the Mahommedans as separate powers; they conducted themselves towards the kings as independent sovereigns. Yet their aid was as necessary as their influence was noxious. Continually recruited from the West, they retained the vigour which the native Franks of Palestine gradually lost; and their corporate strength gave a weight to their arms which made them indispensable.

In describing the organization of the kingdom, we have also been describing the causes of its fall. It fell because it had not the financial or political strength to survive. "Les vices du gouvernement avaient été plus puissants que les vertus des gouvernants." But the vices were not only vices of the government: they were also vices, partly inevitable, partly moral, in the governing race itself. The climate was no doubt responsible for much. The Franks of northern Europe attempted to live a life that suited a northern climate under a southern sun. They rode incessantly to battle over burning sands, in full armour.  

---

1 For instance, the abbey of Mount Sion had large possessions, not only in the Holy Land (at Ascalon, Jaffa, Acre, Tyre, Caesarea and Tarsus), but also in Sicily, Calabria, Lombardy, Spain and France (at Orleans, Bourges and Poitiers).
CRUSADES

535

—chain mail, long shield and heavy casque—as if they were on their native French soil. The ruling population was already spread too thin for the work which it had to do; and exhausted by its efforts, it gradually became extinct. A constant immigration from the West, bringing new blood and recruiting a new aristocracy, could alone have maintained its vigour; and such immigration never came. Little driblets of men might indeed be added to the numbers of the Franks; but the great bodies of crusaders either perished in Asia Minor, as in 1101 and 1147, or found themselves thwarted and distrusted by the native Franks. It was indeed one of the misfortunes of the kingdom that its inhabitants could never welcome the reinforcements which came to their aid. The barons suspected the crusaders of ulterior motives, and of designing to get new principalities for themselves. In any case the native Frank, accustomed to commercial intercourse and diplomatic negotiations with the Mahomedans, could hardly share the unreasonable passion to make a dash for the "infidel." As with the barons, so with the bourgeois: they profited too much by their intercourse with the Mahomedans to abandon readily the way of peaceful commerce, and they were far more ready to hinder than to help any martial enterprise. Left to itself, the native population lost physical and moral vigour. The barons alternated between the extravagances of Western chivalry and the attractions of Eastern luxury: they returned from the field to divans with frescoed walls and floors of mosaics, Persian rugs and embroidered silk hangings. Their houses, at any rate those in the towns, had thus the characteristics of Moorish villas; and in them they lived in a most luxurious style. The women wore the gauzes and the copper and silver work of Eastern smiths and the confectioneries of Damascus. They dressed in flowing robes of silk, and their women wore oriental gauzes covered with sequins. Into these divans where figures of this kind moved to the music of Saracen instruments, there entered an inevitable voluptuousness and corruption of manners. The hardships of war and the excesses of peace shortened the lives of the men; the kingdom of Jerusalem had eleven kings within a century. While the men died, the women, living in comparative indolence, lived longer lives. They became regents to their young children; and the experience of all medieval minorities reiterates the lesson—woe to the land where the king is a child and the regent a woman. Still worse was the frequent remarriage of widoweds princesses and heiresses. By the assizes of the high court, the widow, on the death of her husband, took half of the estate for herself, and half in guardianship for her children. Liberae ire cum terra, widows carried their estates or titles to three or four husbands; and as in 13th-century England, the influence of the heiress was fatal to the peace of the country. At Antioch, for instance, after the death of Bohemond II. in 1130, his widow Alice headed a party in favour of the marriage of the heiress Constance to Manuel of Constantinople, and did not scruple to enter into negotiations with Zengi of Mosul. Her policy failed; and Constance subsequently married Raymond of Antioch and Raynald of Chatillon. The result was the renewed enmity of the Greek empire, while the French adventurers who won the prize ruined the prospects of the Franks by their conduct. In the kingdom matters were almost worse. There was hardly any regular succession to the throne; and Jerusalem, as Stubbs writes, "suffered from the weakness of hereditary right and the jealousies of the elective system." At one and the same time. With the frequent remarriages of the heiresses of the kingdom, relationships grew confused and family quarrels frequent; and when Sibylla carried the crown to Guy de Lusignan, a new-comer disliked by all the relatives of the crown, she sealed the fate of the kingdom.

It may be doubted—that it seems a harsh verdict to pass on a kingdom founded by religious zeal on holy soil—whether the kingdom possessed that moral basis which alone can give a right of survival to any institution or organization. The crusading states had been founded by adventurers who thirsted for gain, and the primitive virtues did not lose its edge with the progress of time. We cannot be certain, indeed, how far the Frankish lords oppressed their Syrian tenants: the stories of such oppression have been discredited; while if we may trust the evidence of a Mahomedan traveller, Ibn Jubair, the lot of the Mahomedan who lived on Frankish manors was better than it had been under their native lords. But the habits of the Franks were none the less habits of lawless greed: they swooped down from their castles, as Raynald of Chatillon did from Krak of the Desert, to capture Saracens and hold them to ransom or to plunder caravans. The lust of unlawful gain had infected the Frankish blood, as it seems to have infected England during the Hundred Years' War; and in either case nemesis infallibly came. The Moslems might have endured a state of "infidels"; they could not endure a state of brigands.

6. The History of the Kingdom and the Crusades from the Loss of Edessa in 1144 to the Fall of Jerusalem in 1187.—The years 1143-1144 are in many ways the turning point in the history of the Latin East. In 1143 began the reign of the first native king; and about this date may be placed the final organization of the kingdom, witnessed by the completion of its body of customary law. At the same time, however, the decline of the kingdom also begins; the fall of Edessa is the beginning of the end. In 1143 John Connenus and Fulk had just died, and Zengi, seeing his way clear, threw himself on the great Christian outposts, against which the weakened Edessene attack had so often vainly surged, and finally entered on Christmas Day 1144. Two years later Zengi died; but he left an able successor in his son, Nurreddin, and an attempt to recover Edessa was successfully repelled in November 1146. Not only so, but in the spring of 1147 the Franks were unwisely enough to allow the hope of gaining two small towns to induce them to break the vital alliance with Damascus. Thus, in itself, the position of affairs in the Holy Land in 1147 was certainly ominous; and the kingdom might well seem dependent for its safety on such aid as it might receive from the West.

Early in 1145 news had come from Antioch to Eugenius III. of the fall of Edessa, and at the end of the year he had sent an encyclical to France—the natural soil, as we have seen, of crusading zeal. The response was instantaneous: the king of France himself, who bore on his conscience the burden of an unpunished massacre by his troops at Vitry in 1142, took the crusading vow on the Christmas day of 1145. But the greatest success was attained when St Bernard—no great believer in pilgrimages, and naturally disposed to doubt the policy of a second Crusade—was induced by the pope to become the preacher of the new movement. To the crusading king of

2 The manorial system in the Latin kingdom of Jerusalem was a continuation of the village system as it had existed under the Arabs. In each village (castal) the rustici were grouped in families (foci); and tenants paid from 1/2 to 1/3 of the crop, besides a poll-tax and labour-dues. The villages were mostly inhabited by Syrians: it was rarely that Franks settled down as tillers of the soil. Prutz regards the manorial system as oppressive. Absentee landlords, he says, rack-rented the soil (p. 167), while the "inhuman severity of their treatment led to a progressive decay of agriculture, destroyed the economic basis of the Latin kingdom, and led the natives to welcome the invasion of Saladin (pp. 327-331).

The French writers Rey and Duod are more kind to the Franks; and the Syrians testify that they were strongly impressed by the treatment of their subjects by the Franks, bears out their view, while the tone of the assizes is admittedly favourable to the Syrians. One must not forget that there native manufacture of carpets, pottery, ironwork, gold-work and soap; or that the Syrians of the towns had a definite legal position.

3 After 1143 one may therefore speak of the period of the Epigonii—the native Franks, ready to view the Moslems as joint occupants of Syria and to imitate the dress and habits of their neighbours.

4 Doubt has been cast on the view that a troubled conscience drove Louis to take the cross; and his action has been ascribed to simple religious zeal (cf. Lavisse, Histoire de France, iii. 12).
France St Bernard added the king of Germany, when, in Christmas week of 1146, he induced Conrad III. to take the vow by his sermon in the cathedral of Spire. Thus was born the Second Crusade: under auspices still more favourable than those which attended the beginning of the First, that kings now took the place of knights, while the new crusaders would not longer be penetrating into the wilds, but would find a friendly basis of operations ready to their hands in Frankish Syria. But the more favourable the auspices, the greater proved the failure. Already at the final meeting at Étampes, in 1147, difficulties arose. Manuel Comnenus demanded that all conquests made by the crusaders should be his fiefs; and the question was debated whether the crusaders should follow the land route through Hungary, along the old road of Charlemagne, or should go by sea to the Holy Land. In this question the envoys of Manuel and of Roger of Sicily, who were engaged in hostilities with one another, took opposite sides. Conrad, related by marriage to Manuel, decided in favour of the land route, which Manuel desired because it brought the Crusade more under his direction, and because, if the route by sea were followed, Roger of Sicily might be able to divert the crusading ships against Constantinople. As it was, a struggle raged between Roger and Manuel during the whole progress of the Crusade, which greatly contributed to its failure. In the end, the latter was forced to give way, and the crusaders found no any assistance from the Eastern empire. Nor was there any real unity among the crusaders themselves. The crusaders of northern Germany never went to the Holy Land at all; they were allowed the crusaders' privileges for attacking the Wends to the east of the Elbe—a fact which at once attests the cleavage between northern and southern Germany (intensified of late years by the war of investitures), and anticipates the age of the Teutonic knights and their long Crusade on the Baltic. The crusaders of the Low Countries and of England took the sea route, and attacked and captured Lisbon on their way, thus helping to found the kingdom of Portugal, and achieving the one real success which was gained by the Second Crusade. Among the great army of crusaders who actually marched to Jerusalem there was little real unity. Conrad and Louis VII. started separately, and at different times, in order to avoid dissensions between their armies; and when they reached Asia Minor (after encountering some difficulties in Greek territory) they still acted separately. Eager to win the first spoils, the German crusaders, who were in advance of the French, attempted a raid into Armenia, under Conrad's command; but after a stern fight at the Hama, on the plains of which they were forced to retreat (October 1148), and for the most part perished by the way. Louis VII., who now appeared, was induced by this failure to take the long and circuitous route by the west coast of Asia Minor; but even so he had lost the majority of his troops when he reached the Holy Land in 1148. Here he joined Conrad (who had come by sea from Constantinople) and Baldwin III., and after some deliberation the three sovereigns resolved to attack Damascus. The attack was impolitic: Damascus was the one ally which could help the Franks to stem the advance of Nureddin. It proved as futile as it was impolitic; for the vizier of Damascus, Muin-ed-din-Anar, was able to sow dissension between the native Franks and the crusaders; and by bribes and promises of tribute he succeeded in inducing the former to make the siege an absolute failure, at the end of only four days (July 28th, 1148). The Second Crusade now collapsed. Conrad returned to Constantinople in the autumn of 1148, and Louis VII. returned by sea to France in the spring of 1149. The only effects of this great movement were effects prejudicial to the ends towards which it was directed. The position of the Franks in the Holy Land was not improved by the attack on Damascus; while the ignominious failure of a Crusade led by two kings brought the whole crusading movement into discredit in western Europe, and it was utterly in vain that Suger and St Bernard attempted to gather a fresh Crusade in 1150.

The result of the failure of the Second Crusade was the renewal of Nureddin's attacks. The rest of the county of Edessa, including Tell-bashir on the west, was now conquered (1150); while Raymund of Antioch was defeated and killed (1149), and several times the claims of his principality were captured. Baldwin III. attempted to make peace against these troubles partly by renewing the old alliance with Damascus, partly by drawing closer to Manuel of Constantinople. For the next twenty years, during the reigns of Baldwin and his brother Amalric I., there is indeed a close connexion between the kingdom of Jerusalem and the East Roman empire. Baldwin and Amalric both married into the Comnenian house, while Manuel married Mary of Antioch, the daughter of Raymund. In the north Manuel enjoyed the homage of Antioch, which his father had gained in 1137, and the nominal possession of Tell-bashir, which had been ceded to him by Baldwin III.: in the south he joined with Amalric I. in the attempt to acquire Egypt (1168-1171). In this way he acquired a certain ascendency over the Latin kings: Baldwin III. rode behind him at Antioch in 1159 without any of the insignia of royalty, and in an inscription at Bethlehem of 1172 Amalric I. had the name of the emperor written above his own. The patronage of Constantinople, to which Jerusalem was thus practically surrendered, contributed to some slight extent in maintaining the kingdom against Nureddin. But there were dangers in the Near East, both between Baldwin and his mother, Mellisinda, who sought to extend her regency unduly, and between contending parties in Antioch, where the hand of Constance, Raymund's widow, was a desirable prize; while from without the horns of the crescent were slowly closing in on the kingdom. Nureddin pursued in his policy the tactics which the Mahomedans used against the Franks in battle: he sought to envelop their territories on every side. In 1154 fell Damascus, and the crescent closed perceptibly in the north: the most valuable ally of the kingdom was lost, and the way seemed clear from Aleppo (the peculiar seat of Nureddin's power) into Egypt. On the other hand, in 1153 Baldwin III. had taken Ascalon, which for fifty years had mocked the efforts of successive kings, and by this stroke he might appear to have closed for Nureddin the route to Egypt, and to have opened a path for its conquest by the Franks. For the future, events hinged on the situation of affairs in Egypt, and in Egypt the fate of the kingdom of Jerusalem was finally decided (see Egypt: History, "Mahomedan Period"). There was a race for the possession of the country between Nureddin's lieutenant Shirghûr or Shirkhû and Al-Malik, the brother and successor of Baldwin III.; and in the race Shirkhû proved the winner.

Since the days of Godfrey and Baldwin I., Egypt had been a

1 We speak of First, Second and Third Crusades, but, more exactly, the Crusades were one continuous process. The services which passed in which new bands did not come to the Holy Land. We have already noticed the great if disastrous Crusade of 1100–1101, and the Venetian Crusade of 1122–1124; and we may also refer to the Crusade of Henry the Lion in 1122, and to that of Edward I. in 1270, often called Crusades, which are no longer observed in usual numbering. Crusades appear to have been dignified by numbers when they followed some crushing disaster—the loss of Edessa in 1144, or the fall of Jerusalem in 1187—and were led by kings or emperors; on the other hand, the Fourth and Fifth Crusades, they achieved some conspicuous success or failure. But it is important to bear in mind the continuity of the Crusades—the constant flow of new forces eastward and back again westward; for this alone accounts for why crusades are reckoned in civilization, familiarising, as they did, the West with the East.

2 This body of crusaders ultimately reached the Holy Land, where it joined Conrad (who had lost his own original forces), and helped to make the fruitless siege of Damascus. The services which were rendered to Portugal were repeated by later crusaders. Crusaders from the Low Countries, England and the Scandinavian north took the coast route round western Europe; and it was natural that, landing for provisions and water, they should be asked, and should consent, to lend their aid to the natives against the Moors. Such aid is recorded to have been given on the Third and the Fifth Crusades.

3 The prize was won by Raynald of Chartillon (g.v.).
CRUSADES

537

goal of Latin ambition, and the capture of Ascalon must obviously have given form and strength to the projects for its conquest. Plans of attack were sketched: routes were traced: distances were measured; and finally in 1163 there came the impulse from within which turned these plans into action. The Shiite caliphs of Egypt were by this time the playthings of contending viziers, as the Sunnite caliphs of Bagdad had long been the puppets of Turkish sultans or amirs; and in 1164 Amalric I. and Nureddin were fighting in Egypt in support of two rival viziers, Dirgham and Shawar. For Nureddin the fight meant the acquisition of an heretical country for the true faith of the Sunnite, and the final enveloping of the Latin kingdom: 1 for Amalric it meant the escape from Nureddin’s net, and a more direct and lucrative contact with Eastern trade. Into the vicissitudes of the fight it is not necessary here to enter; but in the issue Nureddin won, in spite of the support which Manuel gave to Amalric. Nureddin’s Kurdish lieutenant, Shrigth, succeeded in establishing in power the vizier whom he favoured, and finally in becoming vizier himself (January 1160); and when he died, his nephew Saladin (Sala-Ed-din) succeeded to his position (March 1169), and made himself, on the death of the caliph in 1171, sole ruler in Egypt. Thus the Shiite caliphate became extinct: in the mosques of Cairo the name of the caliph of Bagdad was now used; and the long-disputed Mahomedans at last faced the Christians as a solid body. But nevertheless the kings of Jerusalem continued for a time to enjoy in the East a practical autonomy. 2

of Amalric I., carried to her husband—a French adventurer—a presumptive title to the crown, which would never be admitted without dispute. In 1186 Guy had eventually become king, after the death of Baldwin V. (Sibylla’s son by her first marriage); but his coronation was in violation of the promise given to Raymund of Tripoli (that in the event of the death of Baldwin V. without issue the succession should be determined by the pope, the emperor and the kings of France and England), and Guy, with a weak title, was unable to exercise any real control over the kingdom. At this point another French adventurer, who had already made himself somewhat of a name in Antioch, gave the final blow to the kingdom. Raymond of Chatillon, the second husband of Constance of Antioch, after languishing in captivity from 1159 to 1176, had been granted the seignory of Krak, to the east and south of the Dead Sea. From this point of vantage he began depredations on the Red Sea (1182), building a fleet, and seeking to attack Medina and Mecca—a policy which may be interpreted either as mere buccaneering, or as a calculated attempt to deal a blow to Mahomedanism in its very centre. Driven from the Red Sea by Saladin, he turned from buccaneering to brigandage, and infested the great trade-route from Damascus to Egypt, which passed close by his seignory. In 1186 he attacked a caravan in which the sister of Saladin was travelling, thus violating a four years’ truce, which, after some two years’ skirmishing, Saladin and Raymund of Tripoli had made in the hope of attaining a more lasting peace. The king, however, could not put to the test a truce as well as a war, owing to the general prevalence of famine. 3

The coronation of one French adventurer and the conduct of another, whom the first was unable to control, meant the ruin of the kingdom; and Saladin at last delivered in full force his long-deferred attack. The Crusade was now at last answered by the counter-Crusade—the "jihad;" for though for many years past Saladin had, in his attempt to acquire all the inheritance of Nureddin, left Palestine unmenaced and intact, his ultimate aim was always the holy war and the recovery of Jerusalem. The acquisition of Aleppo could only make that supreme object more readily attainable; and so Saladin had spent his time in acquiring Aleppo, but only in order that he might ultimately "attain the goal of his desires, and set the mosque of Asha free, to which Allah once led in the night his servant Mahomet." Thus it was on a kingdom of Crusaders who had lost the crusading spirit that a new Crusade swept down; and Saladin’s army in 1187 had the spirit and the fire of the Latin Crusaders of 1099. The tables were turned; and fighting on their own soil for the recovery of what was to them too a holy place, the Mahomedans easily carried the day. At Tiberias a little squadron of the brethren of the Order of Saint John was destroyed, and at Acre, under the leadership of Saint Louis, the Second Order was carried off (May 21). At Jaffa, and in the environs of the city, the Copts were put to the sword; and when the Copts asked for the protection of the truce, the king, after the murder of a Cope, refused to listen to the complaint. 4

The hour of peril for the Latin kingdom had now at last struck. It had done little to prepare itself for that hour. Repeated appeals had been made to the West from the beginning of the Egyptian affair (1163) onwards; while in 1184–1185 a great mission, on which the patriarch of Jerusalem and the masters of the Templars and the Hospitallers were all present, came to France and England, and offered the crown of Jerusalem to Philip Augustus and Henry II. in turn, in order to secure their presence in the Holy Land. 2 The only result of these appeals was the rise of a regular system of taxation in France and England, ad sustentationem Jerusolimitanarum terrarum, which starts about 1185 (though there had already been isolated taxes in 1147 and 1166), and which has been described as the beginning of modern taxation. In the East itself, with the exception of the tax of 1183; 3 nothing was done that was good, and two things were done which were evil. Sibylla married her second husband, Guy de Lusignan, in 1180—a marriage destined to be the cause of many dissensions; for Sibylla, the eldest daughter

1 Nureddin, unlike his father, was definitely animated by a religious motive: he fought first and foremost against the Latins (and not, like his father, against Moslem states), and he did so as a matter of religious duty.

2 Henry II., as an Angevin, was the natural heir of the kingdom of Jerusalem on the extinction of the line descended from Fulk of Anjou. This explains the part played by Richard I. in deciding the question of the succession during the Third Crusade.

3 The taxation levied in the West was also attempted in the East, and in 1183 a universal tax was levied in the kingdom of Jerusalem, at the rate of 1% on movables and 2% on rents and revenues. Cf. Dr A. Cartellieri, Philip II. August. ii. pp. 3-18 and p. 85.

4 Stevenson argues (op. cit. p. 240) that this truce was already practically dissolved before Raynal died, and that Raynal’s action may reasonably be viewed as the practical outcome of the feeling of a party.”
CRUSADES

Greeks; lastly, there are the Crusades waged by the papacy against revolted Christians—John of England and Frederick II. One concern lies with the first kind of Crusade, and with the other three only so far as they bear on the first, and as they illustrate the immense widening by which the term “Crusade” now underwent—a widening accompanied by its inevitable corollary of shallowness of motive and degradation of impulse.

The Third Crusade, 1189-1192.—Conrad of Montferrat was, as much as any one man, responsible for the Third Crusade. Compelled to leave the court of Constantinople, which he had been serving, he had sailed for the Holy Land and reached Tyre about three weeks after the battle of Hattin. He had saved Tyre; and from it he sent his appeals to the West. Not the least effective of these appeals was a great poster which he had circulated in Europe, and which represented the Holy Sepulchre defiled by the horses of the Mahomedans. Meanwhile the papacy, as soon as the news reached Rome, despatched encyclical letters throughout Europe; and soon a new Crusade was in full swing. But the Third Crusade, unlike the First, does not spring from the papacy, which was passing through one of its epochs of depression; it springs from the lay power, which, represented by the three strong monarchies of Germany, England and France, was at this time dominant in Europe. In Germany it was the solemn national diet of Mainz (Easter 1188) which “saw the expedition” to the Holy Land; in France and England the agreement of the two kings decided upon a joint Crusade. The very means which Philip Augustus and Henry II. took, in order to further the Crusade, show its lay aspect. A scheme of taxation—the Saladin tithe—was imposed on all who did not take the cross; and this taxation, while on the one hand it drove many to take the cross in order to escape its incidence, on the other hand provided a necessary financial basis for military operations.1 The lay basis of the Third Crusade made it, in one sense, the greatest of all Crusades, in which all the three great monarchs of Western Europe participated; but it also made it a failure, for the kings of France and England, changing causum non veniam, carried their political rivalries into the movement, in which it had been agreed that they should be sunk. Spiritually, therefore, the Third Crusade is inferior to the First, however imposing it may be in its material aspects. Yet it must be admitted that the idea of a spiritual regeneration accompanied the crusading movement of 1188. Europe had sinned in the face of God; otherwise Jerusalem would never have fallen; and the idea of a spiritual reform from within, as the necessary corollary and accompaniment of the expedition of Christianity without, breathes in some of the papal letters, just as, during the conciliar movement, the causa reformations was blended with the causa unionis.

We may conceive of the Third Crusade under the figure of a number of converging lines, all seeking to reach a common centre. That centre is Acre. The siege of Acre, as arduous and heroic in many of its episodes as the siege of Troy, had been begun in the summer of 1189 by Guy de Lusignan, who, captured by Saladin at the battle of Hattin, and released on parole, had at last found a pretext and returned to the attack. The army which was besieging Acre was soon joined by various contingents; for Acre, after all, was the vital point, and its capture would open the way to Jerusalem. Two of these contingents alone concern us here—the German and the Anglo-French. Frederick I. of Germany, using a diplomacy which corresponds to the lay character of the Third Crusade, had sought to prepare his way by embassies to the king of Hungary, the Eastern emperor and the sultan of Iconium. Starting from Regensburg in May 1189, the German army marched quietly through Hungary; but difficulties arose, as they had arisen in 1147, as soon as the frontiers of the Eastern empire were reached. The emperor Isaac Angelus had not only the old grudge of all Eastern emperors against the “upstart” emperor of the West; he had also allied himself with Saladin, in order to acquire for his empire the patronage of the Holy Places and religious supremacy in the Levant. The difficulties between Frederick and Isaac Angelus became acute: in November 1189 Frederick wrote to his son Henry, asking him to induce the pope to preach a Crusade against the schismatic Greeks. But terms were at last arranged, and by the end of March 1190 the Germans had all crossed to the shores of Asia Minor. Taking a route midway between the eastern route of the crusaders of 1097 and the western route of Louis VII. in 1148, Frederick marched by Philadelphia and Iconium, not without dust and heat, until he reached the river Salaf, in Armenian territory. Here, with the burden of the day now past, the fine old crusader—he had joined before in the Second Crusade, forty years ago—perished by accident in the river; and of all his fine army only a thousand men won their way through, under his son, Frederick of Swabia, to join the ranks before Acre (October 1190). The Anglo-French detachment achieved a far greater immediate success. War had indeed disturbed the original agreement of Gisors between Philip Augustus and Henry II., but a new agreement was made between Henry’s successor, Richard I., and the French king at Nonancourt (December 1189), by which the two monarchs were to meet at Vezelay next year, and then to follow the sea route to the Holy Land together. They met, and by different routes they both reached Sicily, where they wintered together (1190-1191).

The enforced inactivity of a whole winter was the mother of disputes and bad blood; and when Philip sailed for the Holy Land, at the end of March 1191, the failure of the Crusade was already decided. Richard soon followed; but while Philip sailed straight for Acre, Richard occupied himself by the way in conquering Cyprus—partly out of knight-errantry, and in order to avenge an insult offered to his betrothed wife Berengaria by the despot of the island, partly perhaps out of policy, and in order to provide a basis of supplies and of operations for the armies attempting to recover Palestine. In any case, he is the founder of the Latin kingdom of Cyprus (for he afterwards sold his new acquisition to Guy de Lusignan, who established a dynasty in the island); and thereby he made possible the survival of the institutions and assizes of Jerusalem, which were continued in Cyprus until it was conquered by the Ottoman Turks. From Cyprus Richard sailed to Acre, arriving on the 8th of June, and in little more than a month he was able, in virtue of the large reinforcements he brought, and in spite of dissensions in the Christian camp which he helped to foment, to bring the two years’ siege to a successful issue (July 12th, 1191): It was indeed time; the privations of the besiegers during the previous winter had been terrible; and the position of affairs had only been made worse by the dissensions between Guy de Lusignan and Conrad of Montferrat, who had begun to claim the crown in return for his services, and had, on the death of Sibylla, the wife of Guy, reinforced his claim by a marriage with her younger sister, Isabella. In these dissensions it was inevitable that Philip Augustus and Richard I., already dissatisfied, should take contrary sides; and while Richard naturally sided with Guy de Lusignan, who was the heir of his wife, Philip sided—though he was only of Poitou, Philip as naturally sided with Conrad. At the end of July it was decided that Guy should remain king for his life, and Conrad should be his successor; but as three days afterwards Philip Augustus began his return to France (pleading ill-health, but in reality eager to gain possession of Flanders), the settlement availed little for the success of the Crusade. Richard stayed in the Holy Land for another year, during which he won a battle at Arsuf and retook Jaffa. But far more important than any hostilities are the negotiations which, for the whole year, Richard conducted with Saladin. They show the lay aspect of the Third Crusade; they anticipate the Crusade of Frederick II.—for Richard was attempting to secure the same concessions which Frederick secured by the same means which he used. They show again the closer approximation and better understanding with the Mahomedans, which marks this Crusade. Nothing is more striking in these
respects than Richard's proposal that Saladin's brother should marry his own sister Johanna and receive Jerusalem and the contiguous towns on the coast. In the event, a peace was made for three years (September and, 1192), by which Jerusalem and Ramla were to be equally divided, Ascalon was to be destroyed, and small bodies of crusaders were to be allowed to visit the Holy Sepulchre. Meanwhile Conrad of Montferrat, at the very instant when his superior ability had finally forced Richard to recognize him as king, had been assassinated (April 1192): Guy de Lusignan had bought Cyprus from Richard, and had sailed away to establish himself there; and Henry of Champagne, Richard's nephew, had been called to the throne of Jerusalem, and had given himself a title by marrying Conrad's widow, Isabella. In this condition Richard left the Holy Land, when he began his eventful return, in October 1192. The Crusade had failed—failed because a leaderless army, torn by political dissensions and fighting on a foreign soil, could not succeed against forces united by religious zeal under the banner of a leader like Saladin. Yet it had at any rate saved for the Christians the principalities of Antioch, the county of Tripoli, and some of the coast towns of the kingdom; and if it had failed to accomplish its object, it had left behind, none the less, many important results. The difficulties which had arisen between the leaders of the Third Crusade were germs of the Fourth Crusade; the negotiations between Richard and Saladin contain the germs of the Sixth. National rivalries had been accentuated and national differences brought into prominence by the meeting of the nations in a common enterprise; while, on the other hand, Mahommedans and Christians had fraternized as they had never done before during the progress of a Crusade. But what the Third Crusade showed most clearly was that the crusading movement was being lost to the papacy, and becoming part of the demesne of the secular state—organized by the state on its own basis of taxation, and conducted by the state according to its own method of negotiation. This after all is the great change; and even the genius of an Innocent III. could not make undone what had once been done."

On the contrary, the thing once done would go further; and the state would take up the name of Crusade in order to cover, and under such cover to achieve, its own objects and ambitions, as in the future it was destined to do.

The Fourth Crusade, 1202-1204. The history of the Fourth Crusade is a history of the predominance of the lay motive, of the attempt of the papacy to escape from that predominance, and to establish its old direction of the Crusade, and of the complete failure of its attempt. Until the accession of Innocent III. in 1198 the lay motive was supreme; and its representative was Henry VI.—the greatest politician of his day, and in many ways the greatest emperor since Charlemagne. In 1195 Amalric, the brother of Guy de Lusignan, and his successor in Cyprus, sought the title of king from Henry and did homage; and at the same time Leo of Lesser Armenia, in order to escape from dependence on the Eastern empire, took the same course. Henry thus gained a basis in the Levant; while the death of Saladin in 1193, followed by a civil war between his brother, Malik-al-Adil, and his sons for the possession of his dominions, weakened the position of the Mahommedans. As emperor, Henry was eager to resume the imperial Crusade which had been stopped by his father's death; while both as Frederick's successor and as the king of the Latin Kingdom of Jerusalem, Henry was the rival of a great power. Above all, the position of the crusaders was a question to be settled with the rulers of Constantinople. The project of a Crusade and of an attack on Constantinople wove themselves into a single thread, in a way which very definitely anticipates the Fourth Crusade of 1202-1204. In 1195 Henry took the cross; some time before, he had already sent to Isaac Angelus to demand compensation for the injuries done to Frederick I., along with the cession of all territories ever conquered by the Norman kings of Sicily, and a fleet to co-operate with the new Crusade. In the same year, however, Isaac was dethroned by his brother, Alexius III.; but Henry married Isaac's daughter Irene to his brother, Philip of Swabia, and thus attempted to give the Hohenstaufen a new title and a valid claim against the usurper Alexius. Thus armed he pushed forward the preparations for the Crusade in Germany—a Crusade whose first object would have been an attack on Alexius III.; but in the middle of his preparations he died in Sicily in the autumn of 1197, and the Crusade collapsed. Some results were, however, achieved by a body of German crusaders which had sailed in advance of Henry's army to Acre. In 1205, after the death of Constantine of Golden Cyprus succeeded Henry of Champagne, who died in 1197, as king of Jerusalem, and, as a result of the death of the emperor thus became ruler in the Holy Land; while the Teutonic order, which had begun as a hospital during the siege of Acre (1190-1191), now received its organization. Some of the coast towns, too, were recovered by the German crusaders, especially Beirut; and in 1208 the new king Amalric II. was able to make a truce with Malik-al-Adil for the next five years.

"The true heir of Henry VI.," Ranke has said, "is Innocent III.," and nowhere is this more true than in respect of the crusading movement. Throughout the course of his crowded and magnificent pontificate, Innocent III. made the Crusade his ultimate object, and attempted to bring it back to its old religious basis and under its old papal direction. By the spring of 1200, owing to Innocent's exertions, a new Crusade was in full progress, especially in France, where Fulke of Neullieu played the part once played by Peter the Hermit. Like the First Crusade, the Fourth Crusade also—in its personnel, but not its direction—was a French enterprise; and its leading members were French nobles, like Theobald of Champagne (who was chosen leader of the Crusade), Philip of Swabia, and Henry of Sicily (the former kept for himself Constantineopolis, and the count of Blois). The object, which these three original chiefs of the Fourth Crusade proposed to themselves, was Egypt. Since 1163 the importance of acquiring Egypt had, as we have seen, been definitely understood, and

---

1 The Crusades in their course established a number of new states or kingdoms. The First Crusade established the kingdom of Jerusalem (1100); the Third, the kingdom of Cyprus (1195); the Fourth, the Latin empire of Constantinople (1204); while the long Crusade of the Teutonic knights on the coast of the Baltic led to the rise of the great Hanseatic League. The kingdom of Armenia, established in 1195, may also be regarded as a result of the Crusades. The history of the kingdom of Jerusalem is part of the history of the Crusades: the history of the other kingdoms or states (of which the most important was that of the Crusade) of the Latin empire of Constantinople, the history of Cyprus is particularly important—and for two reasons. In the first place, Cyprus was a natural and excellent basis of operations; it sent provisions to the crusaders in 1191, and again at the siege of Acre, in 1191; and all its provisions were supplied as a species of tribute. But the monarch was stronger in Cyprus than in Jerusalem; the seigneurs were appointed by the emperor, and its capital, Famagusta, was an important centre of trade after the loss of the coast-towns in the kingdom of Jerusalem. In 1205 the island was acquired by Venice, which had maintained the last Byzantine buffer in front of the capital of the old kingdom. Till 1289 the kingdom of Cyprus survived as an independent monarchy, and its capital, Famagusta, was an important centre of trade after the loss of the coast-towns in the kingdom of Jerusalem. In 1205 it was acquired by Venice, which claimed the island on the death of the last king, having adopted his widow (a Venetian lady named Catarina Cornaro) as a daughter of the republic. On the history of Cyprus, see Stubbs, Lectures on Medieval and Modern Law (1890), 199-211; and, for the history of Venice, the history of the Hohenstaufen, which had maintained the Teutonic States on the island. The Armenians in the south-east of Asia Minor borrowed feudal institutions from the Franks and the feudal vocabulary itself. The kingdom was invaded in a swarming way by the Turks in the early part of the 11th century, and it allied itself with the Mongols and fought against the Mamelukes, whom, however, it finally succumbed in 1296.

2 The kingdom of Jerusalem is thus from 1192 to its final fall a strip of land, through which it is the object of kings and crusaders to annex Jerusalem and a line of communication connecting it with the coast. This was practically the aim of Richard I.'s revolutions; and this was what Frederick II. for a time secured.

3 M. Luchaire, in the volume of his biography of Innocent III. called La Question d'Orient, shows how, in spite of the pope, the Fourth Crusade was in its very beginnings a lay enterprise. The crusading barons of France chose their own leader, and determined their own route, without consulting Innocent.
in the summer of 1102 Richard I. had been advised by his counsellors that Cairo and not Jerusalem was the true point of attack; while in 1200 there was the additional reason for preferring an attack on Egypt, that the truce in the Holy Land between Amalric II. and Malik-al-Adil had still three years to run. It is Egypt therefore—to which, it must be remembered, the centre of Mahomedan power had now been virtually shifted, and to which motives of trade impelled the Italian towns (since from it they could easily reach the Red Sea, and the commerce of the Indian Ocean)—it is Egypt which is henceforth the normal goal of the Crusades. This is one of the many facts which differentiate the Crusades of the 13th from those of the preceding century. But, with Syria in the hands of the Mahomedans, the attack on Egypt must necessarily be directed by sea; and thus the Crusade henceforth becomes—what the Third Crusade, here as elsewhere the turning-point in crusading history, had already in part been—a maritime enterprise. Accordingly, early in 1201, envoys from each of the three chiefs of the Fourth Crusade (among whom was Villehardouin, the historian of the Crusade) came to Venice to negotiate for a passage to Egypt. An agreement was made between the doge and the envoys, by which transport and active help were to be given by Venice in return for 85,000 marks and the cession of half of the conquests made by the crusaders. But the Fourth Crusade was not to be plain sailing to Egypt. It became involved in a maelstrom of conflicting political motives, by which it was swept to Constantinople. Here we must distinguish between cause and occasion. There were three great causes which made for an attack on Constantinople by the West. There was first of all the old crusading grudge against the Eastern empire, and its fatal policy of regarding the whole of the Levant as its lost provinces, to be restored as soon as conquered, or at any rate held in fee, by the Western crusaders—a policy which led the Eastern emperors either to give niggardly aid or to pursue obstructive tactics, and caused them to be blamed for the failure of the Crusades in 1101, and 1149, and in 1190. It is significant of the final result of these things that already in 1147 Roger of Sicily, engaged in war with Manuel, had proposed the sea-philos of the Second Crusade, perhaps with some intention of diverting it against Constantinople; and in the winter of 1189-1190 Barbarossa, as we have seen, had actually thought and spoken of an attack on Constantinople. In the second place, there was the commercial grudge of Venice, which had only been given large privileges by the Eastern empire to desire still larger, and had, moreover, been annoyed not only by alterations or revocations of those privileges, such as the usurper Alexius III. had but recently attempted, but also by the temporary destruction of their colony in Constantinople in 1171. Lastly, and perhaps most of all, there is the old Norman blood-feud with Constantinople, as old as the old Norse seeking for Micklegarth, and keen and deadly ever since the Norman conquest of the Greek themes in South Italy (1041 onwards). The heirs of the Norman kings were the Hohenstaufen; and we have already seen Henry VI. planning a Crusade which would primarily have been directed against Constantinople. It is on this Hohenstaufen policy which becomes the primary occasion of the diversion of the Fourth Crusade. Philip of Swabia, engaged in a struggle with the papacy, found Innocent III. planning a Guelph Crusade, which should be under the direction of the church; and to this Guelph project he opposed the Ghibelline plan of Henry VI., with such success that he transmuted the Fourth Crusade into a political expedition against Constantinople. To such a policy of transmutation he was urged by two things. On the one hand, the death of the count of Champagne (May 1201) had induced the crusaders to elect as their leader Boniface of Montferrat, the brother of Conrad; and Boniface was the cousin of Philip, and interested in Constantinople, where not only Conrad, but another brother as well, had served, and suffered for their service at the hands of their masters. On the other hand, Alexius, the son of the dethroned Isaac Angelus, was related to Philip through his marriage with Irene; and Alexius had escaped to the German court to urge the restoration of his father. On Christmas day 1201, Philip, Alexius and Boniface all met at Hagenaü1 and formulated (one may suppose) a plan for the diversion of the Crusade. Events played into their hands. When the crusaders gathered at Venice in the autumn of 1202, it was found impossible to get together the 85,000 marks promised to Venice. The Venetians, already, perhaps, indoctrinated in the Hohenstaufen plan—indicated to the leaders a way of meeting the difficulty: they had only to lend their services to the republic for certain ends which it desired to compass, and the debt was settled. The conquest of Zara, a port on the Adriatic claimed by the Venetians from the king of Hungary, was the only object overtly mentioned; but the idea of the expedition to Constantinople was in the air, and the crusaders knew what was ultimately expected. It took time and effort to bring them round to the diversion: the pope—naturally enough—set his face sternly against the project, the more as the usurper, Alexius III., was in negotiation with him in order to win his support against the Hohenstaufen, and Innocent hoped to find, as Alexius promised, a support and a reinforcement for the Crusade in an alliance with the Greek empire. But they came round none the less, in spite of Innocent's efforts. The pope forbade any Crusade in October 1202 Zara was taken; and at Zara the final decision was taken. Alexius joined the army; and in spite of the opposition of stern crusaders like Simon de Montfort, who sailed away ultimately to Palestine, he succeeded by large promises in inducing the army to follow in his train to Constantinople. By the middle of July 1203 Constantinople was reached, the usurper was in flight, and Isaac Angelus was restored to his throne. But when the time came for Alexius to fulfil his promises, the difficulty which had arisen at Venice in the autumn of 1202 repeated itself. Alexius's resources were insufficient, and he had to beg the crusaders to wait at Constantinople for a year in order that he might have time. They waited; but the closer contact of a prolonged stay only brought into fuller play the essential antipathy of the Greek and the Latin. Continual friction developed at last into the open fire of war; and in March 1204 the crusaders resolved to storm Constantinople, and to divide among themselves the Eastern empire. In April Constantinople was captured; in May Baldwin of Flanders became the first Latin emperor of Constantinople. Venice had her hopes rewarded. A Venetian, Thomas Morosini, became patriarch; and the doge of Venice added "a quarter and a half" of the Eastern empire—chiefly the coasts and the islands—to the sphere of his sway. If Venetian cupidity had not originally deflected the Crusade (and it was the view of contemporary writers that Venice had committed her first treason against Christianity by diverting the Crusade from Egypt in order to get commercial concessions from Malik-al-Adil,2 yet it had at any rate profited exceedingly from that defection; and the Hohenstaufen and their protégé Alexius only reaped dust and ashes. For, however Ghibelline might be the original intention, the result was not commensurate with the subtlety of the design, and the power of the pope was rather increased than diminished by the event of the Crusade. The crusaders appealed to Innocent to ratify the subjugation of a schismatic people, and the union of the Eastern and Western Churches; and Innocent, dazzled by the magic of the fait accompli, not unwillingly acquiesced. He might soothe himself thinking that the basis for the Crusade, which he had hoped to find in Alexius III., was still more securely offered by Baldwin; he could not but feel with pride that he had become "as it were pope and apostolicus of a second world." Yet the result of the Fourth Crusade was on the whole disastrous both for the papacy and for the crusading movement. The pope had been forced to

1 As a matter of fact, there is some doubt whether Alexius arrived in Germany before the spring of 1202. But there seems to be little doubt of Philip's complicity in the diversion of the Fourth Crusade to Constantinople (cf. M. Luchaire, La Question d'Orient, pp. 84-86).

2 It is true that in 1208 Venice received commercial concessions from the court of Cairo. But this ex post facto argument is the sole proof of this view; and it is quite insufficient to prove the accusation. Venice is not the primary agent in the deflection of the Fourth Crusade.
see the helm of the Crusades wrested from his grasp; and the Albignian Crusade against the heretics of southern France was soon afterwards to show that the example could be followed, and that the land-hunger of the north French baronage could exploit a Crusade as successfully as ever did Hohenstaufen policy leagued with Venetian cupidity. The Crusade lost its élan when it became a move in a political game. If the Third Crusade had been directed by the lay power towards the true spiritual end of all Crusades, the Fourth was directed by the lay power to its own lay ends; and the political and commercial motives, which were deeply implicit even in the First Crusade, had now become dominantly explicit. In a simpler and more immediate sense, the capture of Constantinople was detrimental to the movement from which it sprang. The precarious empire which had been founded in 1204 drained away all the vigorous adventurers of the West for its support for many years to come, and the Holy Land was starved to feed a land less holy, but equally greedy of men.¹ No basis for the Crusades was ever to be found in the Latin empire of the East; and Innocent, after vainly hoping for the new Crusade which was to emerge from Constantinople, was by 1208 compelled to return to the old idea of a Crusade proceeding simply and immediately from the West to the East.

The Fifth Crusade, 1218-1221.—The glow and the glamour of the Crusades disappear save for the pathetic sunset splendours of St Louis, as Dandolo dies, and gallant Villehardouin drops his pen. But before St Louis sailed for Damietta there intervened the miserable failure of one Crusade, and the secular and diplomatic success of another. The Fifth Crusade is the last which is started in that pontificate of Crusades—the pontificate of Innocent III. It owed its origin to his feverish zeal for the recovery of Jerusalem, rather than to any pressing need in the Holy Land. Here there reigned, during the forty years of the loss of Jerusalem, an almost unbroken peace. Malik-al-Adil, the brother of Saladin, who had by 1200 succeeded to his brother’s possessions not only in Egypt but also in Syria, and he granted the Christians many favours, signed a truce (1198-1203, 1204-1219, 1211-1217). While the Holy Land was thus at peace, crusaders were also being drawn elsewhere by the needs of the Latin empire of Constantinople, or the attractions of the Albignian Crusade.² But Innocent could never consent to forget Jerusalem, as long as his right hand retained its cunning. The pathos of the Children’s Crusade of 1212 only served him to fresh efforts. A shepherd boy named Stephen had appeared in France, and had induced thousands to follow his guidance: with his boyish army he rode on a wagon southward to Marseilles, promising to lead his followers dry-shod through the seas. In Germany a child from Cologne, named Nicolas, gathered some 20,000 young crusaders by the like promises, and led them into Italy. Stephen’s army was kidnapped by slave-dealers and sold into Egypt; while Nicolas’s expedition left nothing behind it but an after-echo in the legend of the Pied Piper of Hamelin. But for Innocent these outbursts of the revivalist element, which always accompanied the Crusades, had their moral: “the very children put us to shame,” he wrote; “while we sleep

¹ Already under Innocent III, the benefits of the Crusade were promised to those who went to the assistance of the Latin empire of the East.

² In 1204 Innocent excommunicated Raymund VI. of Toulouse on account of the murder of a papal legate who was attempting to suppress Manicheism, and offered all Catholics the right to occupy and guard his territories. Thus was begun the First Crusade against heretics, but Raymond at once submitted to the pope, but the Crusade continued none the less, because, as Luchaire says, “the barrenness of the north and centre of France had finished their preparations,” and were resolved to annex the rich lands of the south. In this way land-hunger exploited the Albignians, as political and commercial motives, and not political motives, exploit the modern crusader, as in the latter, Innocent had reluctantly consent to the results of the secular motives which had infected a spiritual enterprise. The Albignian Crusades, however, belong to French history; and it can only be noted here that their ultimate result was the absorption of the fertile lands, and the extinction of the peculiar civilization, of southern France by the northern monarchy. (See the article Albignians.)
commercial reasons for wishing to establish a strong position in Egypt, and to the Templars and Hospitallers, who did not feel satisfied by the terms offered by the sultan, because he wished to retain in his hands the two fortresses of Krak and Monreal. 

The Crusade was launched on 29 June 1228, and the Fifth Crusade had failed; but the circumstances under which it took place and the means by which it was conducted made its success still more disastrous than the failure of 1221. The last Crusade had, after all, been under papal control: if Richard I. had directed the Third Crusade, and the policy of the Hohenstaufen and the Venetians had directed the Fourth, it was a papal legate who had steered the Fifth to its ultimate fate. The Crusade of Frederick II. in 1228–1229 finds its analogy in the projected Crusade of Henry VI.; it is essentially lay. It is unique in the annals of the Crusades. Alone of all Crusades (though the Fourth Crusade offers some analogy) it was not blessed but cursed by the papacy: alone of all the Crusades it was conducted without a single act of hostility against the Mahomedan. St Louis, the true type of the religious crusader, once said that a layman ought only to argue with a blasphemer against Christian law by running his sword into the bowels of the blasphemer as far as it would go:1 Frederick II. talked amicably with all unbelievers, and by his peace negotiations the recovery of Jerusalem, for which men had vainly striven with the sword for the forty years since 1187. It was in 1215 that the leader of this strange Crusade had first taken the vow; it was twelve years afterwards that he finally attempted to carry the vow into effective execution. Again and again he had excused himself to the pope, and had been excused by the pope, because the exigencies of his policy in Germany or Sicily tied his hands. After the failure of the Fifth Crusade—for which these delays were in part responsible—Honourius III. had attempted to bind him more intimately to the Holy Land by arranging a marriage with Isabella, the daughter of John of Brienne, and the heiress of the kingdom of Jerusalem. In 1225 Frederick married Isabella, and immediately after the marriage he assumed the title of king in right of his wife, and exacted homage from the vassals of the kingdom.2 It was thus as king of Jerusalem that Frederick began his Crusade in the autumn of 1227. Scarcely, however, had he sailed from Brindisi when he fell sick of a fever which had been raging for some time among the ranks of his army, while they waited for the crossing. He sailed back to Otranto in order to recover his health, but the new pope, Gregory IX., launched in hot anger the bolt of excommunication, in the belief that Frederick was malingering once more. None the less the emperor sailed on his Crusade in the summer of 1228, affording to astonished Europe the spectacle of an excommunicated crusader, and leaving its territories to be invaded by papal soldiers, whom Gregory IX. professed to regard as crusaders against the Christian king, and for whom he accordingly levied a tithe from the churches of Europe. The paradox of Frederick’s Crusade is indeed astonishing. Here was a crusader against whom a Crusade was proclaimed in his own territories; and when he arrived in the Holy Land he found little obedience and many insults from all but his own immediate followers. Yet by adroit use of his powers of diplomacy, and by playing upon the dissensions which raged between the descendants of Saladin’s brother (Malik-al-Adil), he was able, without striking a blow, to conclude a treaty with the sultan of Egypt which gave him all that Richard I. had vainly attempted to secure by arduous fighting and patient negotiations. By the treaty of the 18th of February 1229, which was to last for ten years, the sultan conceded to Frederick, in addition to the coast towns already in the possession of the Christians, Nazareth, Bethlehem and Jerusalem, with a strip of territory connecting Jerusalem with the port of Acre. As king of Jerusalem Frederick was now able to enter his capital: as one under excommunication, he had to see an interdict immediately fall on the city, and it was with his own hands—for no churchman could perform the office—that he had to take his crown from the altar of the church of the Holy Sepulchre, and crown himself king of his new kingdom. He stayed in the Holy Land little more than a month after his coronation; and leaving in May he soon overcame the papal armies in Italy, and secured absolution from Gregory IX. (August 1229). By his treaty with the sultan he had secured for Christianity the last fifteen years of its possession of Jerusalem (1229–1244): no man since Frederick II. has ever recovered the holy places for the religion which holds them most holy. Yet the church might ask, with some justice, whether the means he had used were excused by the end which he had attained. After all, there was nothing of the holy war about the Sixth Crusade: there was simply bucklering, as in an Eastern bazaar, between a free-thinking, semi-oriental king of Sicily and an Egyptian sultan. It was indeed in the spirit of a king of Sicily, and not in the spirit—though it was in the role—of a king of Jerusalem, that Frederick had acted. It was from his Sicilian predecessors, who had made trade treaties with Egypt, that he had learned to make even the Crusade a matter of treaty. The Norman line of Sicilian kings might be extinct; their policy lived after them in their Hohenstaufen successors, and that policy, as it had helped to divert the Fourth Crusade to the old Norman objective of Constantinople, helped still more to give the Sixth Crusade its secular, diplomatic, non-religious aspect.

Forty years of struggle ended in fifteen years’ possession of Jerusalem. During those fifteen years the kingdom of Jerusalem was agitated by a struggle between the native barons, championing the principle that sovereignty resided in the collective baronage, and taking their stand on the assizes, and Frederick II., claiming sovereignty for himself, and opposing to the assizes the feudal law of Sicily. It is a struggle between the king and the haute cour: it is a struggle between the aristocratic feudalism of the Franks and the monarchical feudalism of the Normans. Already in Cyprus, in the summer of 1228, Frederick II. had insisted on the right of wardship which he enjoyed as overlord of the island,3 and he had appointed a commission of five barons to exercise his rights. In 1229 this commission was overthrown by John of Ibelin, lord of Beirut, against whom it had taken proceedings. John of Beirut, like many of the Cypriot barons, was also a baron of the kingdom of Jerusalem; and resistance in the one kingdom could only produce difficulties in the other. Difficulties quickly arose when Frederick, in 1231, sent Marshal Richard to Syria as his legate. This in itself was a serious matter; according to the assizes, the barons maintained, the king must either personally reside in the kingdom, or, in the event of his absence, be replaced by a regency. The position became more difficult, when the legate took steps against John of Beirut without any authorization from the high court. A gild was formed at Acre—the gild of St Adrian—which, if nominally religious in its origin, soon came to represent the political opposition to Frederick, as was significantly proved by its reception of the rebellious John of Beirut as a member (1232). The opposition was successful: by 1233 Frederick had lost all hold on Cyprus, and only retained Tyre in his own kingdom of Jerusalem. In 1236 he had to promise to recognize fully the laws of the kingdom: and when, in 1239, he was again excommunicated by Gregory IX., and a new quarrel of papacy and empire began, he soon lost the last vestiges of his power. Till 1243 the party of Frederick had been successful in retaining Tyre, and the baronial demand for a regency had remained without effect; but in that year the opposition, headed by the great family of Ibelin, succeeded, under cover of asserting the rights of Alice of Cyprus to the regency, in securing possession of Tyre, and the kingdom of Jerusalem thus fell back into the power of the baronage. The very next year (1244) Jerusalem was finally and for ever lost. Its loss was the natural corollary of these dissensions. The king of Jerusalem was now treated as a mere vassal of the great barons, and he died in 1250, without having been able to recover the holy city of Acre, which was a constant object of his hope and ambition.

1Joinville, ch. x.
2John of Brienne had only ruled in right of his wife Mary. On her death (1225) John might be regarded as only ruling "by the courtesy of the kingdom," until her daughter Isabella was married, when the husband would succeed. That, at any rate, was the view Frederick II. took.

3Amalric I. of Cyprus had done homage to Henry VI., from whom he had received the title of king (1195).
treaty of Frederick with Malik-al-Kamil (d. 1238) had now expired, and new succours and new measures were needed for the Holy Land. Theobald of Champagne, who had taken credit as early as 1230, and in 1235 he sailed for Acre in spite of the express prohibition of the pope, who, having quarrelled with Frederick II., was eager to divert any succour from Jerusalem itself, so long as Jerusalem belonged to his enemy. Theobald was followed (1240-1241) by Richard of Cornwall, the brother of Henry III., who, like his predecessor, had to sail in the teeth of papal prohibitions; but neither of the two achieved any permanent result, except the fortification of Ascalon. It was, however, by their own folly that the Franks lost Jerusalem in 1244. They consented to ally themselves with the ruler of Damascus against the sultan of Egypt; but in the battle of Gaza they were deserted by their allies and heavily defeated by the Chorasmians (Khwarizmians), who knew unexpected victory. Frederick again took the cross, and in the battle of the Fifth Crusade he was defeated. His retinue became a rout. St Louis was captured, and a treaty was made by which he had to consent to evacuate Damietta and pay a ransom of 500,000 pieces of gold. Eventually St Louis was released on renouncing Damietta and paying one-half of his ransom, and by the middle of May 1250 he reached Acre, having abandoned the Egyptian expedition. For the next four years he stayed in the Holy Land, seeking to do what he could for the establishing of the kingdom of Jerusalem. He was able to do but little. The struggle of papacy and empire paralysed Europe, and even in France itself there were few ready to answer the calls for help which St Louis sent home from Acre. The one answer was the Shepherds’ Crusade, or Crusade of the Crusaders—"a religious Jacquerie," as it has been called by Dean Milman. It had some of the features of the Children’s Crusade of 1212. That, too, had begun with a shepherd boy: the leader of the Crusaders, like the leader of the children, promised to lead his followers dry-shod through the seas; and tradition even said that this leader, "the master of Hungary," as he was called, was the Stephen of the Children’s Crusade. But the anti-clerical feeling and action of the Shepherds was new and ominous; and moved by its enormities the government suppressed the movement ruthlessly. None came to the aid of St Louis. Theobald had died in 1254, on the death of his brother Blanche, the regent, he had to return to France. The final collapse of the kingdom of Jerusalem had been really determined by the battle of Gaza in 1244, and by the deposition of the Ayyubite dynasty by the Mamelukes. The Ayyubites had always been, on the whole, chivalrous and tolerant: Saladin and his successors, Malik-al-Adil and Malik-al-Kamil, had none of them shown an implacable enmity to the Christians. The Mamelukes, who are analogous to the janissaries of the Ottoman Turks, were made of stern and more fanatical stuff; and the Chorasmians, the greatest of these Mamelukes, who had commanded at Gaza in 1244, had been one of the leaders in 1250, and was destined to become sultan in 1260, was the sternest and most fanatical of them all. The Christians were, however, able to maintain a footing in Syria for forty years after St Louis’ departure, not by reason of their own strength, but owing to two powers which checked the advance of the Mamelukes. The first of these was Damascus. The kingdom of Jerusalem, as we have seen, had profited by the alliance of Damascus as early as 1130, when the death of the last member of the house of Nureddin in Damascus and Saladin in Egypt had still for a time preserved the kingdom (from 1171 onwards). Saladin had united Egypt and Alexandria; but after his death dissensions broke out among the members of his family, which more than once led to wars between Damascus and Cairo. It has already been noticed that such a war between the sons of Malik-al-Adil accounts in large

Turanshah, deposed 1250, and succeeded by the Mameluke Aibek.
measure for the success of the Sixth Crusade; and it has been seen that the battle of Gaza was an act in the long drama of strife between Egypt and northern Syria. The revolution in Egypt in 1250 separated Damascus from Cairo more trenchantly than they had ever been separated since 1177: while a Mameluke ruled in Cairo, Malik-al-Nasir of Aleppo was elected as sultan by the emirs of Damascus. But an entirely new and far more important factor in the affairs of the Levant was the extension of the empire of the Mongols during the 13th century. That empire had been founded by Jenghiz Khan in the first quarter of the century; it stretched from Peking on the east to the Euphrates and the Dnieper on the west. Two things gave the Mongols an influence on the history of the Holy Land and the fate of the Crusades. In the first place, the south-western division of the empire, comprising Persia and Armenia, and governed about 1250 by the Khan Hulaku or Hulagü, was inevitably brought into relations, which were naturally hostile, with the Mahommedan powers of Syria and Egypt. In the second place, the Mongols of the 13th century were not as yet, in any great numbers, Mahommedans; the official religion was “Shamanism,” but in the Mongol army there were many Christians, the results of early Nestorian missions to the far East.

This last fact in particular caused the pope to think of an alliance with the great Khan “Frater John,” who shewed an interest in recovering Jerusalem and the final conversion to Christianity of the whole continent of Asia. The Crusades thus widen out, towards their close, into a general scheme for the christianization of all the known world.

About 1220 James of Vitry was already hoping that 4000 knights would, with the assistance of the Mongols, recover Jerusalem; but it is in 1245 that the first definite sign of an alliance with the Mongols appears. In that year Innocent IV. sent a Franciscan friar, Johannes de Piana Carpini, to the Mongols of southern Russia, and despatched a Dominican mission to Persia. Nothing came of either of these missions; but through them Europe first began to know the interior of Asia, for Carpini was conducted by the Mongols as far as Karakorum, the capital of the great khan, on the borders of China. Again in 1252 St Louis (who had already begun to negotiate with the Mongols in the winter of 1248-1249) sent the friar William of Rubruquis to the court of the great khan; but again nothing came of the mission save an increase of geographical knowledge. It was in the year 1260 when it seemed likely that any results definite, effecting the course of the Crusades would result from the action of the Mongols. In that year Hulagu, the khan of Persia, invaded Syria and captured Damascus. He was, in general, a Christian named Kibogha, marched southwards to attack the Mamelukes of Egypt, but he was beaten by Bihars (who in the same year became sultan of Egypt), and Damascus fell into the hands of the Mamelukes. Once more, in spite of Mongol intervention, Damascus and Cairo were united, as they had been united in the hands of Saladin; once more they were united in the hands of a devout Mahommadedan, who was resolved to expirate the Christians from Syria.

While these things were taking place around them, the Christians of the kingdom of Jerusalem only hastened their own fall by internal dissensions which repeated the history of the period preceding 1187. In part the war of Gucph and Ghibelline fought itself out in the East; and while one party demanded a regency, as in 1243, another argued for the recognition of Conrad, the son of Frederick II., as king. In part, again, a commercial war raged between Venice and Genoa, which attracted into its orbit all the various feuds and animosities of the Levant (1257). Beaten in that war by the Genoese avenged themselves for their defeat by an alliance with the Palaiologoi, which led to the fall of Constantinople by the Latins (1261), and to the collapse of the Latin empire after sixty years of infirm and precarious existence. On a kingdom thus divided

1 Though Europe indulged in dreams of Mongol aid, the eventual results of the extension of the Mongol Empire were prejudicial to the Latin East. The sultans of Egypt were stirred to fresh activity by the attacks of the Mongols; and as Syria became the battle-ground of the two, the Latin principalities of Syria were fated to fall as the price of victory to one or other of the combatants.

2 Of the four Latin principalities of the East, Edessa was the first to fall, being extinguished between 1144 and 1150. Antioch fell in 1268; Tripoli in 1289; and the kingdom itself may be said to end with the capture of Acre, 1291.

3 Michael Palaeologus had actually appealed to Louis IX. against Charles of Anjou, who in 1270 had actively begun preparations for the attack on Constantinople.
CRUSADES

545

with the Mongols, but achieving no permanent results. He returned home at the end of 1372, the last of the western crusaders; and thus all the attempts of St Louis and Charles of Anjou, of James of Aragon and Edward of England left Bibars still in possession of all his conquests.

Two projects of Crusades were started before the final expulsion of the Latins from Syria. In 1274, at the council of Lyons, Gregory X., who had been the companion of Edward in the Holy Land, preached the Crusade to an assembly which contained envoys from the Mongol khan and Michael Palaeologus as well as many western princes. All the princes of western Europe took the cross; not only so, but Gregory was successful in uniting the Eastern and Western churches for the moment, and in securing for the new Crusade the aid of the Palaeologoi, now thoroughly alarmed by the plans of Charles of Anjou. Thus was a papal Crusade begun, backed by an alliance with Constantinople, and thus were the plans of Charles of Anjou temporarily thwarted. But in 1276 Gregory X. died, and all his plans died with him; there was to be no union of the monarchs of the West with the emperor of the East in a common Crusade. Charles was able to resume his plans. In 1277 Mary of Antioch ceded to him her claims, and he was able to establish himself in Acre; in 1278 he took possession of the principality of Achaea. With these bases at his disposal he began to prepare a new Crusade, to be directed primarily (like that of Henry VI. in 1197, and like his own projected Crusade of 1270) against Constantinople. Once more his plans were crossed finally and fatally: the Sicilian Vespers, and the coronation of Peter of Aragon as Sicilian king (1282), gave him troubles at home which occupied him for the rest of his days. This was the last serious attempt at a Crusade on behalf of the dying kingdom of Jerusalem which was made in the West; and its collapse was quickly followed by the final extinction of the kingdom. A precarious peace had reigned in the Holy Land since 1272, when Bibars had granted a truce of ten years; but the fall of the great power of Charles of Anjou set free Kalâ‘un the successor of Bibars' son (who reigned little more than two years), to complete the work of the great sultan. In 1289 Kalâ‘un took Tripoli, and the county of Tripoli was extinguished; in 1290 he died while preparing to besiege Acre, which was captured after a brave defence by his son and successor Khalîl in 1291. Thus the kingdom of Jerusalem came to an end. The Franks evacuated Syria altogether, leaving behind them only the ruins of their castles to bear witness, to this very day, of the Crusades they had waged and the kingdom they had founded and lost.

9. The Ghost of the Crusades.—The loss of Acre failed to stimulate the powers of Europe to any new effort. France, always the natural home of the Crusades, was too fully occupied first with England and then by a struggle with the papacy, to turn her energies towards the East. But it is often the case that theory develops as practice fails; and as the theory of the Holy Roman Empire was never more vigorous than in the days of its decadence, so it was with the Crusades. Particularly in the first quarter of the 14th century, writers were busy in explaining the causes of the failures of past Crusades, and in laying down the lines along which a new Crusade must proceed. Several causes are recognized by these writers as accounting for the failure of the Crusades. Some of them lay the blame on the papacy; and it is true that the papacy had contributed towards the decay of the Crusades when it had allowed its own particular interests to overbear the general welfare of Christianity, and had dignified with the name and the benefits of a Crusade its own political war against the Hohenstaufen in Germany. In fact the princes of Europe were for the ruin of the Crusades; they too had preferred their own national or dynastic interests to the cause of a common Christianity. They had indeed, as has been already noticed, done even more; they had used the name of Crusade, from the days of Henry VI. onwards, as a cover and an excuse for secular ambitions of their own; and in this way they had certainly helped, in very large measure, to discourage the old religious zeal for the Holy War. Other writers, again, blame the commercial cupidty of the Italian towns; of what avail, they asked with no little justice, was the Crusade, when Venice and Genoa destroyed the naval bases necessary for its success by their internecine quarrels in the Levant (as in 1257), or—still worse—entered into commercial treaties with the common enemy against whom the Crusades were directed? On the very eve of the Fifth Crusade, Venice had concluded a commercial treaty with Malik-al-Kamil of Egypt; just before the fall of Acre the Genoese, the king of Aragon and the king of Sicily had all concluded advantageous treaties with the sultan Kalâ‘un. A fourth cause, on which many writers dwelt, particularly at the time when the suppression of the Templars was in question, was the dissensions between the two orders of Templars and Hospitallers, and the selfish policy of merely pursuing their own interest which was followed by both in common. But one might enumerate ad infinitum the causes of the failure of the Crusades. It is simplest, as it is truest, to say that the Crusades did not fail—they simply ceased; and they ceased because they were no longer in joint with the times. The moral character of Europe in 1300 was no longer the moral character of Europe in 1100; and the Crusades, which had been the active and objective embodiment of the other worldly Europe of 1100, were alien to the secular, legal, scholastic Europe of 1300. While Edward I. was seeking to found a united kingdom in Great Britain; while the Habsburgs were entrenching themselves in Austria; above all, while Philippe le Bel and his legists were consolidating the French monarchy on an absolutist basis, there could be little thought of the holy war. These were hard-headed men of affairs—men who would not lightly embark on joyous ventures, or seek for an ideal San Graal; nor were the popes, doomed to the Babylonian captivity for seventy long years at Avignon, able to call down the spark from on high which should consume all earthly ambitions in one great act of sacriifice.

But it is long before the death of any institution is recognized; and it was inevitable that men should busy themselves in trying to rekindle the dead embers into new life. Pierre Dubois, in a pamphlet "De recuperatione Sanctae Terrae," addressed to Edward I. in 1307, advocates a general council of Europe to maintain peace and prevent the dissensions which—as, for instance, in 1192—had helped to cause the failure of past Crusades. Along with this advocacy of internationalism goes a plea for the disendowment of the Church, in order to provide an adequate financial basis for the future Crusade. Other proposals, made by men well acquainted with the East, are more definitely practical and less political in their intention. A blockade of Egypt by an international fleet, an alliance with the Mongols, the union of the two great orders—these are the three staple heads of those proposals. Something, indeed, was attempted, if little was actually done, under each of these three heads. The plan of an international fleet to coerce the Mahomedan is even to this day ineffective; but the Hospitallers, who acquired a new basis by the conquest of Rhodes in 1310, used their fleet to enforce a partial and, on the whole, ineffective blockade of the coast of the Levant. The union of the two orders, already suggested at the council of Lyons in 1245, was nominally achieved by the council of Vienne in 1311; but the so-called "union" was in reality the suppression of the Templars, and the confiscation of all their resources by the cupidty of Philippe le Bel. The alliance with the Mongols remained, from the first to the last, something of a chimera; and the last visionary hope vanished when the Mongols finally embraced Mahommedanism, as, by the end of the 14th century, they were almost universally done. A more isolated enterprise of the character of a Crusade, but hardly serious enough to be dignified by that name, recur during the 14th century. The French kings are all crusaders—in name—until the beginning of the Hundred Years' War; but the only crusader who ever carried war in Palestine and sought to shake the hold of the Mamelukes on the Holy Land was Peter I., king of Cyprus from 1350 to 1360. Peter founded the order of the Sword for the delivery of Jerusalem; and instigated by his chancellor, P. de Mézières (one of the last of
the theorists who speculated and wrote on the Crusades), he attempted to revive the old crusading spirit throughout the west of Europe. The mission which he undertook with his chancellor for this purpose (1362-1369) only procured a crop of promises or excuses from sovereigns like Edward III or the Emperor Charles IV.; and Peter was forced to begin the Crusade with such volunteers as he could collect for himself. In the autumn of 1365 he sacked Alexandria; and in 1367 he ravaged the coast of Syria, and inflicted serious damages on the sultan of Egypt. But in 1369 he was assassinated, and the last romantic figure of the Crusades died, leaving only the legacy of his memory to his chancellor de Mézières, who for nearly forty years longer continued to be the preacher of the Crusades to Europe, advocating —what always continued to be the "dream of the old pilgrim"— a new order of knights of the Passion of Christ for the recovery and defence of Jerusalem. De Mézières was the last to advocate seriously, as Peter I. was the last to attempt, a Crusade after the old fashion—an offensive war against Egypt for the recovery of the Holy Sepulchre.1 From 1350 onwards the Crusade assumes a new aspect; it becomes defensive, and it is directed against the Ottoman Turks, a tribe of Turcomans who had established themselves in the sultanate of Iconium at the end of the 13th century, dominating the crusading spirit, and those of peoples which had incurred the Mongol invasions. As early as 1368 the Ottoman Turks had begun to settle in Europe; by 1350 they had organised their terrible army of janissaries. They threatened at once the débris of the old Latin empire in Greece and the archipelago, and the relics of the Byzantine empire round Constantinople; they menaced the Hospitaliers in Rhodes and the Lusignans in Cyprus. It was natural that the popes should endeavour to form a coalition between the various Christian powers which were threatened by the Turks; and Venice, anxious to preserve her possessions in the Aegean, zealously seconded their efforts. In 1344 a Crusade, in which Venice, the Cypriots, and the Hospitaliers all joined, ended in the conquest of Smyrna; in 1345 another Crusade, led by Humbert, dauphin of Vienne, ended in failure. The Turks continued their progress; in 1363 they captured Philippopolis, and in 1365 they entered Adrianople; the whole Balkan peninsula was threatened, and even Hungary itself seemed doomed. Already in 1365 Urban VI. sought to unite the king of Hungary and the king of Cyprus, making the Sultan of the Turks his client. But in 1366 that an attempt was at last made to supplement by a land Crusade the naval Crusades of 1344 and 1345. Master of Servia and of Bulgaria, as well as of Asia Minor, the sultan Bayezid was now threatening Constantinople itself. To arrest his progress, a Crusade, preached by Boniface IX., led by John the Fearless of Burgundy, and joined chiefly by French knights, was directed down the valley of the Danube into the Balkans; but the old faults stigmatised by de Mézières, divisio et propria voluntas, were the ruin of the crusading army, and at the battle of Nicopolis it was signally defeated. Not the Western Crusades but an Eastern rival, Timur (Tamerlane), king of Transoxiana and conqueror of southern Russia and India, was destined to arrest the progress of Bayezid; and from the battle of Anora (1402) till the days of Murad II. (1422) the Ottoman power was paralysed. Under Murad, however, it rose to its old height. To meet the new danger a new union of the churches of the East and the West was attempted. As in 1077 Gregory VII. had dreamed of such a union, to be followed by a joint attack of East and West on the Seljuks, so in 1429, at the conference of Florence, a new union of the two churches was again attempted and temporarily secured, in order that a united Christendom might face the new Turkish danger.2 The logical result of the union was the Crusade of 1443. An army of cosmopolitan adventurers, led by the Cardinal Caesars, joined the forces of Wladislaus of Poland and John Hunyadi of Transylvania, and succeeded in forcing on Murad II. a truce of ten years at Szigedin in 1444. But the crusaders broke the truce, to which Caesarini had never consented; and, attempting to bottom what was already good enough, they were defeated at Varna. Here the last Crusade ended; and nine years afterwards, in 1453, Mahomet II., the successor of Murad, captured Constantinople. It was in vain that the popes sought to gather a new Crusade for its recovery; Pius II., who had vowed to join the crusade in person, only reached Ancona in 1464 to find the crusaders deserting and to die. Yet the ghost of the Crusades still lingered. It became a convention of diplomacy, designed to cover any particularly sharp piece of policy which needed some excuse; and the treaty of Granada, formed between Louis XII. and Ferdinand of Aragon for the partition of Naples in 1500, was excused as a thing necessary in the interests of the Crusades. In a more noble fashion the Crusade survived in the minds of the navigators; "Vasco da Gama, Christopher Columbus, Albuquerque, and many others dreamed, and not insincerely, that they were labouring for the deliverance of the Holy Land, and they bore the Cross on their breasts."3 "Don Henrique's scheme, it has been said, represents the final and new triumph of the Crusading spirit; and the naval campaigns against the Moslem in the Indian seas, in which it culminated, forty years after Don Henrique's death, may be described as the last Crusade.4"

10. Results of the Crusades.—In one vital respect the result of the Crusades may be written down as failure. They ended, not in the occupation of the East by the Christian West, but in the conquest of the West by the Mahommedan East. The Crusades began with the Seljuk Turk planted at Nicaea; they ended with the Ottoman Turk entrenched by the Danube. Nothing is more striking in history than the recession of Christianity in the East after the 13th century. In the 13th century the whole of Europe was Christian; part of Asia Minor still belonged to Greek Christianity, and there was a Christian kingdom in Palestine. Nor was this all. A wide missionary activity had begun in the 13th century—an activity which was the product of the Crusades and the contact with the Moslem which they brought, but which yet helped to check the Crusades, substituting as it did peaceful and spiritual conquests of souls for the violence and materialism of even a Holy War. The Holy Land itself had been contested by the Crusaders; the Turks had attacked it and attempted to convert the sultan of Egypt during the Fifth Crusade (1220); within a hundred years the little seed had grown into a great tree. A great field for missionary enterprise opened itself in the Mongol empire, in which, as has already been mentioned, there were many Christians to be found; and by 1350 this field had been so well worked that Christian missions and Christian bishops were established from Persia to Peking, and from the Dnieper to Tibet itself. But a Mahomedan reaction came, thanks in large measure to the zeal of Timur; and central Asia was lost to Christianity. Everywhere in the 15th century, in Europe and in Asia, the crescent was victorious over the cross; and Crusade and mission, whether one regards them as complementary or inimical, perished together.5

But the history of the Crusades must be viewed rather as a chapter in the history of civilization in the West itself, than as an extension of Western dominion or religion to the East. It is a chapter very difficult to write, for while on the one hand an ingenious and speculative historian may refer to the influence of the Crusades almost everything which was thought or done between 1100 and 1300, a cautious writer who seeks to find

1 Brehier, L'Eglise et l'Orient, p. 347.
2 Cambridge Modern History, i. 11. It is perhaps worth remarking that something of the old crusading spirit seems still to linger in the movement of Russia towards Constantinople.
3 While from this point of view the Crusades appear as a failure, it must not be forgotten that elsewhere than in the East the Crusades did attain some success. A Crusade won for Christianity the coast of the eastern Baltic (see Teutonic Order); and the centuries of the Spanish Crusade ended in the conquest of the whole of Spain for Christianity.
documentary evidence for every assertion may be rather inclined to attribute to that influence little or nothing. The dissolution of feudalism, the development of towns, the growth of scholasticism, all these and much more have been ascribed to the Crusades when in truth they were concomitants rather than results, or at any rate, if one part the results of the Crusades, were in far larger part the results of other things. At most, therefore, it may be admitted that the Crusades contributed to the dissolution of feudalism by putting property on the market and disturbing the validity of titles; that they aided the development of towns by vastly increasing the volume of trade; and that they furthered the growth of scholasticism by bringing the West into contact with the mind of the East. If we seek the peculiar and definite results of the Crusades, we must turn to narrower issues. In the first place, the Crusades represent the attempt of a feudal system, bound under the law of primogeniture to dispose of its younger sons. They are attempts at feudal colonization; and as such they resulted in a number of colonies —the kingdom of Jerusalem, the kingdom of Cyprus, the Latin empire of Constantinople. They resulted too in a number of "chartered companies"—that is to say, the three military orders, which, beginning as charitable societies, developed into military clubs, and developed again from military clubs into chartered companies, possessed of banks, navies and considerable territories. In the second place, as has already been noticed, the Crusades represent the attempt of Western commerce to find new and more easy routes to the wealth of the East; and in this respect they led to various results. On the one hand they led to the establishment of a new epoch in the history of the Church, and after the fall of Acre Tafamugsta, both in their day great centres of Levantine trade. On the other hand, the commodities which poured into Venice and Genoa from the East had to find a route for their diffusion through Europe. The great route was that which led from Venice over the Brenner and up the Rhine to Bruges; and this route became the long red line of municipal development, along which—in Lombardy, Germany and Flanders—the great towns of the middle ages sprang to life. Partly as a result of this trade, ever pushing its way farther east, and partly as a result of the Asiatic missions, which were themselves an accompaniment and effect of the Crusades, a third great result of the Crusades came to light in the 13th century—the discovery of the interior of Asia, and an immense accession to the sphere of geography. When one remembers that missionaries like Pino Carpini, and traders like the Venetian Polos, either penetrated by land from Acre to Peking, or circum-navigated southern Asia from Basra to Canton, one realizes that there was, about 1300, a discovery of Asia as new and tremendous as the discovery of America by Columbus two centuries later. At the same time the old knowledge of nearer Asia was immensely deepened. It has already been noticed how military reconnaissances of the routes to Egypt came to be made; but more important were the guide-books, of which a great number were written to guide the pilgrims from one sacred spot of Bible history to another. There were medieval Baedekers in abundance for the use of the annual flow of tourists, who were carried every Easter by the vessels of the Italian towns or of the Orders to visit the Holy Land and to bathe in Jordan, to gather palms, and to see the miracle of fire at the Sepulchre.

Colonization, trade, geography—these then are three things closely connected with the history of the Crusades. The development of the art of war, and the growth of a systematic taxation, are two debts which medieval Europe also owed to the Crusades. Partly by contact with the Byzantines, partly by conflict with the Mahomedans, the Franks learned new methods both of building and of attacking fortifications. The concentric castle, with its rings of walls, began to replace the old keep and bailey with their single walls, so that the Crusades brought back to the West.

1 Authors like Heeren (Versuch einer Entwicklung der Folgen der Kreuzzüge) and Micha (in the last volume of his Histoire des croisades) fall into the error of assigning all things to the Crusades. Even Prutz, in his Kulturgeschicht der Kreuzzüge, over-estimates the influence of the Crusades as a chapter in the history of civilization. He depreciates unduly the Western civilization of the early middle ages, and exalts the civilization of the Arabs; and starting from these two premises, he concludes that modern civilization is the offspring of the Crusades, which first brought East and West together.

2 It is difficult to decide how far Arabic models influenced ecclesiastical architecture in the West as a result of the Crusades. Greater freedom of moulding and the use of trifolium and cuspied may be, but need not be, explained in this way. The pointed arch owes nothing to the Arabs; it is already used in England in early Norman work. Generally, one may say that Western architecture is independent of the East.
prestige in the eyes of Europe. When we turn from the sphere of politics to the history of civilization and culture, we find the effects of the Crusades as deep as if not so definitely marked. The Crusades had sprung from the policy of a theocratic government counting on the motive of otherworldliness; they had helped in their course to overthrow that motive, and with it the government which it had made possible. In part they had provided a field in which the layman could prove that he too was a priest; in part they had brought the West into a living and continuous contact with a new faith and a new civilization. They had torn men loose from the ancestral custom of home to walk in new ways and see new things and hear new thoughts; and some broadening of view, some lessening in the intensity of the old one-sidedness, was the inevitable result. It is not so much that the West came into contact with a particular civilization in the East, or borrowed from that civilization; it is simply that the West came into contact with something unlike itself, yet in many ways as high as, if not higher than, itself. The spirit of Nathan der Weise may not have been exactly the spirit engendered by the Crusades; and yet it is not without reason that Lessing stages the fable which teaches toleration in the Latin kingdom of Jerusalem. In any case the accusations made against the Templars at the time of their suppression prove that there was, at any rate in the ranks of those who knew the East, too little of absolute orthodoxy. While a new spirit which compares and tolerates thus sprang from the Crusades, the large sphere of new knowledge and experience which they gave brought new material at once for scientific thought and poetic imagination. Not only was geography more studied; the Crusades gave a great impulse to the writing of history, and produced, besides innumerable other works, the greatest historical work of the middle ages—the Historia transmarina of William of Tyre. Mathematics received an impulse, largely, it is true, from the Arabs of Spain, but also from the East; Leonardo Fibonacci, the first Christian algebrist, had travelled in Syria and Egypt. The study of Oriental languages began in connection with the Christian missions of the East; Raymond Lull, the indefatigable missionary, induced the council of Vienne to decide on the creation of six schools of Oriental languages in Europe (1311). But the new field of poetic literature afforded by the Crusades is still more striking than this development of science. New poems in abundance dealt with the history of the Crusades, either in a faithful narrative, like that of the Chanson of Amboise, which narrates the Third Crusade, or in a free and poetical spirit, such as breathes in the Chanson d'Antioche. Nor was this all. The Crusades afforded new details which might be inserted into old matters, and a new spirit which might be infused into old subjects; and a crusading complexion thus came to be put upon old tales like those of Arthur and Charlemagne. By the side of these greater things it may seem little, and yet, just because it is little, it is all the more significant that the Crusades should have familiarized Europe with new plants, new fruits, new manufactures, new colours, and new fashions in dress. Sugar and maize; lemons, apricots and melons; cotton, muslin and damask; lilac and purple (azure and gules are words derived
GENEALOGY OF THE KINGS OF JERUSALEM

Godfrey,
advocatus 1099-1100.

Baldwin I.,
brother of Godfrey,
kling 1100-1118.

Baldwin II.,
nephew of Godfrey and Baldwin I.,
and king 1118-1131.

Fulk of Anjou, = Melisinda
king 1131-1143.

Baldwin III.,
king 1143-1162.

Amalric I.,
king 1162-1174.

Alice = Bohemund II.
of Antioch
(¢.7).

Baldwin IV.,
king 1174-1183.

Sibylla = (1) William of Montferrat; (2) Guy de Lusignan,
king 1186-1192.

Baldwin V.,
king 1183-1186.

Isabella = (1) Humphred
of Turon.

Conrad of Montferrat, (3) Henry of Champagne, (4) Amalric II,
acknowledged king
in 1192.

Mary, = John of Brienne,
queen under a regency
from 1205-
1210.

Isabella = Frederick II., emperor
of the West and king
of Jerusalem 1225-
1250.

Conrad IV., king of
Germany and of
Jerusalem 1250-
1255.

Conradin,
king 1254-1268.

Alice = Hugh I. of Cyprus, son
of Amalric II. by his
first wife.

Melisinda = Bohemund IV.

Mary of Antioch, who died 1277,
leaving her claims to Charles
of Anjou (king of Sicily).

Henry I. of Cyprus = Plaisance of Antioch.
Hugh II. of Cyprus.

Isabella = John de Lusignan.

Hugh (III. of Cyprus and)
I. of Jerusalem,
1269-1284.

John I., king of Cyprus,
1284-1285.

Henry (III. of Cyprus and)
II. of Jerusalem, king
from 1285 to the fall of
the kingdom in 1291.
CRUSADES

from the Arabic); the use of powder and of glass mirrors, and also of the rosary itself—all these things came to Europe from the East and have, as a result, had a profound influence. To this day the Crusades are a major part of the vocabulary of the language of western Europe which are a standing witness of the Crusades—words relating to trade and seafaring, like caravans, coffins, or words revealing the use of scientific instruments, like lute or the Elizabethan word "naker."

When all is said, the Crusades remain a wonderful and perpetually astonishing act in the great drama of human life. They touched the summits of daring and devotion, if they also sank into the deep abysses of shame. Motives of self-interest may have lurked in them—otherworldly motives of buying salvation for a little price, or worldly motives of achieving riches and acquiring lands. Yet it would be treason to the majesty of man's incessant struggle towards an ideal good, if one were to deny that in and through the Crusades men strove for righteousness' sake to extend the kingdom of God upon earth. Therefore the tears and the blood that were shed were not unavailing; the heroism and the chivalry were not wasted. Humanity is the richer for the memory of those millions of men, who followed the pillar of cloud and fire in the sure and certain hope of an eternal reward. The ages were not dark in which Christianity could gather itself together in a common cause, and carry the flag of faith and of freedom and of heroism to every corner of the earth. We give thanks for their memory, even if for us religion is of the spirit, and Jerusalem in the heart of every man who believes in Christ.

Literature.—In dealing with the literature of the Crusades, it is perhaps better, though ideally less scientific, to begin with chronicles and narratives rather than with documents. One of the results of the Crusades, as has just been suggested above, was a great increase in the writing of memoirs of the Crusades, and this in the early period was often done under the guise of a "Itineraria"; while home-keeping ecclesiastics in the West—monks like Robert of Reims, abbots like Guibert of Nogent, archbishops like Baldric of Dol—founded a fertile subject for their pens in the history of the Crusades. The history of a series of actions like the Crusades must primarily be based on these accounts, and more particularly on the former; narratives must precede documents where one is dealing, not with the continuous life of an organized kingdom, but with a number of enterprises—especially when those enterprises have been, as in this case, excellently narrated by contemporary writers.

1. Chronicles and Narratives of the Crusades—(1) Collections. The authorities for the history of the Crusades are, in general, the Gesta Francorum (Hanover, 1611) (incomplete); Michel, Bibliothèque des croisades (Paris, 1829) (containing translations of select passages in the authorities); the Recueil des historiens des croisades, published by the Académie des Inscriptions (Paris, 1841 onward) (containing translations of original documents in Latin, Greek, Arabic and Armenian authorities, and also the text of the assizes; but sometimes poorly edited and still incomplete); and the publications of the Société de l'Orient Latin (founded in 1873), especially those of the Revue des croisades, published yearly from 1893 to 1902, and containing not only new texts, but articles and reviews of books which are of great service. (2) Individual authorities. The Crusades—a movement which engaged all Europe and brought the East into contact with the West—must necessarily be studied not only in the Latin authorities of Europe and of Palestine, but also in Byzantine, Armenian and Arabic writers. There are thus some forty or fifty names of importance, which have to be studied.

The First Crusade, far more than any other, became the theme of a multitude of writings, whose different degrees of value is all-important to distinguish. Until about 1840 the authority followed for its history was naturally the Historia Francorum in the事业 of the First Crusade William had followed Albert of Aix; and he had consequently depicted Peter the Hermit as the prime mover in the Crusade. But about 1840 Ranke suggested, and von Sybel in his Geschichte des ersten Kreuzzuges, proved, that Albert of Aix was not a witness of truth, for which purpose the former may be set aside for the history of the First Crusade, and other and more contemporary authorities used. In writing his account of the First Crusade, von Sybel accordingly based himself on the three contemporary ecclesiastics: Anonymus, the Abbot of Nogent, and Fulcher. His view of the value of Albert of Aix, and his account of the First Crusade, have been generally followed (Kugler alone having attempted, to some extent, to rehabilitate Albert of Aix); and thus the work of von Sybel may be said to rest, in the text, in the history of the First Crusade, when its legendary features were stripped away, and its real progress was first properly discovered.

Taking the Western authorities for the First Crusade separately,

one may divide them, in the light of von Sybel's work, into four kinds—the accounts of eye-witnesses; later compilations based on these accounts; semi-legendary and legendary narratives; and lastly, in a class by itself, the "History" of William of Tyre, who is rather a scientific historian than an eyewitness. (a) The three chief eye-witnesses are the anonymous author of the Gesta Francorum, Raymond of Agilus, and Fulcher. The anonymous author of the Gesta (see Hagenmeyer's edition, Heidelberg, 1890) was a Norman of South Italy, who followed Bohemund, and according to the testimony of Peter the Hermit, brought back one of the richest narratives of the First Crusade. He was a layman, marching and fighting in the ranks; and thus he is additionally valuable as representing the opinion of the ordinary crusader. Finally he was an eye-witness throughout, and it is he who recorded the unavailing; and conscientiously written his account of each great event practically at the time of the event. He is the primary authority for the First Crusade. Raymond of Agilus, a Provencal clerk and a follower of Raymond of Toulouse, writes his Historia Raimundi de Agilo (Vienna, 1485), composed between 1194 and 1196, and afterwards followed his fortunes. His Historia Hierosolymitana, which extends to 1127, and embraces not only the history of the First Crusade, but also that of the foundation of the kingdom of Jerusalem, which he describes with truly pre-romantic poetical imagination, is thus a natural complement to the accounts of the Anonymus and Raymond. His account of the First Crusade itself is poor (he was absent at Edessa during its course), but otherwise he is an excellent authority, and perhaps preferable to the other writers, with much discourse on geography, zoology and sacred history. Besides these three chief eye-witnesses we may also mention the Annales Genuenses by the Genoese consul Caffarari,1 and the Annales Pisani by the Provencal ecclesiastic Pierre de Salenstein (see Hagenmeyer's edition, Tübingen, 1877); and the Itinerario of Caen, Gesta Tancredi, composed at about the same time, which contains much interesting information. The last two works, if not actually the works of eye-witnesses, are at any rate first-hand, and belong to the category of primary writers rather than to that of later compilations. Finally, to contemporary writers, we must add contemporary letters, especially those written by Stephen de Blois and Anselm of Ribemont, and the three letters sent to the West by the crusading princes during the First Crusade (see Hagenmeyer, Epistulae et chartae, &c., Innsbruck, 1901).2

2. Compilations. The first编t to an early form of the First Crusade, compiled, according to von Sybel, even during the Crusade itself. The basis of this growth is partly the story-telling instinct innate in all men, which loves to heighten an effect, sharpen a point or convert a very real event of considerable interest into an anecdote, a saga like that of Burnt Njal; partly the instinct of idolization, if it may be so called, which leads to the perversion into impossible greatness of an approved character, and has created, in this instance, the legends of Richard the Lion-hearted, of Bohemund of Taranto, of Hugues, the Abbot of Nogent, or the abbot, the chivalry, the heroism, which were not there at all.

(b) The growth of a legend, or perhaps better, a saga of the First Crusade began, according to von Sybel, even during the Crusade itself. The basis of this growth is partly the story-telling instinct innate in all men, which loves to heighten an effect, sharpen a point or convert a very real event of considerable interest into an anecdote, a saga like that of Burnt Njal; partly the instinct of idolization, if it may be so called, which leads to the perversion into impossible greatness of an approved character, and has created, in this instance, the legends of Richard the Lion-hearted, of Bohemund of Taranto, of Hugues, the Abbot of Nogent, or the abbot, the chivalry, the heroism, which were not there at all.

(c) The growth of a legend, or perhaps better, a saga of the First Crusade began, according to von Sybel, even during the Crusade itself. The basis of this growth is partly the story-telling instinct innate in all men, which loves to heighten an effect, sharpen a point or convert a very real event of considerable interest into an anecdote, a saga like that of Burnt Njal; partly the instinct of idolization, if it may be so called, which leads to the perversion into impossible greatness of an approved character, and has created, in this instance, the legends of Richard the Lion-hearted, of Bohemund of Taranto, of Hugues, the Abbot of Nogent, or the abbot, the chivalry, the heroism, which were not there at all.

1. His somewhat legendary treatise, De liberatione civitatum Orientis, was only composed about 1155.

2. There is also an Inventaire critique of these letters by the comte de Riant (Paris, 1880).
inconsistencies, its errors of chronology and topography, its poetical colour, and its living descriptions of battles. Kugler, however, regards Albert as a copyp, somewhat in the manner of Tudebod, of an unknown writer of value, who belonged to the Lotharingian rank and file, and to the kingdom of Jerusalem, and his works are praised as having been derived from the latter. This is a poem written about 1180 by Grinoard de Douai, who used as his basis the verses of the crusader Richard (see the edition of P. Paris, 1848). It shows the growth of the legend that Grinard regarded the Hermit as responsible for the Crusades, and makes the Crusades by Richard a by-way to the earlier failure, the meeting at Clermont (which is dated in May instead of November). Into the legendary overgrowth of the First Crusade we cannot here enter any further; but it is perhaps worth while to mention that its reception at Saracen length was such as to pervert the truth, making Richard I. return home in disgrace, while Philip Augustus stays, captures Damasucus and mortally wounds Saladin (cf. G. Paris, L'Estoire de la guerre sainte, Paris, 1839, Introduction).

(d) William of Tyre is the scientific historian and rationalizer, weaving into a harmonious account, which was followed by historians for centuries, the sober accounts of eye-witnesses and the picturesque tales of monks, with somewhat of a bias towards the former in the regard to the First Crusade. He was a native of Palestine, born about 1130, and educated in the West. On his return he was given in winning the good opinion of Amalric I.; he was made first secretary and second in the reigns of the last three kings of Jerusalem: Baldwin IV. (1170); while on Baldwin's accession he became chancellor of the kingdom and archbishop of Tyre (1174-1175). He was a man often employed on missions and negotiations, and as chancellor he had in his hand the archives of the kingdom. His temper was mild, he had the qualifications for the writing of well-informed and unbiased history. He knew Greek and Arabic; and he was well acquainted with the affairs of Constantinople, to which he went at least twice on political business. But it is in his history that his merit is specially manifested. He had written a work (now lost) at the command of Amalric. It was Amalric also who set him to write the history of the Crusades which we still possess (in twenty-two books, with a fragment of a twenty-third, of the original) which it is claimed by many contemporary writers, who wrote the book at different times between 1170 and 1183, when it abruptly ends, and its author as abruptly disappears from sight. The book falls into two parts, the first (books i.-xv.) derivative, the second part (books xvi.-xxi.) original. In the second part he has his own knowledge of events and the information of his contemporaries as his source: in the first he used the same authorities which we still possess—the Gesta, Fulcher, and Albert of Aix—in somewhat of an emendatory spirit, but he could best weave a pleasant narrative, but not according to any critical principle. His book thus begins to be a real authority only from the date of the Second Crusade onwards; but the perfection of his narrative is, perhaps, in the last books, written after the death of the king, and the prestige of his position conspired to make his book the true authority for the whole history of the first century of the Crusades. He was, however, apart from his reception of legendary elements into his narrative, the most valuable of the historians of the Crusades, for the unity of the honour in which he was held; for he is a real great historian, in the form of his matter and in his conception of his subject—diligent, impartial, well-informed and interesting, if somewhat rhetorical in style and vague in chronology. (During the middle ages his work was current in a French translation, known as the Chronique d'outremer, or the Lire ou Roman d'Éracles (so called from the reference at the beginning to the emperor Heraclius). This translation also contained a continuation by various hands down to 1277; while besides the continuation embodied in the Lire d'Éracles, there are separate continuations, of the Gesta, of the Life of the Holy Cross, of the History of Roger of Howden and Bouiccau, etc. These latter cover the period from 1183 to 1228; and of the two Ernoul accounts seems primary, while that of Bernard is in large part a mere copy of Ernoul. But the whole subject of the continuation by various hands down to 1277 is为广大 unpopular.)

To the Western authorities for the First Crusade must be added the Eastern—Byzantine, Arabic and Armenian. Of these the Byzantine authority, the Alexiad of Anna Comnena, is most important, for it contains, besides his own account, the letters of the emperors and the relations of the crusaders, and many points of contact between the Byzantine empire and the Crusades. Anna's narrative both furnishes a useful correlative of

1 Von Sybel's view must be modified by that of Kugler, who is a scholar like Hagenmeyer has to some extent gained his approval (in his edition of the Gesta, pp. 62-68). Hagenmeyer inclines to believe in an original author, distinct from Albert the copyp; and he thinks that this original author (whether or no he was present during the Crusade) used the Gesta and also Fulcher, though he had probably also "eigen Notizen und Aufzeichnungen."

2 See Pigonette, Le Cycle de la croisade, &c. (Paris, 1877), and Hagenmeyer, Peter der Eremite (Leipzig, 1879).

The Armenian view of the First Crusade and of Baldwin's principality of Edessa is presented in the Armenian Chronicle of Matthew of Edessa. There is little in Arabic bearing on the First Crusade; the Arabic authorities only begin to be of value with the rise of the imam al-Mustansir (c. 1177). But Keralal-ud-din's History of Aleppo (composed in the 13th century) contains some details on the history of the First Crusade, and that of the Ommiades (the autobiography of a sheik at Caesarea in northern Syria, edited in the 14th century and published in the Publications de l'École des langues orientales vivantes) presents the point of view of an Arab whose life covered the first century of the Crusades (1065-1187).

For the second crusade the primary authority in the West is the work of Odo de Deul, De professione Ludovici VII regis Francorum in Oriente. Odo was a monk attached to Suger to Louis VII during the Second Crusade; and he wrote home to Suger during the course of the Crusade. His matter also comes together in a single work. The Gesta Frederici Primi of Otto de Freising (who joined in the Second Crusade) gives some details from the German point of view (l. c. 44 sqq.). The former is supplemented by the letters of Louis VII to Suger; the latter by the chart, 1866, Conrad III. to Wibald, abbots of Stablo and Corvey. The Byzantine point of view is presented in the Ermouph of Cinnamus, the private secretary of Manuel, who continued the Alexiad of Anna Comnena in a work described as the continuation of the Second Crusade that William of Tyre, representing the attitude of the Franks of Jerusalem, begins to be a primary authority; while on the Mahomedan side a considerable authority emerges in Ibn Athir. Generally speaking the Arabic writings are late in point of date, and cold and jejune in style; while it must also be remembered that they were written in the light of the age of which they are the products. On the other hand they are generally written by men of affairs—governors, secretaries or ambassadors; and a fatalistic temper leads their authors to a certain impartial recording of everything, good or evil, without polemic or patriotic considerations. The Third Crusade was narrated in the West from very different points of view by Anglo-Norman, French and German authorities. The primary Anglo-Norman authority is the Carmen Ambrosii, or, as it is also called, the Historia Curiosorum. It is an octosyllabic poem in French verse, written by Ambroise, a Norman trouvere who followed Richard I. to the Holy Land. The poem first came to be known by scholars about 1873, and has been edited in the Storia dei Tempi (1882) and by M. de M. T. The French poets' and the Middle English versions of the Carmen of the Crusades are, for the most part, translations of the Carmen, masquerading under the guise of an independent work. There seems no doubt that it is a piece of plagiaric, or, rather, plagiary, work. It is translated in the Caram of the Third Crusade, and there stands to the Carmen as Tudobod to the Gesta of Aix to his supposed original. The Third Crusade is also described from the English point of view by all contemporary writers of history in England, e.g. Ralph of Coggeshall, who used information gained from crusaders, and William of Newburgh, who had access to a work by Richard I.'s chaplain Anselm, which is now lost. The French side is presented in Rigord's Gesta Philippii Augusti and in the Gesta (an abridgment and continuation of Rigord) and the works of the English writers, and of William the Breton. The two French writers represent Richard as a faithless vassal: in the German writers—Tagino, dean of Passau, who wrote a Descriptio of Barbarossa's Crusade (1199-1198); and Ansbert, an Austrian clerk, who wrote De expugnatione. In the German writers Richard is represented as a monster of pride and arrogance. From the Arabic point of view the life of Richard's rival, Saladin, is described by Beha-ud-din, a high official under Saladin, who writes a panegyric on his master, somewhat in chivalric manner, but who were not nevertheless of great value. The various continuations of William of Tyre above mentioned represent the opinion of the native Franks (which is hostile to Richard I.); while in Nicetas, who wrote a history of constantine's reign, some clausal comparison of the Byzantine authority who, as Professor Bury remarks, "differs from Anna and Cinnamus in his tone towards the crusaders, to whom he is surprisingly fair." For the Fourth Crusade the primary authority is Villehardouin's La Conquete de Constantinople, an official apology for the diversion of the Crusade written by one of its leaders, and concealing the arcana under an appearance of frank naiveté. Its work is usefully supplemented by the narrative (La Prise de Constantinople) of

1 On the bibliography of the Second Crusade see Kugler, Studien zur Geschichte des zweiten Kreuzzuges (Stuttgart, 1866).

2 Of these writers see Archer's Crusade of Richard I., Appendix (In Nutt's series of Histories from Contemporary Writers).
CRUSENSTOLPE-CRUSTACEA

Robert de Clary, a knight from Picardy, who presents the non-
official view of the Crusade, as it appeared to an ordinary soldier. The
 크로스네스 tollpe
(contains in Greek verse some time after 1300, apparently by an author of mixed Frankish and Greek
background, and translated into Latin at an early date under the
title “The Book of the Conquest of Constantinople and the Empire of
 Romania”) narrates in a prologue the events of the Fourth (as
indeed also of the First) Crusade. The Chronicle of the Morea (as
this work is generally called) is written from the Frankish point of
view of the Crusades, mostly of Greek verse; and the Byzantine point of
view must be sought in Niceas.1

The history of the later Crusades, from the Fifth to the Eighth,
enters into the continuations of William of Tyre above mentioned;
while the chronicles of St. Louis, Fulcher of Chartres, and the
history of the Crusade, written by a master of French versification,
the latter especially for the Crusade of Frederick II. The minor authorities for
the Fifth Crusade have been collected by Röhrich, in the publications
of the Société de l’ Orient Latin for 1879 and 1882; the ten valuable
letters of Oliver, bishop of Paderborn, in the Historia Germanica,
based on these letters, have also been edited by Röhrich in the
Westdeutsche Zeitschrift für Geschichte und Kunst (1891). The Sixth
Crusade, that of Frederick II., is described in the chronicle of
Richard of San Germano, a notary of the emperor, and in other
Western authorities, e.g. Roger of Wendover. For the Crusades of
St. Louis the chief authorities are Joinville’s life of his master (whom
he accompanied to Egypt on the Seventh Crusade), and de Nangis’
Gesta Ludovici regis Francorum qui in Oriente in temporibus
Friderici regis (Nuremberg, 1832).

The text of the Regesta regni Hierosolymitani, published by
Under the law of the Levant, this is given in Le Liber des lignages d’outre-mer (published along with
the above).

1 The bibliography of the Fourth Crusade is discussed in Klimek,
Die Quellen zur Geschichte des vierten Kreuzzugs (Breslau, 1875).

252

CRUSENSTOLPE, MAGNUS JAKOB (1795-1865). Swedish
historian, early became famous both as a political and a
historical writer. His first important work was a History of
the Early Years of the Life of King Gustavus IV. Adolphus,
which was followed by a series of monographs and some
polti-co-historical novels, of which The House of Holstein-Gottorp
in Sweden is considered the best. He obtained a great influence
over King Charles XIV. (Bernadotte), who during the years 1830-
1833 gave him his fullest confidence, and sanctioned the official
character of Crusenstolpe’s newspaper Fädersamelsetd. In
the last-mentioned year, however, the historian suddenly
became the king’s bitter enemy, and used his acid pen on
occasions in attacking him. In 1838 he was condemned, for
one of these articles, to be imprisoned three years in the
castle of Waxholm. He continued his newspaper work until
1865. Few Swedish writers have wielded so pure and so
incisive a style as Crusenstolpe, but his historical work is vitiated
by political and personal bias.

CRUSIUS, CHRISTIAN AUGUST (1715-1755). German philo-
osopher and theologian, was born on the 16th of January 1715
at Lennau near Merseburg in Saxony. He was educated at
Leipzig, and became professor of theology there in 1750,
and principal of the university in 1773. He died on the 18th of
October 1775. Crusius first came into notice as an opponent
of the philosophy of Leibniz and Wolff from the standpoint
of religious orthodoxy. He attacked it mainly on the score
of the moral evils that must flow from any system of
determinism, and exerted himself in particular to vindicate the
freedom of the will. The most important works of this period of
his life are Entwurf der nothwendigen Vernunftwahrheiten (1745),
and Weg zur Gewissheit und Zuverlässigkeit der menschlichen
Erkennniss (1747). Though diffusely written, and neverthet
nevertheless, Crusius’ philosophical books had a great but short-
lived popularity, as did Wolff’s, which is generally based
on sound sense, but had much influence because of the
same time when his system was forming; and his ethical
doctrines are mentioned with respect in the Krüth of Practical
Reason. Crusius’s later life was devoted to theology. In this capacity his
serene piety and amiable character gained him great influence,
and he led the party in the university which became known as the
“Crusianer” as opposed to the “Erneust Party,” the followers of
J. A. Ernesti. The two professors adopted opposite methods
of exegesis. Ernesti wished to subject the Scripture to the
same laws of exposition as are applied to other ancient books;
Crusius held firmly to orthodox ecclesiastical tradition.
Crusius’s chief theological works are Hypommene ad theologiam
præthecittam (1764-1778), and Kurzer Entwurf der Moraltheologie
(1777-1773). He sets his face against innovation in such matters
as the accepted authorship of canonical writings, verbal inspec-
tion, and the treatment of persons and events in the Old
Testament as types of the New. His views, unscholarly and
sectarian as they seem to us now, had influence on later
traditional and biblical exegesis in the Old Testament, such as E. W.
Herzog-Hauck, and F. Delitzsch.

There is a full notice of Crusius in Ersch and Gruber’s Allgemeine
Encyclopädie. Consult also J. E. Erdmann’s History of Philosophy;
A. Marquard, Kant und Crusius; and art. in Herzog-Hauck,
Redenzikon (1898).

CRUSTACEA, a very large division of the animal kingdom,
comprising the familiar crabs, lobsters, crayfish, shrimps and
prawns, the sandhoppers and woodlice, the strangely modified
barnacles and the minute water-fleas. Besides these the group
also includes a multitude of related forms which, from their

social history of the Latin kingdom of Jerusalem Dudo’s Histoire des institutions
du royaume latin de Jerusalem is very useful; E. G. Rey’s
Les Colonnes franques en Syrie contains many interesting
details; and Prutz’s Kulturgeschichter der Kreuzzüge contains both an
account of the Latin East and an attempt to sketch the effects of the Crusades
on the progress of civilization. The works of Gmelin and J. Dela-
valie-Leroux on the Templars and Hospitaliters respectively are
worth consulting; while for Eastern affairs the English reader
may be referred to G. Lessing’s Palestine unter den Muselm, and to
Stanley Lane-Poole’s Life of Saladin and his Muhammadan Dynasties
the latter a valuable work of reference.

(E. Br.)
aquatic habits and generally inconspicuous size, and from the fact that they are commonly neither edible nor noxious, are little known except to naturalists and are undistinguished by any popular names. Collectively, they are ranked as one of the classes forming the sub-phylum Arthropoda, and their distinguishing characters are discussed under that heading. It will be sufficient here to define them as Arthropoda for the most part of aquatic habits, having typically two pairs of antenniform appendages in front of the mouth and at least three pairs of post-oral limbs acting as jaws.

As a matter of fact, however, the range of structural variation within the group is so wide, and the modifications due to parasitism and other causes are so profound, that it is almost impossible to frame a definition which shall be applicable to all the members of the class. In certain parasites, for instance, the adults have lost every trace not only of Crustacean but even of Arthropodous structure, and the only clue to their zoological position is that afforded by the study of their development. In point of size also the Crustacea vary within very wide limits. Certain water-fleas (Cladocera) fall short of one-hundredth of an inch in total length, while the giant Japanese crab (Macrocheira) can span over 15 ft. between its outstretched claws.

The habits of the Crustacea are no less diversified than their structure. Most of them inhabit the sea, but representatives of all the chief groups are found in fresh water (though the Cirripedia have hardly gained a footing there), and this is the chief home of the primitive Phyllopoda. A terrestrial habitat is less common, but the widely-distributed land Isopoda or woodlice and the land-crabs of tropical regions have solved the problem of adaptation to a subaerial life.

Swimming is perhaps the commonest mode of locomotion, but numerous forms have taken to creeping or walking, and the robber-crab (Birgus latro) of the Indo-Pacific islands even climbs palm-trees. None has the power of flight, though certain pelagic Copepoda are said to leap from the surface of the sea like flying-fish. Apart from the numerous parasitic forms, the only Crustacea which have adopted a strictly sedentary habit of life are the Cirripedia, and here, as elsewhere, profound modifications of structure have resulted, leading ultimately to a partial assumption of the radial type of symmetry which is so often associated with a sedentary life.

Many, perhaps the majority, of the Crustacea are omnivorous or carrion-feeders, but many are actively predatory in their habits, and are provided with more or less complex and efficient instruments for capturing their prey, and there are also many plant-eaters. Besides the sedentary Cirripedia, numbers of the smaller forms, especially among the Entomostraca, subsist on floating particles of organic matter swept within reach of the jaws by the movements of the other limbs.

Symbiotic association with other animals, in varying degrees of interdependence, is frequent. Sometimes the one partner affords the other merely a convenient means of transport, as in the case of the barnacles which grow on, or of the gulf-weed crab which clings to, the carapace of marine turtles. From this we may pass through various grades of "commensalism," like that of the hermit-crab with its protective anemones, to the cases of actual parasitism. The parasitic habit is most common among the Copepoda and Isopoda, where it leads to complex modifications of structure and life-history. Perhaps the most complete degeneration is found in the Rhizocephala, which are parasitic on other Crustacea. In these the adult consists of a simple sacculary body containing the reproductive organs and attached by root-like filaments which ramify throughout the body of the host and serve for the absorption of nourishment (fig. 1).

Many of the larger species of Crustacea are used as food by man, the most valuable being the lobster, which is caught in large quantities on both sides of the North Atlantic. Perhaps the most important of all Crustacea, however, with respect to the part which they play in the economy of nature, are the minute pelagic Copepoda, of which in calculable myriads form an important constituent of the "plankton" in all the seas of the globe. It is on the plankton that a great part of the higher animal life of the sea ultimately depends for food. The Copepoda live upon the diatoms and other important microscopic vegetable life at the surface of the sea, and in their turn serve as food for fishes and other larger forms and thus, indirectly, for man himself.

Historical Sketch.—In common with most branches of natural history, the science of Carcinology may be traced back to its beginnings in the writings of Aristotle. It received additions of varying importance at the hands of medieval and later naturalists, and first began to assume systematic form under the influence of Linnaeus. The application of the morphological method to the Crustacea may perhaps be dated from the work of J. C. Fabricius towards the end of the 17th century.

In the first quarter of the 19th century important advances in classification were made by P. A. Latreille, W. E. Leach and others, and J. Vaughan Thompson demonstrated the existence of metamorphosis in the development of the higher Crustacea. A new epoch may be said to begin with H. Milne-Edwards' classical Histoire naturelle des crustacés (1834–1840). It is noteworthy that even at this late date the Cirripedia (Thyrostraca) were still excluded from the Crustacea, though Darwin's Monograph (1851–1854) was soon to make them known with a wealth of anatomical and systematic detail such as was available, at that time, for few other groups of Crustacea.

About the same period there is a special mention, W. de Haan, J. D. Dana and H. Kröyer. The new impulse given to biological research by the publication of the Origin of Species brought in Fritz Müller's Für Darwin, in which an attempt was made to reconstruct the phylogenetic history of the class. The same line of work was followed in the long series of important memoirs from the pen of K. F. W. Claus, and noteworthy contributions were made, among many others, by A. Dohrn, Ray Lankester and Huxley. In more recent years the long and constantly increasing list of writers on Crustacea contains no name more honoured than that of the veteran G. O. Sars of Christiania.

Morphology. External Structure: Body.—As in all Arthropoda the body consists of a series of segments or somites which may be free or more or less coalesced together. In its simplest form the exoskeleton of a typical somite is a ring of chitin defined from the rings in front and behind by areas of thinner integument forming moveable joints, and having a pair of appendages articulated to its ventral surface on either side of the middle line. Frequently, however, this exoskeletal somite may be differentiated into various regions. A dorsal and a ventral plate are often distinguished, known respectively as the tergum and the sternum, and the tergum may overhang the insertion of the limb on each side as a free plate called the pleuron. The name epimeron is sometimes applied to what is here called the pleuron, but the word has been used in widely different senses.

The typical form of a somite is well seen, for example, in the segments which make up the abdomen or tail of a lobster or crayfish (fig. 2). The posterior terminal segment of the body, on which the opening of the anus is situated, never bears appendages. The nature of this segment, which is
known as the "anal segment" or telson (fig. 3, T), has been much discussed, some authorities holding that it is a true somite, homologous with those which precede it. Others have regarded it as representing the fusion of a number of somites, and others again as a "median appendage" or as a pair of appendages fused. Its morphological nature, however, is clearly shown by its development. In the larval development of the more primitive Crustacea, the number of somites, at first small, increases by the successive appearance of new somites between the last-formed somite and the terminal region which bears the anus. The "growing point" of the trunk is, in fact, situated in front of this region, and, when the full number of somites has been reached, the unsegmented part remaining forms the telson of the adult.

In no Crustacean, however, do all the somites of the body remain distinct. Coalescence, or suppression of segmentation ("limomerism"), may involve more or less extensive regions. This is especially the case in the anterior part of the body, where, in correlation with the "adaptational shifting of the oral aperture" (see Arthropoda), a varying number of somites unite to form the "cephalon" or head. Apart from the possible existence of an ocular structure and development which seem to place them in a different category from the other limbs, and there is some ground for regarding the three corresponding somites as constituting a "primary cephalon." For practical purposes, however, it is convenient to include the two following somites also as cephalic.

A remarkable feature found only in the Stomatopoda is the reappearance of segmentation in the anterior part of the cephalic region. Whether the movably articulated segments which bear the eyes and antennules arise from the primitively fused cephalic segments or not, there is no certain evidence of their having been derived from the same or any other "thetic" segments. Whether the cervical segments or the secondarily acquired cephalic segments are derived from the thorax or not, there is no certain evidence of their having been derived from the same or any other "thetic" segments. Whether the cervical segments or the secondarily acquired cephalic segments are derived from the thorax or not, there is no certain evidence of their having been derived from the same or any other "thetic" segments.

Fig. 3.—The Separated Somites and Appendages of the Common Lobster (Homarus gammarus).

C, carapace covering the cephalothorax.
Ab, abdominal somites.
T, telson, having the uropods or appendages of the last abdominal somite spread out on either side of it, forming the "tail-fan."
I, labrum, or upper lip.
m, metastoma, or lower lip.
1, eyes.
2, antennule (the arrow points to the opening of the so-called auditory organ).
3, antenna.
4, mandible.
5, maxillula (or first maxilla).
6, maxilla (second maxilla).
7-9, first, second and third maxillipeds.
ex, exopodite.
ep, epipodite.
g, gill.
10, sixth thoracic limb (second walking-leg) of female.
11, last thoracic limb of male.
In 10 and 11 the arrows indicate the genital apertures.
12, third abdominal somite, with appendages or "swimmerets."
13, sterna of the thoracic somites, from within.
14, external Ideas, showing of the so-called cephalic appendages.

somite corresponding to the eyes (the morphological nature of which is discussed below), the smallest number of head-somites so united in any Crustacean is five. Even where a large number of the somites have fused, there is generally a marked change in the character of the appendages after the fifth pair, and since the integumental fold which forms the carapace seems to originate from this point, it is usual to take the fifth somite as the morphological limit of the cephalon throughout the class. It is quite probable, however, that in the primitive ancestors of existing Crustacea a still smaller number of somites formed the head. The three pairs of appendages present in the "nauplius" larva show certain peculiarities of...
Phyllopoda (fig. 6) and in the Ostracoda. In the Cirripedia it forms a fleshy "mantle" strengthened by shelly plates or valves which may assume a very complex structure. In many cases, however, the shell-fold coalesces with some of the succeeding somites. In the Decapoda (fig. 3), this coalescence affects only the dorsal region of the thoracic somites, and the lateral portions of the endopodite overhang on each side, enclosing a pair of chambers within which lie the gills. The arrangement is similar in Schizopoda and Stomatopoda (fig. 7), except that the coalescence does not usually involve the posterior thoracic somites, several of which remain free, though they may be overlapped by the carapace.

In the Isopoda and Amphipoda, where, as a rule, all the thoracic somites except the first are distinct (fig. 4), there seems at first sight to be no shell-fold. A comparison with the related Tanaidacea (fig. 5) and Cumacea (or Synopoda), however, leads to the conclusion that the coalescence of the first thoracic somite with the cephalon really involves a vestigial shell-fold, and, indeed, traces of this are said to be observed in the embryonic development of some Isopoda. It seems likely that a similar explanation is to be applied to the coalescence of one or two trunk-somites with the head in the Copepoda, and, if this be so, the only Crustacea remaining in which no trace of a shell-fold is found in the adult are the Anostracous Phyllopoda such as Branchipus (fig. 5).

General Morphology of Appendages.—Among the variety of forms assumed by the appendages of the Crustacea, it is possible to trace, more or less plainly, the modifications of a fundamental type consisting of a peduncle, the protopodite, bearing two branches, the endopodite, and exopodite. This simple biramous form is found in the swimming-feet of the Copepoda and Branchiura, the "cirri" of the Cirripedia, and the abdominal appendages of the Malacostraca (fig. 5, 14). It is also found in the earliest and most primitive form of larva, known as the Nauplius. As a rule the protopodite is in the form of a pair of segments, though one may be reduced or suppressed and occasionally three may be present. In many cases, one of the branches, generally the endopodite, is modified in a different way from the other. Thus, in the thoracic limbs of the Malacostraca, the endopodite generally forms a walking-leg while the exopodite becomes a swimming-branch or may disappear altogether. Very often the basal segment of the protopodite bears, on the outer side, a branchial appendage (fig. 7, two), the epipodite, which may function as a gill. In the appendages near the mouth one or both of the protopodial segments may bear inwardly-turned processes, assisting in mastication and known as gnathobases. The frequent occurrence of epipodites and gnathobases tends to show that the primitive type of appendage was more complex than the simple biramous limb, and some authorities have regarded the leaf-like appendages of the Phyllopoda as nearer the original form from which the various modifications in other groups have been derived. In a Phyllopod such as Aplus the limbs of the trunk consist of a flattened, unsegmented or obscurely segmented axis or corn having a series of lobes or processes known as endites and exites on its inner and outer margins respectively. In all the Phyllopoda the number of endites is six, and the proximal one is more or less distinctly specialized as a gnathobase, working against its fellow of the opposite side in seizing food and transferring it to the mouth. The Phyllopoda are the only Crustacea in which distinct and functional gnathobasic processes are found on appendages far removed from the mouth. The two distal endites are regarded as corresponding to the endopodite and exopodite of the higher Crustacea, the axis or corn of the Phyllopod limb representing the protopodite. The number of exites is less constant, but, in Aplus, two are present, the proximal branchial in function and the distal forming a stiffer plate which probably aids in swimming. It is not altogether easy to recognize the homologies of the endites and exites even within the order Phyllopoda, and the identification of the two distal endites as corresponding to the endopodite and exopodite of the higher Crustacea is not free from difficulty. However, that the biramous limb is a simplification of a more complex primitive type, to which the Phyllopod limb is a more or less close approximation.

The modifications which this original type undergoes are usually more or less plainly correlated with the functions which the appendages have to discharge. Thus, when acting as swimming organs, the appendages, or their rami, are more or less flattened, or oar-like, and cannot be said that this point has been fully settled. The jaw with the gnathobasic endites developed at the expense of the rest of the limb, the endopodite and exopodite persisting only as sensory "palps" or disappearing altogether. When specialized as bearers of sensory (olfactory or tactile) organs, the rami are generally elongated, many-jointed and filiform, and in these cases the endopodite and exopodite may be reduced or suppressed, or suppressed altogether. This modification is usually only found in the appendages of the trunk, as, for instance, in the thoracic legs of some Decapods (e.g., Mastingheirius). Very often one or other of the appendages may be modified for prehension, the seizing of prey or the holding of a mate. In this case, the claw-like terminal segment may be simply flexed against the preceding in the same way as the blade of a penknife shuts up against the handle. The penultimate segment is often broadened, so that the terminal claw shuts against a transverse edge (fig. 4), or, finally, the penultimate segment may be produced into a thumb-like process opposed to the movable terminal segment or finger, forming a perfect chela or forceps, as, for instance, in the large claws of a crab or lobster. This chelate condition may be assumed by almost any of the appendages, and sometimes it cannot be said that this point has been fully settled. The evidence of embryology is decidedly against the view that the eye-stalks are limbs. They are absent in the earliest and most primitive
larval forms (nauplii), and appear only late in the course of development, after many of the trunk-limbs are fully formed. In the development of the Phyllopod Branchipus, the eyes are at first sessile, and the lateral lobes of the head on which they are set grow and become more articulated, forming the peduncles. The most important evidence in favour of their appendicular nature is afforded by the phenomena of regeneration. When the eye-stalks are removed from a living lobster or prawn, it is found that under certain conditions a many-jointed appendage like the flagellum of an antennule is formed. It is, however, possible to doubt, however far the evidence from such "hematogenous regeneration" can be regarded as conclusive on the points of homology. The fact that in certain rare cases among insects a leg may appear apparently in the wrong place, and may be termed "paragnatha," in the fact that they are always innervated from the "brain" (or preoral ganglia), and that they are uniramous in the nauplius larva and in all the Entomostraca orders. As regards their innervation an apparent exception is found in the case of A. pus, where it seems to the antennules arise, behind the brain, from the oesophageal commissures, but this is, no doubt, a secondary condition, and the nerve-fibres have been traced forwards to centres within the brain. In the Cladocera, the antennules are often biramous, but there is considerable doubt as to whether the two branches represent the endopodite and exopodite of the other limbs, and three branches are found in the Stomatopoda and in some Caridea. In the great majority of Crustacea the antennules are purely sensory in function and are developed from the sensory processes of the antennae, not nattorally as in many Ostracoda and Copepoda, or prehensile, as in some Copepoda. The most peculiar modification, perhaps, is that found in the Cirripedia (Thyrostraca), in the larvae of which the antennules are modified in an interesting way, to form a spiracle, but to the attachment of the animal to its support. The antennae (second antennae) are of special interest on account of the development of the proboscis. In the Crustaceans, they were originally postoral appendages. In the nauplius larva they lie rather at the sides than in front of the mouth, and their basal portion carries a hook-like masticatory process which assists in the work of disengagement. In the larval stages of the primitive Phyllopoda, and less distinctly in some other orders, the nerves supplying the antennae arise, not from the brain, but from the circum-oesophageal commissures, and even in those cases where the nauplius larva is provided with appendages these do not become modified out of the antennules. In some cases, it is believed, the antenneles forwards to the brain, the transverse commissure of the ganglia can still be traced, running behind the oesophagus. The functions of the antennae are more varied than is the case with the antennules. In many Entomostraca (Phyllopoda, Clado- cera, etc.), the antennae serve as organs of locomotion, while in some male Phyllopoda they form complex "claspers" for holding the female. They are frequently organs of attack in parasitic Copepoda, and they may be completely detached from the body-wall in some cases. In the Ostracoda they are often used as "baskets" in the mouth, and in the Cladocera, the antennules are sometimes lost as the animals mature, and the antennae, especially in the larvae, continue to serve as organs of locomotion. The mandibles, like the antennae, may be found in the nauplius, the form of biramous swimming limbs, with a masticatory process originating from the proximal part of the exopodite. This form is frequently found with little alteration in some adult Copepoda, where the biramous "palp" still aids in locomotion. A somewhat similar structure is found also in some Ostracoda. In most cases, however, the palp loses its masticatory power, and the slender swimming segment forms the body of the mandible, with a masticatory edge variously armed with teeth and spines. In a few Ostracoda, by a rare exception, the masticatory process is reduced or suppressed, and the palp alone remains, forming a podiform appendage used in locomotion only, with a single endopodite and an exopodite bearing the secondarily modified forms of the masticatory apparatus. The palp and the mandible are enclosed in a tubular process formed by the union of the upper lip (labrum) with the lower lip (hypostome or paragynophore). The maxillipedae and maxillae (or, as they are often termed, first and second maxillae) are nearly always flattened leaf-like appendages, having gnathoblastic lobes or endites borne by the segments of the protopodite. The endopodite, which is present, is usually composed of several segments and forms the "palp," and outwardlydirected lobes representing the exopodite and epipodites may also be present. These limbs undergo great modification in the different groups, and are variously modified as maxillipeds or as "paragnatha," or lobes of the lower lip, when these are present, and it has been suggested that the paragnatha are really the basal endites which have become partly separated from the rest of the appendage. The limbs of the postcephalic series show little differentiation among themselves in many Entomostraca. In the Phyllopoda they are for the most part all alike, though one or two of the anterior pairs may be specialized as sensory (A. pus) or grasping (Euphausiacea) organs. In the Cirripedia (Thyrostraca) the six pairs of biramous cirriform limbs differ only slightly from each other, and in a nauplius larva Copepoda this is also the case. In other Entomostraca considerable differentiation may take place, but the series is never divided into definite "ragnosta" or groups of similarly modified appendages. It is highly characteristic of the Malacostraca, however, that the trunk limbs are divided into two groups, the former corresponding to the thoracic and abdominal regions respectively, the limit between the two being marked by the position of the male genital openings. The thoracic limbs have the endopodites converted, as a rule, to the service of the mouth, forming "foot-jaws" or maxillipeds. In the Decapoda three pairs are thus modified, and in the Tanaidacea, Isopoda and Amphipoda only one. In the Chaetognatha and Cumacea the head by a division is less sharp, and the varying number of so-called mandibles and maxillules, and the presence or suppression of appendages rise to some confusion of terminology in systematic literature. **Gills.**—In many of the smaller Entomostraca (Copepoda and most Ostracoda) no special gills are present, and respiration is carried on by the branchial appendages, which are often gills process, the branchial appendages are generally differentiated as parts of the appendages, most often the epipodites, as in the Phyllopoda. In the Cirripedia, however, they are vascular processes from the inner surface of the mouth, and in the Copepoda, they are outgrowths from the sides of the body. In the primitive Malacostraca the gills were probably, as in the Phyllopoda and in Nebalia, the modified epipodites of the thoracic limbs, and this is the condition found in some cases in some of the Tanaidacea. In Thoracostraca the thoracic limb has a branchial epipodite. In the Amphipoda, the gills though arising from the inner side of the branchial appendages are probably also epipodital in nature. In the Isopoda the first pair of appendages is modified into true gills, but the appendages, both rami or only the inner becoming thin or flattened. In the Decapoda the branchial system is more complex. The gills are inserted at the base of the thoracic limbs, and lie within a pair of branchial chambers covered by the carapace. Three series of gills are given off, the first pair is the hypandrium, giving off the appendages, pterobranchia, spiriting from the body-wall, and an intermediate series, arthrobranchia, inserted on the lateral membrane of the membrane between the branchial appendages. In the Podo-branchia the gills are united to form a sac or gill chamber, and in the Branchiopoda and Cephalostraca they are modified into epipodites, and it is probable that the arthro- and pleuro-branchia are also epipodital in origin and have migrated from the proximal segment of the limbs on to the adjacent body-wall. The gills of some species of some of the landcrabs, where the lining membrane of the gill-chamber is beset with vascular papillae and acts as a lung. In some of the terrestrial Isopoda or woodlice (Oniscoida) the abdominal appendages have been much modified by the invaginations of the integument, filled with air and resembling the tracheae of insects. **Internal Structure: Alimentary System.—**In almost all Crustacea the food-canal runs straight through the body, except at its anterior end, where it is coiled, or forms a coiled "palp," or "hindgut". In a few cases its course is slightly sinuous or twisted, but the only cases in which it is actually coiled upon itself are found in the Cladocera of the family Lymneidae (Lymneidae) and in a single recently-discovered genus of Cumacea (Symphyla). As in all Arthropods, the alimentary tract is divided into a fore-gut, mid-gut and hind-gut, each of these divisions vary considerably, and the extreme abbreviation of the mid-gut found in the common crayfish (Astacus) is by no means typical of the class. Even in the closely-related lobster (Homarus) the mid-gut is well developed. In a few Entomostraca (some Phyllopoda and Ostracoda) the chitinous lining of the fore-gut develops spines and hairs which help to triturate and strain the food, and among the Ostracoda there is an occasional (Bastida) an especially elaborated arrangement of these plates is moved by muscles. It is among the Malacostraca, however, and especially in the Decapoda, that the "gastric mill" reaches its greatest perfection. In most Decapods the "stomach" or dilated portion of the fore-gut is divided into two chambers, a large anterior "cardiac" and a smaller posterior "pyloric." In the narrow
opening between these, three teeth (fig. 10) are set, one dorsally and one on each side. These teeth are connected with a framework of movably articulated ossicles developed as thickened and calcified portions of the lining cuticle of the stomach and moved by special muscles in such a way as to form a kind of a ─ by the middle line. The walls of the pyloric chamber bear a series of pads and ridges beset with hairs and so disposed as to form a straining apparatus.

The mid-gut is essentially the digestive and absorptive region of the alimentary canal, and its surface is, in most cases, increased by pouch-like or tubular outgrowths which not only serve as glands for the secretion of the digestive juices, but may also become filled by the more fluid portion of the pasted food, thus contributing to its absorption. These outgrowths vary much in their arrangement in the different groups. Most commonly there is a pair of lateral caeca, which may be more or less ramified and may form a massive "hepatopancreas" or gall bladder.

The whole length of the alimentary canal is provided, as a rule, with muscular fibres, both circular and longitudinal, running in its walls, and, in addition, there may be muscle-bands running between the gut and the body wall. In the region of the oesophagus these muscles are monostongous, delimiting the deglutition, and, where a gastric

Phylopoda, the antennal gland develops early and is functional during a great part of the larval life, but it ultimately atrophies, and in the adult (as in most Entomostraca) the maxillary gland is the functional excretory organ. In the Decapoda, where the antennal glands are always rudimentary, the only gland sometimes to precede it is the maxillary. In the Crustacea the maxillary gland or antenna gland is movable and may end up in the alimentary canal in certain classed Crustacea. Development shows that the glandular tube is mesoblastic in origin and is of the nature of a coelomoduct, while the end-sac is to be regarded as a vestigial portion of the coelom. In the Branchiopoda the maxillary gland is placed in the thickness of the shell-fold (if this is present) and, from this circumstance, it often receives the somewhat misleading name of "shell-gland." In the Decapoda the antennal gland is largely developed and is known as the "green gland." The external duct of this gland is often dilated into a bladder, and may even be connected in the Branchiopoda with an excretory system of sinuses ramifying through the body. The green gland and the structures associated with it in Decapoda were at one time regarded as constituting an auditory apparatus.

Nervous System.—The central nervous system is constructed on the same general plan as in the other Arthropoda, consisting of a supra-oesophageal ganglionic mass or brain, united by circumoesophageal connectives with a median thoracic ganglion, representing an anal or postabdominal ganglion. In the primitive Phylopoda the ventral chain retains the ladder-like arrangement found in some Annelids and lower worms, the two halves being widely separated and the pairs of ganglia united to form a median ganglion. Among the Crustacea, however, their morphological relations are not clear. In some cases they consist of masses of mesodermal cells, within which the excretory products appear to be stored up instead of being expelled from the body.

Circulatory System.—As in the other Arthropoda, the circulatory system in Crustacea is largely lamellose, the blood being confined to spaces or channels without definite walls. These spaces make up the apparent body-cavity, the blood passing from leaf to leaf in the primitive Arthropoda, or from cell to cell in the adult, for the most part, obliterated by the great expansion of the blood-containing spaces. The heart is of the usual Arthropodous type, lying in a more or less well-defined pericardial blood-space, with which it communicates by a pair of subcardinal openings or ostia. In the details of structure, however, great differences exist within the limits of the class. There is every reason to believe that the heart of the primitive Arthropod was tubular in form, extending the whole length of the body, and having a pair of ostia, which were probably, as in the Crustacea, retained in some of the Phylopoda, but even in that group a progressive abbreviation of the heart and diminution in length of the long axis, from the primitive condition, is exhibited. In the higher forms the two halves of the heart are more or less closely approximated and coalesced, and, in addition, a concentration of the ganglia in a longitudinal direction takes place, resulting in the formation of a heart-like mass or vessel, quite analogous to the lamellose mass of ganglionic mass representing the whole of the ventral chain. This is seen, for example, in the Brachyura among the Decapoda. The brain, or supra-oesophageal ganglion, shows various degrees of development, and in the Malacostraca is usually composed of two pairs of ganglionic centres, giving origin respectively to the antennal and antennular nerves. The centres for the antennal nerves form ganglionic swellings on the oesophageal connectives. In the higher forms, as already mentioned, the antennal ganglia have become shifted forwards and coalesced with the brain. In the Decapoda, numerous additional centres are developed in the brain and its structure becomes extremely complex.

Eye.—The eyes of Crustacea are of two kinds, the unpaired "oapad." or "nauplius" compound eye. The former is generally present in the earliest larval stages (nauplii), and in some Entomostraca, e.g. Copepoda, it forms the sole organ of vision, in the Malacostraca it is absent in the adult, and persists only in a vestigial condition, in as much as it appears in the uncoiled larva of the Astacida, and in Schizopoda. It is typically tripartite, consisting of three cup-shaped masses of pigments, the cavity of each cup being filled with columnar retinal cells. At their inner ends (towards the pigment) these cells contain the prismatic rods and the outer accessory structures may be developed in connexion with it.

The compound eyes are very similar in the details of their structure (see Arthropoda) to those of insects (Hexapoda). They consist of a large number of small sensory units, or ommatidia, each having an ommatidium. The whole organ is a transverse section of the external cuticle forming the cornea. In most cases this cornea is divided into lenticular facets corresponding to the underlying ommatidia.

Also in the compound eyes are often set on movable peduncles. It is probable that this is the primitive condition from which the sessile eyes of other forms have been derived. In the Malacostraca the sessile eyes of the crustaceans are certainly less primitive than in the typical ommatidial eyes of insects, and in some Entomostraca also there is some evidence pointing in the same direction.

Although typically paired, the compound eyes may occasionally coalesce in the middle line into a single organ. This is the case in the Cladocera among the Crustacea, with some exception in a few groups.

Eyes or Ocelli. — As in Arthropoda, the hairs or sensory cells on the surface of the body are important organs of sense and are variously modified for special sensory functions. Many, perhaps all of them
CRUSTACEA

are tactile. They are movably articulated at the base where they are inserted in pits formed by a thinning away of the cuticle, and each is supplied by a nerve-fibril. When feathered or provided with secondary barbs the setae will respond to movements or vibrations and will promptly be moved by a current of water or gas. Where setae have an auditory function. In certain divisions of the Malacostraca, more specialized organs are found which have been regarded as auditory. In the majority of the Decapoda there is a saccular auditory apparatus developed from the former antennular peduncle having on its inner surface "auditory" setae of the type just described. The sac is open to the exterior in most of the Macrura, but completely closed in the Brachyura. In the former the sac is maintained as a hollow organ and in which the discharge by the animal itself after each moult and which are supposed to act as otochests. Where the sac is completely closed it generally contains no solid particles, but in a few Macrura a single otothid seta is present as a single pair, except in some cases where Schizopoda a pair of similar otochests are found in the endopodites of the last pair of appendages (uropods). These contain each a single concretionary otothid.

As a rule, however, make it very doubtful whether aquatic Crustacea can hear at all, in the proper sense of the term, and it has been shown that one function, at least, of the so-called otochysis is connected with the equilibration of the body. They are more properly than ordinary organs.

Anatomical modification of sensory setae is supposed to be associated with the sense of smell. In nearly all Crustacea the antennules and often also the antennae bear groups of hair-like filaments in which the chitinous cuticle is extremely delicate and which do not take up the forma of tubular canals. In a large number of filaments or aesthetascs. They are very often more strongly developed in the male sex, and are supposed to guide the males in pursuit of the females.

Gills.—In addition to the digestive and excretory glands already mentioned, various glandular structures occur in the different groups of Crustacea. The most important of these belong to the category of derrnal glands, and may be scattered over the surface of the body and may be found in glandular masses. In certain cases they discharge special functions. Such glands occurring on the upper and lower lips or on the walls of the oesophagus have been regarded as salivary. In some Amphipoda the secretion of glands on the body and limbs is often modified into a tubular canals, which then appear as filaments or aesthetascs. In certain Amphipoda and Branchiura, are believed to have a poisonous function. Possibly related to the same group of structures are the greatly-developed cement-glands of the Cirripedia, which serve to attach the animals to their support.

Phosphenotic Organs.—Many Crustacea belonging to very different groups (Ostracoda, Copepoda, Schizopoda, Decapoda) possess the power of emitting light. In the Ostracoda and Copepoda the organ of luminous reception, as is due to the coeloms, which produce a luminous secretion, and this is the case also in certain members of the Schizopoda and Decapoda. In other cases in the last two groups, however, the light-producing organs found on the appendages, together with a coelomic space or space which were formerly described as accessory eyes. Each consists of a globular capsule pierced at one or two points for the entrance of nerves which end in a central cup-shaped "striated body." This body is carried to an extreme degree, and the minute body is attached behind it a reflector formed of concentric lamellae, while, in front, in some cases, there is a refracting lens. The whole organ can be rotated by special muscles. Organs of this type are best known in the Euphausiidae among the Antarctic, but a modified form is found in some of the Lower Cephalopoda.

Reproductive System.—In the great majority of Crustacea the sexes are separate. Apart from certain doubtful and possibly abnormal instances, males and females are usually found to be associated with sexual reproduction in many among the Crustacea, and are on the same sex, the female being either a male or a female. Where the sexes are distinct, a more or less marked dimorphism often occurs. The male is often provided with clasping organs for seizing the female. These may be formed by the modification of almost any of the appendages, often the antennules or antennae or some of the thoracic appendages, or even the mandibular palp (some Ostracoda). In addition, some of the appendages in the neighbourhod of the genital apertures may be modified for the purpose of transferring the genitalic products to the female, as, for instance, the first and second endopods of the Decapoda. In the higher Decapoda, the male is generally larger than the female and has stronger chelae. On the other hand, in other groups the male is often smaller than the female. In the parasitic Copepoda and Isopoda the disparity in size is carried to an extreme degree, and the minute male is attached, like a parasite, to the enormously larger female.

The Cirripedia present some examples of sexual relationships which are only parallel in the animal kingdom, among the parasitic Myzostomida. While the great majority are simple hermaphrodites, capable of cross and self-fertilization, it was discovered by Darwin that in certain species, minute degraded males exist, attached within the mantle-cavity of the ordinary individuals, and are entirely dependent on the dwarf males for fertilization. In spite of the opinion of some distinguished zoologists to the contrary, it seems most probable that the separation of the sexes is in this case a secondary condition, derived from hermaphroditism through the intermediate stage represented by each sex having complemental males.

The gonads, as in other Arthropoda, are hollow sacular organs, the cavity communicating with the efferent ducts. They are primitively paired, but often coalesce with each other more or less completely. In a few cases, however, there may be one genus of parasitic Isopoda (Heminothous), with two pairs of oviducts are found. Various accessory structures may be connected with the efferent ducts in both sexes. The oviducts may have diverticula serving as receptacles for the spermatozoa (in cases with internal impregnation takes place), and may be provided with glands secreting envelopes or shells around the eggs. The male ducts often have glandular walls, secreting capsules or spermatophores within which the spermatozoa are packed for transference to the female. The terminal part of the male ducts may be protrusible and act as an intromittent organ, or this function may be discharged by some of the appendages, as, for instance, in the Brachyura.

The position of the genital apertures varies greatly in the Crustacea. In the Crustacea of the Trematoidea and most of the Crustacea of the Cirripedia, where the openings are on the first thoracic (fourth postoral) somite. The most posterior position is occupied by the genital apertures of certain Phyllopoda (Polyartemia), which lie behind the thirteenth trunk-somite. It is common to the Digenea of the Malacostraca that the genital apertures is constantly different in the two sexes, the female openings being on the sixth, and those of the male on the eighth thoracic somite.

Very few Crustacea are viviparous in the sense that the eggs are retained within the body until hatching takes place (some Phyllopoda), but, on the other hand, the great majority carry the eggs in some way or other after their extrusion. In some Phyllopoda (Aplysides) the eggs are formed by modification of certain of the thoracic feet. The eggs are retained between the valves of the shell in some Phyllopoda and in the Cladocera and Ostracoda, and they lie in the mantle cavity in the Cirripeda. In the Copepoda they are agglutinated together into masses attached to the body of the female. Among the Malacostraca some Schizopoda, the Cumacea, Tanainacidae, Isopoda and Amphipoda (sometimes grouped together as Peracarida) have a marsupium or broad-pouch formed by overlapping plates attached to the bases of some of the thoracic legs. In most of the Decapoda the eggs are carried by the female, attached to the abdominal appendages (fig. 11). A few cases are known in which the developing embryos are nourished by a special secretion while in the brood-cavity of the mother (Cladocera, terrestrial Isopoda).

Embryology.

The majority of the Crustacea are hatched from the egg in a form differing more or less from that of the adult, and pass through a series of free-swimming larval stages. There are many cases, however, in which the metamorphosis is suppressed, and the newly-hatched young resemble the parent in general structure. The relative size of the eggs and the amount of nutritive yolk which they contain are generally much greater in those forms which have a direct development.

The details of the early embryonic stages vary considerably within the limits of the class. They are of interest, however, rather from the point of view of general embryology than from that of

FIG. 11.—Side view of Crab, the abdomen extended and carrying a mass of eggs beneath it; e, egg sacs. (After Morse.)
the special student of the Crustacea, and cannot be fully dealt with here.

Segmentation is usually of the superficial or centrotelochial type. The teloblast is formed either by a definite invagination or by the immigration of isolated cells, known as vitellophages, which wander through the yolk and later become associated into a definite mesenteron, or by some combination of these two methods. The blastopore generally occupies a position corresponding to the posterior end of the body. The teloblast of the exphyletic (naupliar) region probably arises in connexion with the lips of the blastopore and consists of loosely-connected cells or mesenchyme. In the region of the trunk, in many cases, paired mesoblastic bands are formed, growing in length by the division of teloblastic cells at the posterior end, and becoming segmented into somites. The existence of true coelom-

sacs is somewhat doubtful. The rudiments of the first three pairs of appendages commonly appear simultaneously, and, even in forms with embryonic development, they show differences in their mode of appearance from the succeeding somites. Further, a definite cuticular membrane is frequently formed and shed at this stage, which corresponds to the nauplius-stage of larval development.

The larval metamorphoses of the Crustacea have attracted much attention, and have been the subject of much discussion in view of their bearing on the phylogenetic history of the group. In those Crustacea in which the series of larval stages is most complete, the starting-point is the form already mentioned under the name of nauplius. The typical nauplius (fig. 12) has an oval unsegmented body and three pairs of limbs corresponding to the antennules, antennae and mandibles of the adult. The antennules are uniramous, the others biramous, and all three pairs are used in swimming.

**Fig. 12.—Nauplius of a Prawn (Penaeus). (Fritz Müller).**

The antennae have a spiniform or hooked masticatory process at the base, and share with the mandibles, which have a similar process, the function of seizing and masticating the food. The mouth is overhung by a large labrum or upper lip, and the integument of the dorsal surface of the body forms a more or less definite dorsal shield. The paired eyes are, as yet, wanting, but the unpaired eye is large and conspicuous. A pair of frontal papillae or filaments, probably sensory, are commonly present.

A naupliar larva differing only in details from the typical form just described is found in the majority of the Phyllopoda, Copepoda and Ciri pedia, and in a more modified form, in some Ostracoda. Among the Malacostraca the nauplius is less commonly found, but it occurs in the Euphausiidae among the Schizopoda and in a few of the more primitive Decapoda (Penaeidae) (fig. 12). In most of the Crustacea which hatch at a later stage there is, as already mentioned, more or less clear evidence of an embryonic nauplius stage. It seems certain, therefore, that the production of a nauplius larva must be regarded as a very primitive character of the Crustacea stock.

As development proceeds, the body of the nauplius elongates, and indications of segmentation begin to appear in its posterior part. At successive moults the somites increase in number, new somites being added behind those already differentiated, from a formative zone in front of the telsonic region. Very commonly the posterior end of the larva is forked, two processes growing out at the sides of the anus and often persisting in the adult as the "caudal furca." The appendages posterior to the mandibles appear as buds on the ventral surface of the somites, and in the most primitive cases they become bilobed, like the somites which bear them, in regular order from before backwards. The limb-buds early become bilobed and grow out into typical biramous appendages which gradually assume the characters found in the adult. With the elongation of the body, the dorsal shield begins to project posteriorly as a shell-fold, which may increase in size to envelop more or less of the body or may disappear altogether. The rudiments of the paired eyes appear under the integument at the sides of the head, but only become pedunculated at a comparatively late stage.

The course of development here outlined, in which the nauplius gradually passes into the adult form by the successive addition of somites and appendages in regular order, agrees so well with the process observed in the development of the typical Annelida that we must regard it as being the most primitive method. It is most closely followed by the Phyllopods such as *Apsis* or *Branchipus*, and by some Copepods.

In most Crustacea, however, this primitive scheme is more or less modified. The earlier stages may be suppressed or passed through

**Fig. 13.—Early Stages of Balanus. (After Spence Bate.)**

B, Cypris-larva, a bivalve shell and just before becoming attached (represented with cilia extended). D, Later stage, viewed from above. E, Side view, later stage and with B, where it is attached.

The dots indicate the actual size within the egg (or within the maternal brood-chamber), so that the larva, on hatching, has reached a stage more advanced than the nauplius. Further, the gradual appearance and differentiation of the successive somites and appendages may be accelerated, so that comparatively great advances take place at a single moult. In the Cirripedia, for example, the latest nauplius stage (fig. 13, A) gives rise directly to the so-called *Cypris*-larva (fig. 13, B), differing widely from the nauplius in form, and possessing all the appendages of the adult. Another very common modification of the primitive method of development is found in the accelerated appearance of certain somites or appendages, disturbing the regular order of development. This modification is especially found in the Malacostraca. Even in those which have most fully retained the primitive order of development, as in the *Penaeidae* and *Euphausiidae*, the last pair of abdominal appendages make their appearance in advance of those immediately in front of them. The same process, carried further, leads to the very peculiar larva known as the *Zoea*, in the typical form of which, found in the *Brachyura* (fig. 14), the posterior five or six thoracic somites have their development greatly retarded, while are still represented by a short unsegmented region of the body at a time when the abdominal somites are fully formed and even carry appendages. The *Zoea* was formerly regarded as a recapitulation of an ancestral form, but there can be no doubt that its peculiarities are the result of secondary modification. It is most typically developed in the most specialized Decapoda, the Brachyura, while the more primitive groups of Malacostraca, the *Euphausiidae*, *Penaeidea* and Stomatopoda, retain the primitive order of appearance

**Fig. 14.—Zoea of Common Shore-Crab in its second stage. (Spence Bate.)**

of the somites, and, for the most part, of the limbs. At the same time, the tendency to a retardation in the development of the posterior thoracic somites is very general in Malacostraca larvae, and may perhaps be correlated with the fact that in the primitive Phyllocarida the whole thoracic region is very short and the limbs closely crowded together.

Besides the nauplius and the zoea there are many other types of Crustacean larvae, distinguished by special names, though, as their occurrence is restricted within the limits of the smaller systematic groups, they are of less general interest. We may mention the Mysis-stage (better termed Schizopod-stage) found in many Macrura (as, for example, the lobster), which differs from the adult in having large natatory exopodites on the thoracic legs.

Most of the larval forms swim freely at the surface of the sea, and many show special adaptations to this habit of life. As in many other "pelagic" organisms, spines and processes from the surface of the body are often developed, which are probably less important as defensive organs than as aids to flotation. This is well seen in the nauplii of many Cirripedia (fig. 15) and in nearly all zoae. Perhaps the most striking example is the zoea-like larva of the Sergestidae. This has an extraordinary armature of ramified spines. The same purpose is probably served by the extreme flattening of the body in the membranous Phyllosoma-larva of the rock-lobsters and their allies (Loricata).

**Post History.**

Although fossil remains of Crustacea are abundant, from the most ancient fossiliferous rocks down to the most recent, their study has hitherto contributed little to a precise knowledge of the phylogenetic history of the class. This is partly due to the fact that many important forms must have escaped fossilization altogether owing to their small size and delicate structure, while very many of those actually preserved are known only from the carapace or shell, the limbs being absent or represented only by indecipherable fragments. Further, many important groups were already differentiated when the geological record began. The Phyllopoda, Ostracoda and Cirripedia (Thyrostraca) are represented in Cambrian or Silurian rocks by forms which seem to have resembled closely those now existing, so that palaeontology can have little light to throw on the mode of origin of these groups. With the Malacostraca the case is little better. There is considerable reason for believing that the Ceratiocaridae, which are found from the Cambrian onwards, were allied to the existing Nebalia, and may possibly include the forerunners of the true Malacostraca, but nothing is definitely known of their appendages. In Palaeozoic formations, from the Upper Devonian onwards, numbers of shrimp-like forms are found which have been referred to the Schizopoda and the Decapoda, but here again the scanty information which may be gleaned as to the structure of the limbs barely permits of definite conclusions as to their affinities. The recent discovery in the Tasmanian "schizopod" Anaspides, of what is believed to be a living representative of the Carboniferous and Permian Syncarida, has, however, afforded a clue to the affinities of some of these problematical forms.

True Decapods are first met with in Mesozoic rocks, the first to appear being the Penaeidea, a primitive group comprising the Penaeidae and Sergestidae, which occur in the Jurassic and perhaps in the Trias. Some of the earliest are referred to the existing genus Penaeus. The Stenopidae, another primitive group, differing from the Penaeidea in the character of the gills, appear in the Trias and Jurassic. The Caridea or true shrimps and shrimps appear later, in the Upper Jurassic, some of them presenting primitive characteristics in the retention of swimming exopodites on the walking-legs. The Eryonidea (fig. 16, a), a group related to the Loricata but of a more generalized type, are specially interesting since the few existing deep-sea forms appear to be only surviving remnants of what was, in the Mesozoic period, a dominant group. The Mesozoic Glyphaenidae have been supposed to stand in the direct line of descent of the modern rock-lobsters and their allies (Loricata). Some of the Loricata have persisted with little change from the Cretaceous period to the present day.

The Anomura are hardly known as fossils. The Brachyura, on the other hand, are well represented (fig 16, 1, 2). The earliest forms, from the Lower Oolite and later, belonging chiefly to the extinct family Prospomponidae, have been shown to have close relations with the most generalized of existing Brachyura, the deep-sea Homolodromiidae, and to link the Brachyura to the Homarine (lobster-like) Macrura.

A few Isopoda are known from Secondary rocks, but their systematic position is doubtful and they throw no light on the evolution of the group. The Amphipoda are not definitely known to occur till Tertiary times. Stomatopoda of a very modern-looking type, and even their larvae, occur in Jurassic rocks.

In the dearth of trustworthy evidence as to the actual forerunners of existing Crustacea, we are compelled to rely wholly on the data afforded by comparative anatomy and embryology in attempting to reconstruct the probable phylogeny of the class. It is unnecessary to insist on the purely speculative character of the conclusions to be reached in this way, so long as they cannot be checked by the results of palaeontology, but, when this is recognized, such speculation is not only legitimate but necessary as a basis on which to build a natural classification.

The first attempts to reconstruct the genealogical history of the Crustacea started from the assumption that the "theory of recapitulation" could be applied to their larval history. The various larval forms, especially the nauplius and zoea, were supposed to reproduce, more or less closely, the actual structure of ancestral types. So far as the zoea was concerned, this assumption was soon shown to be erroneous, and the secondary nature of this type of larva is now generally admitted. As regards the nauplius, however, the constancy of its general character in the most widely diverse groups of Crustacea strongly suggests that it is a very ancient type, and the view has been advocated that the Crustacea must have arisen from an unsegmented nauplius-like ancestor.

' The objections to this view, however, are considerable. The resemblances between the Crustacea and the Annelid worms, in such characters as the structure of the nervous system and the mode of growth of the somites, can hardly be ignored. Several structures which must be attributed to the common
stock of the Crustacea, such as the paired eyes and the shell-fold, are not present in the nauplius. The opinion now most generally held is that the primitive Crustacean type is most nearly approached by certain Phyllopods such as _Aplys_. The large number and the uniformity of the trunk somites and their appendages, and the structure of the nervous system and of the heart in _Aplys_, are Annelidan characters which can hardly be without significance. It is probable also, as already mentioned, that the leaf-like appendages of the Phyllopoda are of a primitive type, and attempts have been made to refer their structure to that of the Annelid parapodium. In many respects, however, the Phyllopoda, and especially _Aplys_, have diverged considerably from the primitive Crustacean type. All the cephalic appendages are much reduced, the mandibles have no palps, and the maxillulae are vestigial. In these respects some of the Copepoda have retained characters which we must regard as much more primitive. In those Copepods in which the palps of the mandibles as well as the antennae are biramous and natatory, the first three pairs of appendages retain throughout life, with little modification, the shape and function which they have in the nauplius stage, and must, in all likelihood, be regarded as appendages derived from those of the primitive Crustacea. In other respects, however, such as the absence of paired eyes and of a shell-fold, as well as in the characters of the post-oral limbs, the Copepoda are undoubtedly specialized.

In order to reconstruct the hypothetical ancestral Crustacean, therefore, it is necessary to combine the characters of several of the existing groups. It may be supposed to have approximated, in general form, to _Aplys_, with an elongated body composed of numerous similar somites and terminating in a caudal furca; with the post-oral appendages all similar and all bearing gnathobasic processes; and with a carapace originating as a shell-fold from the maxillary somite. The eyes were probably stalked, the antennae and mandibles biramous and natatory, and both armed with masticatory processes. It is likely that the trunk-limbs were also biramous, with additional endites and exites. Whether any of the obscure fossils generally referred to the Phyllopoda or Phyllocarida may have approximated to this hypothetical form it is impossible to say. It is to be noted, however, that the Triobita, which, according to the classification here given, are dealt with under Arachnida, have been removed, except in such characters as the absence of a shell-fold and of eye-stalks, from the primitive Crustacean here sketched.

On this view, the nauplius, while no longer regarded as reproducing an ancestral type, does not altogether lose its phylogenetic significance. It is an ancestral larval form, corresponding perhaps to the stages immediately succeeding the trochophere in the development of Annelids, but with some of the later-acquired Crustacean characters superposed upon it. While little importance is to be given to such characters as the unsegmented body, the small number of limbs and the absence of a shell-fold and of paired eyes, it has, on the other hand, preserved archaic features in the form of the limbs and the masticatory function of the antenna.

The probable course of evolution of the different groups of Crustacea from this hypothetical ancestral form can only be touched on here. The Phyllopoda must have branched off very early and from them the Cladocera the way is clear. The Ostracoda might have been derived from the same stock were it not that they retain the mandibular palp which all the Phyllopoda have lost. The Copepoda must have separated themselves very early, though perhaps some of their characters may be persistently larval rather than phylogenetically primitive. The Cirripedia are so specialized both as larvae and as adults that it is hard to say in what direction their origin is to be sought.

For the Malacostraca, it is generally admitted that the Leptostraca (Nebalia, &c.) provide a connecting-link with the base of the Phyllopod stem. Nearest to them come the Schizopoda, a primitive group from which two lines of descent go, one leading from the Mysidacea (Mysidae + Lophogastridae) to the Cumacea and the sessile-eyed groups Isopoda and Amphipoda, the other from the Euphausiacea (Euphausiidae) to the Decapoda.

**Classification.**

The modern classification of Crustacea may be said to have been founded by P. A. Latreille, who, in the beginning of the 19th century, divided the class into Entomostraca and Malacostraca. The latter division, characterized by the possession of 19 somites and pairs of appendages (apart from the eyes), by the division of the appendages into two tagmata corresponding to cephalothorax and abdomen, and by the constancy in position of the generative apertures, differing in the two sexes, is unquestionably a natural group. The Entomostraca, however, are certainly a heterogeneous assemblage, defined only by negative characters, and the name is retained only for the sake of convenience, just as it is often useful to speak of a still more heterogeneous and unnatural assemblage of animals as Invertebrata. The barnacles and their allies, forming the group Cirripedia or Thyrostraca, sometimes treated as a separate sub-class, are distinguished by being sessile in the adult state, the larval antennules serving as organs of attachment, and the antenna being lost. An account of them will be found in the article Thyrostraca. The remaining groups are dealt with under the headings Entomostraca and Malacostraca, the annectent group Leptostraca being included in the former.

It may be useful to give here a synopsis of the classification adopted in this encyclopaedia, noting that, for convenience of treatment, it has been thought necessary to adopt a grouping not always expressive of the most recent views of affinity.

**Class Crustacea.**

Sub-class Entomostraca.

Order Branchiopoda.

Sub-orders Phyllopoda, Cladocera, Branchiura.

Orders Ostracoda, Copepoda.

Sub-classes Thyrostraca (Cirripedia), Leptostraca, Malacostraca.

Order Decapoda, Branchyura.

Orders Schizopoda (including Anaspidae), Stomatopoda, Symphyla (Cumacea), Isopoda (including Tanaidacea), Amphipoda.

(W. T. CA.)

**CRUSTUMERIUM,** an ancient town of Latium, on the edge of the Sabine territory, near the headwaters of the Allia, not far from the Tiber. It appears several times in the early history of Rome, but was conquered in 300 B.C. according to Livy ii. 10, the tribus Crustumina [or Clustumina] being formed in 471 B.C. Pliny mentions it among the lost cities of Latium, but the name clung to the district, the fertility of which remained famous. No remains of it exist, and its exact site is uncertain.

See T. Ashby in *Proceedings of the British School at Rome*, iii. 50.

**CRUVEILHIER, JEAN** (1751–1784), French anatomist, was born at Limoges in 1751, and was educated at the university of Paris, where in 1782 he became professor of anatomy. In 1786 he became the first occupant of the recently founded chair of pathological anatomy. He died at Jussac in 1784. His chief works are *Anatomie descriptive* (1834–1836); *Anatomie pathologique du corps humain* (1829–1842), with many coloured plates; *Traité d'anatomie pathologique générale* (1840–1864); *Anatomie du système nerveux de l'homme* (1845); *Traité d'anatomie descriptive* (1851).

**CRUZ E SILVA, ANTONIO DINIZ DA** (1731–1799), Portuguese heroic-comic poet, was the son of a Lisbon carpenter who emigrated to Brazil shortly before the poet’s birth, leaving his wife to support and educate her young family by the earnings of her needle. Diniz studied Latin and philosophy with the Oratorians, and in 1747 matriculated at Coimbra University, where he wrote his first verses about 1750. In 1753 he took his degree in law, and returning to the capital, devoted much of the
next six years to literary work. In 1756 he became one of the founders and drew up the statutes of the Arcadia Lusitana, a literary society whose aims were the instruction of its members, the cultivation of the art of poetry, and the restoration of good taste. The fault was not his if these ends were not attained, for, taking contemporary French authors as his models, he contributed much, both in prose and verse, to its proceedings, until he left in February 1760 to take up the position of juiz de fora at Castello de Vide. On returning to Lisbon for a short visit, he found the Arcadia a prey to the internal dissensions that caused its dissolution in 1774, but succeeded in composing them, and in 1764 he went to Elvas to act as auditor of one of the regiments stationed there. During a ten years' residence, his wide reading and witty conversation gained him the friendship of the governor of that fortress and the admiration of a circle comprising all that was cultivated in Elvas. As in most cathedral and garrison towns, the clerical and military elements dominated society, and here were mutually antagonistic, because of the enmity between their respective leaders, the bishop and the governor. Moreover, Elvas, being a remote provincial centre, abounded in curious and grotesque types. Diniz, who was a keen observer, noted these, and, treating them in his memory, reproduced them, with their vanities, intrigues and ignorance, in his masterpiece, Hyssopæ. In 1766 a quarrel arose between the bishop and the prior of the cathedral, and the matter came before the bishop, who decided in favour of the former. The prior received his sentence outside the church from the bishop, who was a private person of the cathedral, instead of at the principal entrance. The matter being one of principle, neither party would yield what he considered his rights, and it led to a lawsuit, and divided the town into two sections, which eagerly debated the arguments on both sides and enjoyed the ridiculous incidents which accompanied the dispute. Ultimately the dean died, and was succeeded by his nephew, who appealed to the crowned head with success and the bishop lost his pretension. The Hyssopæ arose out of and deals with this affair. It was dictated in seventeen days, in the years 1770-1772, and, in its final redaction, consists of eight cantos of blank verse. The purpose of absolutism left open only one form of expression, satire, and in this poem Diniz produced an original work which ridicules the clergy and the prevailing Gallo-Mauryan, and contains episodes full of humour. It has been compared with Boileau's Lettres, because both are founded on a petty ecclesiastical quarrel, but here the resemblance ends, and the poem of Diniz is the superior in everything except metrication.

In 1770 he went to Lisbon in 1774, Diniz endeavoured once more to resuscitate the Arcadia, but his long absence had withdrawn its chief support, its most talented members Garçao (q.v.) and Quita were no more, and he only assisted at its demise. In April 1776 he was appointed desembargador of the court of Relação in Rio de Janeiro and given the habit of Aviz. He lived in Brazil, devoting his leisure to a study of its natural history and mineralogy, until 1789, when he went back to Lisbon to take up the post of desembargador of the Relação of Oporto; in July 1790 he was promoted, and became desembargador of the Casa da Suplicação. In this year he was sent again to Brazil to assist in trying the leaders of the Republican conspiracy in Minas, in which Gonzaga (q.v.) and other men of letters were involved, and in December 1792 he became chancellor of the Relação in Rio. Six years later he was named councillor of the Conselho Ultramarino, but did not live to return home, dying in Rio on the 5th of October 1799.

Diniz possessed a poetic temperament, but his love of imitating the classics, whose spirit he failed to understand, fettered his muse, and he seems never to have perceived that mythological comparisons and pastoral allegories were poor substitutes for the expression of natural feeling. The conventionalism of his art prejudiced its sincerity, and, inwardly cherishing the belief that poetry was unworthy of the dignity of a judge, he never gave his real talents a chance to display themselves. His Anacreontic odes, dithyrambs and idylls earned the admiration of contemporaries, but his Pindaric odes lack fire, his sonnets are weak, and his idylls have neither the truth nor the simplicity of Quita's work. As a rule Diniz's versification is weak and his verses lack harmony, though the diction is beyond cavil.

His poems were published in 6 vols. (Lisbon, 1807-1817). The best edition of Hysopæ, to which Diniz owes his lasting fame, is that of J. R. Coelho (Lisbon, 1879), with an exhaustive introductory study on his life and writings. A French prose version of the poem by Boissonade has gone through two editions (Paris, 1828 and 1867), and English translations of selections have been printed in the Foreign Quarterly Review, and in the Manchester Quarterly (April 1896).

**CRYOLITE, a mineral discovered in Greenland by the Danes in 1794, and found to be a compound of fluorine, sodium and aluminium. From its general appearance, and from the fact that it melts readily, even in a candle-flame, it was regarded by the Eskimos as a peculiar kind of ice; from this fact it acquired the name of cryolite (from Gr. κρύος, frost, and ἄλας, stone). Cryolite occurs in colourless or snow-white cleavable masses, often tinted brown or red with iron oxide, and occasionally passing into a black variety. It is usually translucent, becoming nearly transparent on immersion in water. The mineral cleaves in three rectangular directions, and the crystals occasionally found in the crevices have a cubic habit, but it has been proved, after much discussion, that they belong to the anorthic system. The cryolite is a hydrous sodium aluminium fluoride, having the formula NaAlF₄, or 3NaF·AlF₃, corresponding to fluorine 54.4, sodium 32.8, and aluminium 12.8%. It colours a flame yellow, through the presence of sodium, and when heated with sulphuric acid it evolves hydrofluoric acid.

Cryolite occurs almost exclusively at Ivtigtut (sometimes written Evigtok) on the Arksut Fjord in S.W. Greenland. There it forms a large deposit, in a granitic vein running through gneiss, and is accompanied by quartz, siderite, galena, blende, chalcopyrite, &c. It is also associated with a group of kindred minerals, some of which are evidently products of alteration of the cryolite, known as pachnolite, thomsonolite, ralstonite, gerskuvite, arkosite, &c. The cryolite likewise occurs, though only to a limited extent, at Miyask, in the Ilmen Mountains; at Pike's Peak, Colorado, and in the Yellowstone Park.

Cryolite is a mineral of much economic importance. It has been extensively used as a source of metallic aluminium, and as a flux in smelting the metal. It is largely employed in the manufacture of certain sodium salts, as suggested by Julius Thomsen, of Copenhagen, in 1849; and it has been used for the production of certain kinds of porcelain, and glass, remarkable for its toughness, and for enamelled ware.

Although cryolite is known as "ice-stone" (Eisstein), it is not to be confused with "ice-spar" (Eispath), which is a vitreous kind of felspar termed "glassy felspar" or rhacolite. (F. W. R.*)

**CRYPT** (Lat. crypta, from the Gr. κρυπτή, to hide), a vault or subterranean chamber, especially under churches. In classical phraseology "crypta" was employed for any vaulted building, either partially or entirely below the level of the ground. It is used for a sewer (crypta Suburae, Juvenal, Sat. v. 106); for the "carceres," or vaulted stalls for the horses and chariots in a circus (Sidon. Apoll. Corn. xxii. 319); for the close porticoes or arcades, more fully known as "cryptoporicus," attached by the Romans to their suburban villas for the sake of coolness, and to the theatres as places of exercise or rehearsal for the performers (Plin. Epist. ii. 15, v. 6, vii. 21; Sueton. Calig. 58; Sidon. Apoll. lib. ii. epist. 2); and for underground receptacles for agricultural produce (Vitr. vi. 8, Varro, De rust. i. 57). Tunnels, or galleries excavated in the living rock, were also called cryptae. Thus the tunnel to the north of Naples, through which the road passes to Puteoli, famous among tourists as the "Grotto of Posilipo," was originally designated crypta Neapolitana (Seneca, Epist. 57). In early Christian times crypta was appropriately employed for the galleries of a catacomb, or for the catacomb itself. Jerome calls them by this name when describing his visits to them as a schoolboy, and the term is used by Prudentius (see CATACOMBS).
A crypt, as a portion of a church, had its origin in the subterranean chapels known as "confessionals," erected around the tomb of a martyr, or the place of his martyrdom. This is the origin of the spacious crypts, some of which may be considered subterranean churches, of the Roman churches of S. Prisca, S. Prassede, S. Martino ai Monti, S. Lorenzo fuori le Mura, and above all of St Peter's—the crypt being thus the germ of the church or basilica subsequently erected above the hallowed spot. When the martyr's tomb was sunk in the surface of the ground, and not placed in a catacomb chapel, the original memorial-shrine would be only partially below the surface, and consequently the part of the church erected over it, which was always that containing the altar, would be elevated some height above the ground, and be approached by flights of steps. This fashion of raising the chancel or altar end of a church on a crypt was widely imitated long after the reason for adopting it ceased, and even where it never existed. The crypt under the altar at the basilica of St Maria Maggiore in Rome is merely imitative, and the same may be said of many of the crypts of the early churches in England. The original Saxon cathedral of Canterbury had a crypt beneath the eastern apse, containing the so-called body of St Dunstan, and other relics, "fabricated," according to Eadmer, "in the likeness of the confessional of St Peter at Rome." (See Basilica). St Wilfrid constructed crypts still existing beneath the churches erected by him in the latter part of the 7th century at Hexham and Ripon. These are peculiarly interesting from their similarity in form and arrangement to the catacomb chapels with which Wilfrid must have become familiar during his residence in Rome. The cathedral, begun by Æthelwold and finished by Alphège at Winchester, at the end of the 10th century, had spacious crypts "supporting the holy altar and the venerable relics of the saints" (Wulstan, Life of St. Æthelwold), and they appear to have been common in the earlier churches in England. The arrangement was adopted by the Norman builders of the 11th and 12th centuries, and though far from universal is found in many of the cathedrals of that date. The object of the construction of these crypts was twofold—to give the altar sufficient elevation to enable those below to witness the sacred mysteries, and to provide a place of burial for those holy men whose relics were the church's most precious possession. But the crypt was "a foreign fashion," derived, as has been said, from Rome, "which failed to take root in England, and indeed elsewhere barely outlasted the Romanesque period." (Essays on Cathedrals, ed. Howson, p. 331).

"Some crypts beneath English Norman cathedrals, that under the choir of Canterbury (q.e.) is by far the largest and most elaborate in its arrangements. It is, in fact, a subterranean church of vast size and considerable altitude. The whole crypt was dedicated to the Virgin Mary, and contained two chapels especially dedicated to her,—the central one beneath the high altar, enclosed with rich Gothic screen-work, and one under the south transept. This latter chapel was appropriated by Queen Elizabeth to the use of the French Huguenot refugees who had settled at Canterbury in the time of Edward VI. There were also in this crypt a large number of altars and chapels of other saints, some of whose hallowed bodies were buried here. At the extreme east end, beneath the Trinity chapel, the body of St Thomas (Becket) was buried the day after his martyrdom, and lay there till his translation, July 7, 1220.

The cathedrals of Winchester, Worcester and Gloucester have crypts of slightly earlier date (they may all be placed between 1080 and 1100), but of similar character, though less elaborate. They all contain piscinas and other evidences of the existence of altars in considerable numbers. They are all apsidal. The most picturesque is that of Worcester, the work of Bishop Wulstan (1084), which is remarkable for the multiplicity of small pillars supporting its radiating vaults. Instead of having the air of a sepulchral vault like those of Winchester and Gloucester, this crypt is, in Professor Willis's words, "a complex and beautiful temple." Archbishop Roger's crypt at York, belonging to the next century (1154-1181), was filled up with earth when the present choir was built at the end of the 14th century, and its existence forgotten till its disinterment after the fire of 1829. The choir and presbytery at Rochester are supported by an extensive crypt, of which the western portion is Gundulf's work (1076-1107), but the eastern part, which displays slender cylindrical and octagonal shafts, with light vaulting springing from them, is of the same period as the superstructure, the first years of the 13th century. This crypt, and that beneath the Early English Lady chapel at Hereford, are the latest English existing cathedral crypts. That at Hereford was rendered necessary by the fall of the ground, and is an exceptional case. Later than any of these crypts was that of St Paul's, London. This was a really large and magnificent church of Decorated date, with a vaulted roof of rich and intricate character resting on a forest of clustered columns. Part of it served as the parish church of St Faith. A still more exquisite work of the Decorated period is the crypt of St Stephen's chapel at Westminster, than which it is difficult to conceive anything more perfect in design or more elaborate in ornamentation. Having happily escaped the conflagration of the Houses of Parliament in 1834—before which it was degraded to the purpose of the speaker's state dining-room—it has been restored to its former sumptuousness of decoration, and is now one of the most beautiful architectural gems in England.

Of the English cathedrals the only one that possesses a crypt is the cathedral of Glasgow, rendered celebrated by Sir Walter Scott in his novel of Rob Roy (ch. xx.). At the supposed date of the tale, and indeed till a comparatively recent period, this crypt was used as a place of worship by one of the three congregations among which the cathedral was partitioned, and was known as "the Laigh or Barony Kirk." It extends beneath the choir transepts and chapter-house; in consequence of the steep declivity on which the cathedral stands it is of unusual height and lightnessomeness. It belongs to the 13th century, its style corresponding to Early English, and is simply constructional, the building being adapted to the locality. In architectural beauty it is quite unequalled by any crypt in the United Kingdom, and can hardly anywhere be surpassed. It is an unusually rich example of the style, the clustered piers and groining being exquisite in design and admirable in execution. The bosses of the roof and capitals of the piers are very elaborate, and the doors are much enriched with foliage. "There is a solidity in its architecture, a richness in its vaulting, and a variety of perspective in the spacing of its pillars, which make it one of the most perfect pieces of architecture in these kingdoms." (Fergusson).

Of the centre of the main aisle stands the mutilated effigy of St Mungo, the patron saint of Glasgow, and at the south-east corner is a well called after the same saint.

Crypts under parish churches are not very uncommon in England, but they are usually small and not characterized by any architectural beauty. A few of the earlier crypts, however, deserve notice. One of the earliest and most remarkable is that of the church of Lastingham near Pickering in Yorkshire, on the site of the monastery founded in 648 by Cedid, bishop of the East Saxons. The existing crypt, though exceedingly rude in structure, is of considerably later date than Bishop Cedd, forming part of the church erected by Abbot Stephen of Whitby in 1080, when he had been driven inland by the incursions of the northern pirates. This crypt is remarkable from its extending under the nave as well as the chancel of the upper church, the plan of which it accurately reproduces, with the exception of the westernmost bay. It forms a nave with side aisles of three bays, and an apsidal chancel, lighted by narrow deeply splayed slits. The roof of quadripartite vaulting is supported by four very dwarf thick cylindrical columns, the capitals of which and of the responds are clumsy imitations of classical work with rude volutes. Still more curious is the crypt beneath the chancel of the church of Repton in Derbyshire. This also consists of a centre and side aisles, divided by three arches on either side. The architectural character, however, is very different from that at Lastingham, and is in some respects almost unique, the
pier's being slender, and some of them of a singular spiral form, with a bead running in the sunken part of the spiral. Another very extensive and curious Norman crypt is that beneath the chancel of St Peter's-in-the-East at Oxford. This is five bays in length, the quadripartite vaulting being supported by eight low, somewhat slender, cylindrical columns with capitals bearing grotesque animal and human subjects. Its dimensions are 36 by 20 ft. and 10 ft. in height. This crypt has been commonly attributed to Gymboldt in the 10th century; but it is really not very early Norman. Under the church of St Mary-le-Bow in London there is an interesting Norman crypt not very dissimilar in character to that last described. Of a later date is the remarkably fine Early English crypt groin'd in stone, beneath the chancel of Hythe in Kent, containing a remarkable collection of skulls and bones, the history of which is quite uncertain. There is also a Decorated crypt beneath the chancel at Wimborne minster, and one of the same date beneath the southern chancel aisle at Grantham.

Among the more remarkable French crypts may be mentioned those of the cathedrals of Auxerre, said to date from the original foundation in 1085; of Bayeux, attributed to Odo, bishop of that see, uterine brother of William the Conqueror; of St George, where the capitals of the columns support a roof of Chartres, running under the choir and its aisles, frequently assigned to Bishop Fulbert in 1029, but more probably coeval with the superstructure; and of Bourges, where the crypt is in the Pointed style, extending beneath the choir. The church of the Holy Trinity attached to Queen Matilda's foundation—the "Abbaye aux Dames" at Caen—has a Norman crypt where the thirty-four pillars are as closely set as those at Worcester. The church of St Etutropius at Saintes also has a crypt of the 11th century, of very large dimensions, which deserves special notice; the capitals of the columns exhibit very curious carvings. Earlier than any already mentioned is that of St Gervase of Rouen, considered by E. A. Freeman "the oldest ecclesiastical work to be seen north of the Alps." It is apsidal, and in its walls are layers of Roman brick. It is said to contain the remains of two of the earliest apostles of Gaul—St Mello and St Avitain. There are numerous crypts in Germany. One at Göttingen may be mentioned, where cylindrical shafts and capitals of singular design support vaulting of great elegance and lightness. "Fergus the Norman" also has a vaulted crypt beneath the city hall.

The crypts of the cathedrals or churches at Halberstadt, Hildesheim and Naumburg also deserve to be noticed; that of Lübeck may be rather called a lower choir. It is 20 ft. high and vaulted.

The Italian crypts, when found, as a rule reproduce the "confesso" of the primitive churches. That beneath the chancel of St Michele at Pavia is an excellent typical example, probably dating from the 10th century. It is apsidal and vaulted, and is seven bays in length. That at S. Zeno at Verona (c. 1138) is still more remarkable; its vaulted roof is upborne by forty columns, with curiously carved capitals. It is approached from the west by a double flight of steps and contains many ancient monuments. S. Mininato at Florence, begun in 1013, has a very spacious crypt at the east end, forming virtually a second choir. It is seven bays in length and vaulted. The most remarkable crypt in Italy, however, is perhaps that of St Mark's, Venice. The plan of this is almost a Greek cross. Four rows of nine columns each run from end to end, and two rows of three each occupy the arms of the cross, supporting long stunted arches on which rests the pavement of the church above. This also constitutes a lower church, containing a choros cantorum formed by a low stone screen, not unlike that of S. Clemente at Rome (see BASILICA), enclosing a massive stone altar with four low columns. This crypt is reasonably supposed to belong to the church founded by the pope P. Orseolo in 977. There are also crypts deserving notice at the cathedrals of Brescia, Fiesole and Modena, and the churches of S. Ambrogio and S. Eustorgio at Milan. The former was unfortunately modernized by St Charles Borromeo. The crypt at Assisi is really a second church at a lower level, and being built on the steep side of a hill is well lighted. The whole fabric is a beautiful specimen of Italian Gothic, and both the lower and upper churches are covered with rich frescoes.

Domestic crypts are of frequent occurrence. Medieval houses had as a rule their chief rooms raised above the level of the ground upon vaulted substructures, which were used as cellars and storerooms. These were sometimes partially underground, sometimes entirely above it. The underground vaults often remain when all the superstructure has been swept away, and from their Gothic character are frequently mistaken for ecclesiastical buildings. The older English towns are full of crypts of this character, now used as cellars. They occur in Oxford and Rochester, are very abundant in the older parts of Bristol, and, according to J. H. Parker, "nearby the whole city of Chester is built upon a series of them with the Rows or passages made on the top of the vaults" (Domestic Architecture, iii. 91). The crypt of Gerard's Hall in London, destroyed in the construction of New Cannon Street, figured by Parker (Dom. Arch. ii. 185), was a beautiful example of the lower storey of the residence of a wealthy merchant of the time of Edward I. It was divided down the middle by a row of four slender cylindrical columns supporting a very graceful vault. The finest example of a similar crypt remaining in England is that beneath the Guildhall of London. The date of this is early in the 15th century—1411. It is a large and lofty apartment, divided into four alleys by two rows of clustered shafts supporting a rich lierne vault with ribs of considerable intricacy. There is a fine vaulted crypt of the same date and of similar character beneath St Mary's Hall, the Guildhall of the city of Coventry. (E. V.)

CRYPTEIA (Gr. κρύπτεια, to hide), a kind of secret police in ancient Sparta, founded, according to Aristotle, by Lycurgus; there is, however, no real evidence as to the date of its origin. The institution was under the supervision of the ephors, who, on entering office, annually proclaimed war against the helots (serf-class) and thus absolved from the guilt of murder any Spartan who should slay a helot. It was instituted primarily as a precaution against the ever-present danger of a helot revolt, and secondarily perhaps as a training for young Spartans, who were sent out by the ephors to keep watch on the helots and assassinate any who might appear dangerous. Plato ( Laws, i. p. 633) emphasizes the former aspect, but there can be little doubt that all events after the revolt of 494 (see Cypres), and its more sinister purpose was predominant, as we may gather from the secret massacre of 2000 helots who, on the invitation of the ephors, claimed to have rendered distinguished service (Thuc. iv. 80).

CRYPTOBANCUS, a genus of thoroughly aquatic, but lung-breathing tailed Batrachia, of the family Amphiumidae, characterized by a heavy, flattened build, a very porous tuberous skin, with a frilled fold along each side, short stout limbs with four very short fingers and five very short toes, and minute eyes without lids. The vertebræ are biconcave, and although the gills are lost in the adult, ossified gill-arches, two to four in number, persist. A strong series of vomerine teeth extends across the palate. Three species of this genus are known. One is the well-known fossil of Oenigena first described as Homo duumel seclusa and shown by Cuvier to be nearly related to the gigantic salamander of Japan, Cryptobranchus maximus, which has since been found to inhabit China also; the third is the hellbender, mud-puppy or water-dog of North America, C. allegheniensis, also known under the name of Menopoma. Both the fossil C. schwechaei and C. maximus grow to a length of over 5 ft. and are by far the largest Urodeles known, whilst C. allegheniensis reaches the respectable length of 18 in.

The eggs are laid in roseary-like strings. They have been found, in Japan, deposited in deep holes in the water, where they form large clumps (70 to 80 eggs) round which the female coils herself. The gigantic salamander has also bred in the Amsterdam zoological gardens, the eggs numbering upwards of 500; the male, it is stated, took charge of the eggs, and for the
ten weeks which elapsed before the release of the last larva, he kept close to them, at times crawling among the coiled mass of egg-strings or lifting them up, evidently for the purpose of aeration. The larva on leaving the egg is about an inch long, provided with three branched external gills on each side, and showing mere rudiments of the four limbs.

**CRYPTOGRAPHY** (from Gr. κρύψτος, hidden, and γράφειν, to write), or writing in cipher, called also steganography (from Gr. στεγάω, a covering), the art of writing in such a way as to be incomprehensible except to those who possess the key to the system employed. The unravelling of the writing is called deciphering. Cryptography having become a distinct art, Bacon (Lord Verulam) classed it (under the name *ciphers*) as a part of grammar. Secret modes of communication have been in use from the earliest times. The Lacedemonians had a method called the *scytale*, from the staff *(σκυταλή)* employed in constructing and deciphering the message. When the Spartan ephors wished to forward their orders to their commanders abroad, they would slantwise a narrow strip of parchment upon the *σκυτάλη* so that the edges met close together, and the message was then added in such a way that the centre of the line of writing was on the edges of the parchment. When unwound the scroll consisted of broken letters; and in that condition it was impossible to decipher; but when resolved into the cipher the method by which it came deciphering it by means of a *σκυτάλη* exactly corresponding to that used by the ephors. Polybius has enumerated other methods of cryptography.

The art was in use also amongst the Romans. Upon the revival of letters methods of secret correspondence were introduced into private business, diplomacy, plots, &c.; and as the study of this art has always presented attractions to the ingenuous, a curious body of literature has been the result.

John Trithemius (d. 1516), the abbot of Spanheim, was the first important writer on cryptography. His *Polygraphia*, published in 1518, has passed through many editions, and has supplied the basis upon which subsequent writers have worked. It was begun at the desire of the duke of Bavaria; but Trithemius did not at first intend to publish it, on the ground that it would be injurious to public interests. A *Steganographia* published at Lyons (? 1531) and later at Frankfort (1600), is also attributed to him. The next treaties of importance were those of Giovanni Battista della Porta, the Neapolitan mathematician, who wrote De fictatis literarum notis, 1563; and of Blaise de Vigenère, who published *Traité de l'art de penser secrètement* in 1588. Bacon proposed an ingenious system of cryptography on the plan of what is called the double cipher; but while lending to the art the influence of his great name, he gave an intimation as to the general opinion formed of it and as to the classes of men who used it. For when prosecuting the Earl of Somerset in the matter of the poisoning of Overbury, he urged it as an aggravation of the crime that the Earl and Overbury "had cyphers and jargons for the king and queen and all the great men,—things seldom used but either by princes and their ambassadors and ministers, or by such work or practise against or, at least, upon princes."

Other eminent Englishmen were afterwards connected with the art. John Wilkins, subsequently bishop of Chester, published in 1641 an anonymous treatise entitled *Mercury, or The Secret and Swift Messenger*,—a small but comprehensive work on the subject, and a timely gift to the diplomats and leaders of the Civil War. The deciphering of many of the royalist papers of that period, such as the letters that fell into the hands of the parliament at the battle of Naseby, has by Henry Stubbe been charged on the celebrated mathematician Dr. Wallis.

Dr Wallis elsewhere states that this art, formerly scarcely known to any but the secretaries of princes, &c., had grown very common and familiar during the civil commotions, "so that now there is scarce a person of quality but is more or less acquainted with it, and doth, as there is occasion, make use of it."

Subsequent writers on the subject are John Falconer (*Cryptomnesia patefacta*, 1685); John Davys (*An Essay on the Art of Deciphering: in which is inserted a Discourse of Dr Wallis*, 1737); Philip Thicknesse (*A Treatise on the Art of Deciphering and of Writing in Cipher*, 1772); William Blair (the writer of the comprehensive article "Cipher" in *Rees's Cyclopædia*, 1819); and G. von Marten (*Cours diplomatique*, 1801 (a fourth edition of which appeared in 1851). Perhaps the best modern work on this subject is the *Kryptographik* of J. L. Klüber (*Tübingen*, 1809), who was drawn into the investigation by inclination and official circumstances. In this work the different methods of cryptography are classified. Amongst others of lesser merit who have treated of this art may be named Gustavus Selenus (*i.e.* Augustus, duke of Brunswick, 1624); Cospi, translated by Nicerin in 1641; the marquis of Worcester, 1659; Kircher, 1663; Schott, 1665; Ludwig Heinrichiller, 1682; Comiers, 1690; Baring, 1737; Conrad, 1739, &c. See also a paper on *Elizabethan Cipher-books* by A. J. Butler in the Bibliographical Society's *Transactions*, London, 1901.

Schemes of cryptography are endless in their variety. Bacon lays down the following as the "virtues" to be looked for in them: "that they be not laborious to write and read; that they be impossible to decipher; and, in some cases, that they be without suspicion." Thus, cryptography was regarded by all the modes that have been advanced, including that of Bacon himself, which has been unduly extolled by his admirers as "one of the most ingenious methods of writing in cipher, and the most difficult to be deciphered, of any yet contrived" (*Thicknesse*, p. 13).

The simplest and commonest of all the ciphers is that in which the writer selects in place of the proper letters certain other letters in regular advance. This method of transposition was used by Julius Caesar. He, "per quartam elementorum literam," wrote *d* for *a*, *e* for *b*, and so on. There are instances of this arrangement in the Jewish rabbis, and even in the sacred writers. An illustration of it occurs in Jeremiah (xxv. 26), where the prophet, to conceal the meaning of his prediction from all but the initiated, writes *Sheshak* instead of *Babel* (*Babylon*), the place meant; i.e. in place of using the second and twelfth letters of the Hebrew alphabet (*b*, *l*) from the beginning, he wrote the second and twelfth (*sh*, *h*) from the end. To this kind of cipher-writing Buxtorf gives the name *Athbash* (from a *a* the first letter of the Hebrew alphabet, and *th* the last; *b* the second from the beginning and *h* from the end). Another Jewish cabbalist of like nature was called *Albam*; of which an example is in Isaiah vii. 6, where Tabeal is written for Remalah. In its adaptation to English this method of transposition, of which there are many modifications, is comparatively easy to decipher.

A rough key may be derived from an examination of the respective quantities of letters in a type-founder's bill, or a printer's "case." The decipherer's first business is to classify the letters of the secret message in the order of their frequency. The letter that occurs oftener is *e*; and the next in order of frequency is *t*. The following groups come after these, separated from each other by degrees of decreasing frequency:—*a*, *o*, *n*, *i*; *r*, *s*, *h*, *k*, *d*, *l*, *c*, *w*, *u*, *m*; *f*, *y*, *g*, *p*, *b*, *v*, *k*, *x*, *g*, *j*, *s*. All the single letters must be *a*, *i* or *O*. Letters occurring together are *ee*, *oo*, *ff*, *ll*, *ss*, &c.

The commonest words of two letters are (roughly arranged in the order of their frequency) *to*, *in*, *it*, *is*, *be*, *he*, *by*, or, *as*, *at*, *an*, *so*, &c. The commonest words of three letters are *the* and (in great excess), *for*, *are*, *but*, *all*, *not*, &c.; and of four letters—*that*, *with*, *from*, *have*, *this*, *they*, &c. Familiarity with the composition of the language will suggest numerous other words, some that are rarely used (the cipher end). He may obtain other hints from Poe's tale called *The Gold Bug*. As to messages in the continental languages constructed upon this system of transposition, rules for deciphering may be derived from Breithaupt's *Ars decifrorum* (1737), and other treatises.

Bacon remarks that though ciphers were commonly in letters and alphabets yet they might be in words. Upon this basis codes have been constructed, classified words taken from dictionaries being made to represent complete ideas. In recent
years such codes have been adapted by merchants and others to communications by telegraph, and have served the purpose not only of keeping business affairs private, but also of reducing the excessive cost of telegraphic messages to distant markets. Obviously this class of ciphers presents greater difficulties to the skill of the decipherer.

Figures and other characters have also been used as letters; and with them ranges of numerals have been combined as the representatives of syllables, parts of words, words themselves, and complete phrases. Under this head must be placed the despatches of Giovanni Michael, the Venetian ambassador to England in the reign of Queen Mary, documents which have only of late years been deciphered. Many of the private letters and papers from the pen of Charles I. and his queen, who were adepts in the use of ciphers, are of the same description. One of that monarch's letters, a document of considerable interest, consisting entirely of numerals purposely complicated, was in 1858 deciphered by Professor Wheatstone, the inventor of the ingenious crypto-machine, and printed by the Philobiblon Society. Other letters of the like character have been published in the First Report of the Royal Commission on Historical Manuscripts (1870). In the second and subsequent reports of the same commission several keys to ciphers have been catalogued, which seem to refer themselves to the methods of cryptography under notice. In this connection may also be mentioned the "character," which the diarist Pepys drew up when clerk to Sir George Downing and secretary to the earl of Sandwich and to the admiralty, and which are frequently mentioned in his journal. Pepys describes one of them as "a large character," over which he spent much time, but which was at length finished, 25th April 1660; "it being," says he, "very handsomely done and a very good one in itself, but that not truly alphabetical."

Shorthand marks and other arbitrary characters have also been largely imported into cryptographic systems to represent both letters and words, but more commonly the latter. This plan is said to have been first put into use by the old Roman poet Ennius. It formed the basis of the method of Cicero's freedman, Tiro, who seems to have systematized the labours of his predecessors. A large quantity of these characters have been engraved in Gruter's Inscriptiones. The correspondence of Charlemagne was in part made up of marks of this nature. In Rees's Cyclopaedia specimens were engraved of the cipher used by Cardinal Wolsey at the court of Vienna in 1524, of that used by Sir Thomas Smith at Paris in 1503, and of that of Sir Edward Stafford in 1586; in all of which arbitrary marks are introduced. The first English system of shorthand of which Characteritic, a system of cancellons, was made to the same category of ciphers. Their favourite system of Charles I., used by him during the year 1646, was one made up of an alphabet of twenty-four letters, which were represented by four simple strokes varied in length, slope and position. This alphabet is engraved in Clive's Linear System of Shorthand (1830), having been found amongst the royal manuscripts in the British Museum. An interest attaches to this cipher from the fact that it was employed in the well-known letter addressed by the king to the earl of Glamorgan, in which the former made concessions to the Roman Catholics of Ireland.

Complications have been introduced into ciphers by the employment of "dummy" letters,—"nulls and insignificant," as Bacon terms them. Other devices have been introduced to perplex the decipherer, such as spelling words backwards, making false divisions between words, &c. The greatest security against the decipherer has been found in the use of elaborate tables of letters, arranged in the form of the multiplication table, the message being constructed by the aid of preconcerted key-words. Details of the working of these ciphers may be found in the treatises named in this article. The deciphering of them is one of the most difficult tasks. A method of this kind is explained in the cryptoporticus of Dr. John Barwick, whose correspondence with Hyde, afterwards earl of Clarendon, was carried on in cryptography. In a letter dated 20th February 1659/60, Hyde, alluding to the skill of his political opponents in deciphering, says that "no body needs to fear them, if they write carefully in good ciphers." In his next he allays his correspondent's apprehensions as to the deciphering of their letters: "I confess to you, as I am sure no copy could be gotten of any of my ciphers from hence, so I did not think it probable that they could be got on your side the water. But I was as confident, till you tell me you believe it, that the devil himself cannot decipher a letter that is well written, or find that 100 stands for Sir H. Vane. Let me know if there be many of these things, wrote, deciphered; and I very well remember that in the volume they published there was much left in cipher which could not be understood, and which I believe they would have explained if it had been in their power."

An excellent modification of the key-word principle was constructed by Admiral Sir Francis Beaufort. Ciphers have been constructed on the principle of altering the places of the letters without changing their powers. The message is first written Chinese-wise, upward and downward, and the letters are then combined in given rows from left to right. In the celebrated cipher used by the earl of Argyll when plotting against James II., he altered the positions of the words. Sentences of an indifferent nature were constructed, but the real meaning of the message was to be gathered from words placed at certain intervals. This method, which is connected with the name of Cardan, is sometimes called the trellis or cardboard cipher.

The wheel-cipher, which is an Italian invention, the string-cipher, the circle-cipher and many others are fully explained, with the necessary diagrams, in the authorities named above—more particularly by Klüber in his Kryptographik. (J. E. B.)

CRYPTOMERIA, or JAPANESE CEDAR, a genus of conifers, containing a single species, C. japonica, native of China and Japan, which was introduced into Great Britain by the Royal Horticultural Society in 1844. It is described as one of the finest trees in Japan, reaching a height of 100 or more feet, usually divided of branches along the lower part of the trunk and crowned with a conical head. The narrow, pointed leaves are spirally arranged and persist for four or five years; the cones are small, globose and borne at the ends of the branchlets, the scales are thickened at the extremity and divided into sharply pointed lobes, three to five seeds are borne on each scale. Cryptomeria is extensively used in Japan for reforesting denuded lands, as it is a valuable timber tree; it is also planted to form avenues along the public roads. In Veitch's Manual of Coniferæ (ed. 2, 1900, p. 269) reference is made to "an avenue of Cryptomeria japonica in the hills of Hakone, Japan, the trees are more than 100 ft. high, with perfectly straight trunks crowned with conical heads of foliage." Professor C. S. Sargent, in his Forest Flora of Japan, says, "Japan owes much of the beauty of its groves and gardens to the Cryptomeria. Nowhere is there a more solemn and impressive group of trees than that which surrounds the temples and tombs at Nikko where they rise to a height of 100 to 125 ft.; it is a stately tree with no rival except in the sequoias of California." Many curious varieties have been obtained by Japanese horticulturists, including some dwarf shrubby forms not exceeding a few feet in height. When grown in Great Britain Cryptomeria requires a deep, well-drained soil with plenty of moisture, and protection from cold winds.

CRYPTO-PORTICUS (Gr. κρυπτός, concealed, and Lat. porticus), an architectural term for a concealed or covered passage, generally underground, though lighted and ventilated from the open air. One of the best-known examples is the crypto-porticus under the palaces of the Caesars in Rome. In Hadrian's villa in Rome they formed the principal private intercommunication between the several buildings.

CRYSTAL-GAZING, or SCRIVING, the term commonly applied to the induction of visual hallucinations by concentrating the gaze on any clear deep, such as a crystal or a ball of polished rock crystal. Some persons do not even find a clear deep necessary, and are content to gaze at the palm of the hand, for example, when hallucinatory pictures, as they declare, emerge.
CRYSTAL-GAZING

Among objects used are a pool of ink in the hand (Egypt), the liver of an animal (tribes of the North-West Indian frontier), a horn filled with water (Polynesia), quartz crystals (the Apaches and the Kaukai tribe of New South Wales), a smooth slice of polished black stone (the Huille-cho of South America), water in a vessel (Zulus and Siberians), a crystal (the Incas), a mirror (classical Greece and the middle ages), the finger-nail, a swordblade, a ring-stone, a glass of sherry, in fact almost anything. Much depends on what the “seer” is accustomed to use, and some persons who can “scry” in a glass ball or a glass water-bottle cannot “scry” in ink.

The practice of inducing pictorial hallucinations by such methods as these has been traced among the natives of North and South America, Asia, Australia, Africa, among the Maoris, who sometimes use a drop of blood, and in Polynesia, and is thus practically of world-wide diffusion. This fact was not observed (that is, the collections of examples were not made) till recently, when experiments in private non-spiritualist circles drew attention to crystal-gazing, a practice always popular among peasants, and known historically to have survived through classical and medieval times, and, as in the famous case of Dr. Dee, after the Reformation.

The early church condemned speculatii (mirror-gazers), and Aubrey and the Memoirs of Saint-Simon contain “scrying” anecdotes of the 17th and 18th centuries, while Sir Walter Scott’s story, My Aunt Margaret’s Mirror, is based on a tradition of a 17th century Scottish family. The practice, in all times and countries, was used for purposes of divination. The seer detected unknown criminals, or described remote events, or even professed to foretell things future. Sometimes the supposed magician or medicine man himself did the scrying; occasionally he enabled his client to see for himself; often a child was selected as the scryer. The process was usually explained as the result of the action of a spirit, angel or devil, and many unessential formulae, invocations, “calls,” written charms with cabalistic signs, and fumigations, were employed. These things may have had some effect by way of suggestion; the scryer may have been brought by them into an appropriate frame of mind; but, as a whole, they are tedious and superfluous.

A person can either induce the pictorial hallucinations (he may discover his capacity by accident, like George Sand, as she tells in her Memoirs—and other cases are known), or he cannot induce them, though he stare till his eyes water. It is almost universally found, in cases of successful experiment, that the glass ball, for example, takes a milky or misty aspect, that it then grows black, reflections disappearing, and that then the pictures emerge. Some people arrive at seeing the glass ball milky or misty, and can go no further. Others see pictures of persons or landscapes, only in black and white, and motionless. Others see in the glass coloured figures of men, women, and animals in motion; while in rarer cases the ball disappears from view, and the scryer finds himself apparently looking at an actual scene. In a few attested cases two persons have shared the same vision. In experiments with magnifying glasses, and through spars, the ordinary effects of magnifying and of alteration of view are sometimes produced; sometimes they are not. The evidence, of course, is necessarily only that of the scryers themselves, but repeated experiments by persons of probity, and unfamiliar with the topic, combined with the world-wide existence of the practice, prove that hallucinatory pictures are really induced.

It has not been found possible to determine, before experiment, whether any given man or woman will prove capable of the hallucinatory experiences. Many subjects with strong powers of “visualization,” or seeing things “in the mind’s eye,” cannot scry; others are successful in various degrees. We might expect persons who have experienced spontaneous visual hallucinations, of the kind vulgarly styled “ghosts” or “wraiths,” to succeed in inducing pictures in a glass ball. As a matter of fact such persons sometimes can and sometimes cannot see pictures in the way of crystal-gazing; while many who can see in the crystal have had no spontaneous hallucinations. It is useless to make experiments with hysterical and visionary people, “whose word no man relies on”; they may have the hallucinatory experiences, but they would say that they had in any case.

The nearest analogy to crystal visions, as described, is the common experience of “hypnagogic illusions” (cf. Alfred Maury. Les Rêves et le sommeil). With remedied hypnotic sleep and waking, many people see faces, landscapes and other things flash upon their view, pictures often brilliant, but of very brief duration and rapid mutation. Sometimes the subject opens his eyes to get rid of an unpleasant vision of this kind. People who cannot scry may have these hypnagogic illusions, and, so far, may partly understand the experience of the scryer who is wide awake. But the visions of the scryer often endure for a considerable time. He or she may put the glass down and converse, and may find the picture still there when the ball is taken up again. New figures may join the figure first seen, as when one enters a room. In these respects, and in the awakened of the scryer, crystal pictures differ from hypnagogic illusions.

In other ways the experiences coincide, the pictures are either fanciful, like illustrations of some unread history or romance, or are revivals of remembered places and faces.

Occasionally, in hypnagogic illusions, the observer can see the picture develop rapidly out of a blot of light or colour, beheld by the closed eyes. One or two scryers think that they, too, can trace the picture as it develops on the suggestion of some passage of light, colour or shadow in the glass or crystal. But, as a rule, the scryer cannot detect any process of development from such points de mire; though this may be the actual process.

On the whole there seems little doubt that successful crystalgazing is the exertion of a not uncommon though far from universal faculty, like those of “chromatic auditions”—the vivid association of certain sounds with certain colours—and the mental seeing of figures arranged in coloured diagrams (Galan, Inquiry into Human Faculty, pp. 114-154). The experience of hypnagogic illusions also seems far more rare than ordinary dreaming in sleep. Unfortunately, while these phenomena have been carefully studied by officially scientific characters, in England orthodox savants have disdained to observe crystal-gazing, while in France psychologists have too commonly experimented with subjects professionally hysterical and quite untrustworthy. Our remarks are therefore based mainly on considerable personal study of “scrying” among normal British subjects of both sexes, to whom the topic was previously unknown.

The superstitious associations of crystal-gazing, as of hypnotism, appear to bar the way to official scientific investigation, and the fluctuating proficiency of the seers, who cannot command success, or determine the causes and conditions of success and failure, tends in the same direction. The existence, too, of paid professionals who lead astray silly women, encourages the natural scientific contempt for the study of the faculty.

The seeing of the pictures, as far as we have spoken of it, appears to be a thing unusual, but in no way abnormal, any more than dreams or hypnagogic illusions are abnormal. Crystal pictures, however, are commonly dismissed as mere results of “imagination,” a theory which, of course, is of no real assistance to psychology. Persons of recognized “imaginativeness,” such as novelists and artists, do not seem more or less capable of the hallucinatory experiences than their sober neighbours; while persons not otherwise recognizably “imaginative” (we could quote a singularly accurate historian) are capable of the experiences. It is unfortunate, as it awakens prejudice, but in the present writer’s opinion it is true, that crystal-gazing sometimes is rewarded with results which may be styled “supra-normal.” In addition to the presentation of revived memories, and of “objectivation of ideas or images consciously or unconsciously in the mind of the percipient,” there occur “visions, possibly telepathic or clairvoyant, implying acquisition of knowledge by supra-normal means.”

A number of examples occurring during experiments made by the present writer and by his acquaintances in 1867 were carefully recorded and attested by the signatures of all concerned.

1 Proceedings of the Society for Psychical Research, v. 486.
CRYSTALLITE

The cases, or rather a selection of the cases, are printed in A. Lang's book, The Making of Religion (2nd ed., London, 1902, pp. 87-101). Others are chronicled in A. Lang's Introduction to Mr. N. W. Thomas's work, Crystal Gazing (1905). The experiments took this form: any person might ask the scryer (a lady who had never previously heard of crystal-gazing) "to see what he was thinking of." The scryer, who was a stranger in a place which she had never visited before, gave, in a long series of cases, a description of the person or place on which the inquirer's thoughts were fixed. The descriptions, though three or four entire failures occurred, were of remarkable accuracy as a rule, and contained facts and incidents unknown to the inquirers, but confirmed as accurate. In fact, some Oriental scenes and descriptions of incidents were corroborated by a letter from India which arrived just after the experiment; and the same thing happened when the events described were occurring in places less remote. On one occasion a curious set of incidents were described, which happened to be vividly present to the mind of a sceptical stranger who chanced to be in the room during the experiment; events unknown to the inquirer in this instance. As an example of the minuteness of description, an inquirer, thinking of a brother in India, an officer in the army, whose hair had suffered in an encounter with a tiger, had described to her an officer in undress uniform, with bald scars through the hair on his temples, such as real cases of crystal-gazing, many cases of such coincidences were too high to admit of explanation by chance coincidence, but success was not invariable. On one occasion the scryer could see nothing, "the crystal preserved its natural diaphaneity," as Dr Dee says; and there were failures with two or three inquirers. On the other hand no record was kept in several cases of success.

Whoever can believe that the successes were numerous and that descriptions were given correctly—not only of facts present to the mind of inquirers, and of other persons present who were not consciously taking a share in the experiments, but of facts necessarily unknown to all concerned—must of course be most impressed by the latter kind of success. If the process commonly styled "telepathy" exists (see TELEPATHY), that may account for the scryer's power of seeing facts which are in the mind of the inquirer. But when the scryers see details of various sorts, which are unknown to the inquirer, but are verified on inquiry, then telepathy perhaps fails to provide an explanation. We seem to be confronted with actual clairvoyance (q.v.), or vue à distance. It would be vain to form hypotheses as to the operations or faculties by which the scryers gained success. This way lie metaphysics, with Hegel's theory of the Sensitive Soul, or Myers' theory of the Subliminal Self. "The intuitive soul," says Hegel, "oversteps the conditions of time and space; it beholds things remote, things long past, and things to come."

What we need, if any progress is to be made in knowledge of the subject, is not a metaphysical hypothesis, but a large, carefully tested, and well-recorded collection of examples, made by savants of recognized standing. At present we are where we were in electrical science, when Newton produced curious sparks while rubbing glass with paper. By way of facts, we have only a large body of unattested anecdotes of supra-normal successes in crystal-gazing, in many lands and ages; and the scanty records of modern amateur investigators, like the present writer. Even from these, if the honesty of all concerned be granted (and even clever dishonesty could not have produced many of the results), it would appear that we are investigating a strange and important human faculty. The writer is acquainted with no experiments in which it was attempted to discern the future (except in trivial cases as to events on the turf, when chance coincidence might explain the successes), and only with two or three cases in which there was an attempt to help historical science and discern the past by aid of psychic methods. The results were interesting and difficult to explain, but the experiments were few. Ordinary scryers of fancy pictures are common enough, but scryers capable of apparently supra-normal successes are apparently rare. Perhaps something depends on the inquirer as well as the scryer.

The method of scrying, as generally practised, is simple. It is usual to place a glass ball on a dark ground, to sit with the back to the light, to focus the gaze on the ball (disregarding reflections, if these cannot be excluded), and to await results. Perhaps from five to ten minutes is a long enough time for the experiment. The scryer may let his consciousness play freely, but should not be disturbed by lookers-on. As a rule, if a person has the faculty he "sees" at the first attempt; if he fails in the first three or four efforts he need not persevere. Solitude is advisable at first, but few people can find time amounting to ten minutes for solitary studies of this sort, so busy and so gregarious is mankind. The writer has no experience of trance, sleep or auto-hypnotization produced in such experiments; scryers have always seemed to retain their full normal consciousness. As regards scepticism concerning the faculty we may quote what Mr Galton says about the faculty of visualization: "Scientific men as a class have feeble power of visual reproduction. . . . They had a mental deficiency of which they were unconscious, and, enough natural, supposed that those who affirmed they were possessed of it were romancing."

AUTHORITIES.—A useful essay is that of "Miss X" (Miss Goodrich Freez) in the Proceedings of the Society for Psychical Research, v. ed., 1892. Dr. J. H. Smythies's account of experiments of the author's own experiments are recorded. A. Lang's The Making of Religion, ch. v., contains anthropological examples and a series of instances. In N. W. Thomas's Crystal Gazing the history of the psychology of crystal-gazing and clairvoyance is set out in instances. For Egypt, see Lane's Modern Egyptians, and the Journal of Sir Walter Scott, xi. 419-421, with Quarterly Review, No. 117, pp. 196-208. These Egyptian experiments of 1830 were vitiated by the methods, the writer, Mr. Thomas, a scryer, was a given person, named. He ought not, of course, to be told more than that he is to desire the inquirer's thoughts, and there ought never to be physical contact, as in holding hands, between the inquirer and the scryer during the experiment. There is a chapter on crystal-gazing in Les Magoies et les tses Exes of Dr. Janet (1858). His statements are sometimes demonstrably inaccurate (see Making of Religion, Appendix C). A curious passage on the subject, by Ibn Khaldun, an Arabian medieval savant, is quoted by Mr. Thomas from the printed Editions of MSS. in the Bibliothèque Nationale. There is also a chapter on crystal-gazing in Myers' Human Personality. (A. L.)

CRYSTALLITE. In media which, on account of their viscosity, offer considerable resistance to those molecular movements which are necessary for the building and growth of crystals, rudimentary or imperfect forms of crystallization very frequently occur. It is only when they are rapidly cooled, producing various kinds of pitchstone, obsidian, &c. When examined under the microscope these rocks consist largely of a perfectly amorphous or glassy base, through which are scattered great numbers of very minute crystals (microliths), and other bodies, termed crystallites, which seem to be stages in the formation of crystals. Crystallites may also be produced by allowing a solution of sulphur in carbon disulphide mixed with Canada balsam to evaporate slowly, and their development may be watched on a microscopic slide. Small globules appear (globulites), spherical and non-crystalline (so far as can be ascertained). They may coalesce or may arrange themselves into rows like strings of beads—margarites—(Gr. μαργαρίτης, a pearl) or into groups with a somewhat radiant arrangement—globospheres. Occasionally they take elongated shapes—longulites and faculites (Lat. baculus, a staff). The largest may become crystalline, changing suddenly into polyhedral bodies with evident double refraction and the optical properties belonging to crystals. Others become long and thread-like—trichites (Gr. τρίχη, τριχός, hair)—and these are often curved, and a group of them may be implanted on the surface of a small crystal. All these forms are found in vitreous igneous rocks. H. P. J. Vogelsang, who was the first to direct much attention to them, believes that the globulites are preliminary stages in the formation of crystals. Microliths, as distinguished from crystallites, have crystalline properties, and evidently belong to definite minerals or salts. When sufficiently large they are often recognizable, but usually
they are so small, so opaque, or so densely crowded together that this is impossible. In igneous rocks they are usually felspar, augite, enstatite, and iron oxides, and are found in abundance only where there is much uncrystallized glassy base; in contact-altered sediments, slags, &c., microlithic forms of garnet, spinel, sillsanite, cordierite, various lime silicates, and many other substances have been observed. Their form varies greatly, e.g. thin fibres (sillsanite, augite), short prisms or rods (felspar, enstatite, cordierite), or equidimensional grains (augite, spinel, magnetite). Occasionally they are perfectly shaped though minute crystals; more frequently they appear rounded (magnetite, &c.), or have brush-like terminations (augite, felspar, &c.). The larger microliths may contain enclosures of glass, and it is very common to find that the prisms have hollow, funnel-shaped ends, which are filled with vitreous material. These microliths, under the influence of crystalline forces, may rank themselves side by side to make up skeleton crystals and networks, or feathery and arborescent forms, which are more or less closely the laws of crystallization of the substance to which they belong. They bear a very close resemblance to the arborescent frost flowers seen on window panes in winter, and to the stellate snow crystals. In magnetite the growths follow three axes at right angles to one another; in augite this is nearly, though not exactly, the case; in hornblende and augite it may frequently be observed; corresponding to the prism angle of the fully-determined crystal. The interstices of the network may be partly filled up by a later growth. In other cases the crystalline arrangement of the microliths is less perfect, and branching, arborescent or feathery groupings are produced (e.g. felspar, augite, hornblende). Spherulites may be regarded as radiate aggregates of such microliths (mostly felspar mixed with quartz or tridymite). If larger porphyritic crystals occur in the rock, the microliths of the vitreous base frequently grow outwards from their faces; in some cases a definite parallelism exists between the two, but more frequently the early crystal has served merely as a centre, or nucleus, from which the microliths and spherulites have spread in all directions. (J. S. F.)

**CRYSTALLIZATION.** The art of obtaining a substance in the form of crystals; it is an important process in chemistry since it permits the purification of a substance, or the separation of the constituents of a mixture. Generally a substance is more soluble in a solvent at a higher temperature, and consequently, if a solution is concentrated, the solute will separate in virtue of the diminished solubility, and the slower the cooling the larger and more perfect will be the crystals formed. If, as sometimes appears, a solution refuses to crystallize, the expedient of inoculating the solution with a minute crystal of the same substance, or with a similar substance, may be adopted; shaking the solution, or the addition of a drop of another solvent, may also occasion the desired result. "Fractional crystallization" consists in repeatedly crystallizing a salt so as to separate the substances of different solubilities. Examples are especially presented in the study of the rare-earths. Other conditions under which crystals are formed are given in the article **CRYSTALLOGRAPHY**.

**CRYSTALLOGRAPHY** (from the Gr. κρύσταλλον, ice, and γράφει, to write), the science of the forms, properties and structure of crystals. Homogeneous solid matter, the physical and chemical properties of which are the same about every point, may be either amorphous or crystalline. In amorphous matter all the properties are the same in every direction in the mass; but in crystalline matter certain of the physical properties vary with the direction. The essential properties of crystalline matter are of two kinds, viz. the general properties, such as density, specific heat, melting-point and chemical composition, which do not vary with the direction; and the directional properties, such as cohesion and elasticity, various optical, thermal and electrical properties, as well as external form. By reason of the homogeneity of crystalline matter the directional properties are the same in all parallel directions in the mass, and there may be a certain symmetrical repetition of the directions along which the properties are the same.

When the crystallization of matter takes place under conditions free from outside influences the peculiarities of internal structure are expressed in the external form of the mass, and there results a solid body bounded by plane surfaces intersecting in straight edges, the directions of which bear an intimate relation to the internal structure. Such a polyhedron (ῥιζής, many, ἑξά, base or face) is known as a crystal. An example of this is sugar-candy, of which a single isolated crystal may have grown freely in a solution of sugar. Matter presenting well-defined and regular crystal forms, either as a single crystal or as a group of individual crystals, is said to be crystallized. If, on the other hand, crystallization has taken place about several centres in a confined space, the development of plane surfaces may be prevented, and a crystalline aggregate of differently orientated crystal-individuals results. Examples of this are afforded by loaf sugar and statuary marble.

After a brief historical sketch, the more salient principles of the subject will be discussed under the following sections:—

I. **CRYSTALLINE FORM.**

(a) **Symmetry of Crystals.**

(b) **Simple Forms and Combinations of Forms.**

(c) **Law of Rational Indices.**

(d) **Zones.**

(e) **Projection and Drawing of Crystals.**

(f) **Crystal System and units Classes.**

1. **Cubic System.**

2. **Tetragonal System.**

3. **Orthorhombic System.**

4. **Monoclinic System.**

5. **Anorhomic System.**

6. **Hexagonal System.**

(g) **Regular Grouping of Crystals (Twinning, &c.).**

(h) **Irregularities of Growth of Crystals: Characters of Faces.**

II. **PHYSICAL PROPERTIES OF CRYSTALS.**

(a) **Elasticity and Cohesion (Cleavage, Etching, &c.).**

(b) **Optical Properties (Interference figures, Pleochroism, &c.).**

(c) **Thermal Properties.**

(d) **Magnetic and Electrical Properties.**

III. **RELATION BETWEEN CRYSTALLINE FORM AND CHEMICAL COMPOSITION.**

Most chemical elements and compounds are capable of assuming the crystalline condition. Crystallization may take place when solid matter separates from solution (e.g. sugar; salt, alum), from a fused mass (e.g. sulphur, bismuth, felspar), or from a vapour (e.g. iodine, camphor, haematite; in the last case by the interaction of ferric chloride and steam). Crystalline growth may also take place in solid amorphous matter, for example, in the devitrification of glass, and the slow change in metals when subjected to alternating stresses. Beautiful crystals of many substances may be obtained in the laboratory by one or other of these methods, but the most perfectly developed and largest crystals are those of mineral substances found in nature, where crystallization has continued during long periods of time. For this reason the physical science of crystallography has developed side by side with that of mineralogy. Really, however, there is just the same connexion between crystallography and chemistry as between crystallography and mineralogy, but only in recent years has the importance of determining the crystallographic properties of artificially prepared compounds been recognized.

**History.**—The word "crystal" is from the Gr. κρύσταλλον, meaning clear ice (Lat. *crystallum*), a name which was also applied to the clear transparent quartz ("rock-crystal") from the Alps, under the belief that it had been formed from water by intense cold. It was not until about the 17th century that the word was extended to other bodies, either those found in nature or obtained by the evaporation of a saline solution, which resembled rock-crystal in being bounded by plane surfaces, and often also in their clearness and transparency.

The first important step in the study of crystals was made by Nicolaus Steno, the famous Danish physician, afterwards bishop of Titiopolis, who in his treatise *De solido intra solidum naturaliter contento* (Florence, 1669; English translation, 1671) gave the
results of his observations on crystals of quartz. He found that although the faces of different crystals vary considerably in shape and relative size, yet the angles between similar pairs of faces are always the same. The further pointed out that the crystals must have grown in a liquid by the addition of layers of material upon the faces of a nucleus, this nucleus having the form of a regular six-sided prism terminated at each end by a six-sided pyramid. The thickness of the layers, though the same over each face, was not necessarily the same on different faces, but depended on the position of the faces with respect to the surrounding liquid; hence the faces of the crystal, though variable in shape and size, remained parallel to those of the nucleus, and the angles between them constant. Robert Hooke, in his Micrographia (London, 1665) had previously noticed the regularity of the minute quartz crystals found lining the cavities of flints, and had suggested that they were built up of spheroids. About the same time the double refraction and perfect rhombohedral cleavage of crystals of calcite or Iceland-spar were studied by Erasmus Bartholinus (Experimenta crystallici Islandici disdiastastici, Copenhagen, 1669) and Christian Hyggen (Traité de la lumière, Leiden, 1690); the latter supposed, as did Hooke, that the crystals were built up of spheroids. In 1695 Anton van Leeuwenhoek observed under the microscope that different kinds of the substances were formed by the crystallization of different salts. Andreas Libavius had indeed much earlier, in 1597, pointed out that the salts present in mineral waters could be ascertained by an examination of the shapes of the crystals left on evaporation of the water; and Domenico Guglielmini (Riflessioni filosofiche dedotto dalle figure de’ soli, Padova, 1706) asserted that the crystals of each salt had a shape of their own with the plane angles of the faces always the same.

The earliest treatise on crystallography is the Prodromus Crystallographiae of M. A. Cappeller, published at Lucerne in 1723. Crystals were mentioned in works on mineralogy and chemistry; for instance, C. Linnaeus in his Systema Naturae (1735) described some forty common forms of crystals amongst minerals. It was not, however, until the end of the 18th century that any real advances were made, and the French crystallographers Romé de l’Isle and the able Hâty are rightly considered as the founders of the science. J. B. L. de Romé de l’Isle (Essai de cristallographie, Paris, 1772; Cristallographie, ou description des formes propres à tous les corps du royaume minéral, Paris, 1783) made the first systematic study of the forms of the same natural or artificial substance are all integers in their relation to each other; and further, by measuring the angles between the faces of crystals with the goniometer (q.v.), he established the fundamental principle that these angles are always the same for the same kind of substance and are characteristic of it. Replacing by single planes or groups of planes all the similar edges or solid angles of a figure called the "primitive form" he derived other related forms. Six kinds of primitive forms were distinguished, namely, the cube, the regular octahedron, the regular tetrahedron, a rhombohedron, an octahedron with a rhombic base, and a double-sided pyramid. Only in the last three can there be any variation in the angles: for example, the primitive octahedron of alum, nitre and sugar were determined by Romé de l’Isle to have angles of 110°, 120° and 109° respectively. René Just Hâty in his Essai d’une théorie sur la structure des cristaux (Paris, 1784; see also his Traité on Mineralogy and Crystallography, 1801, 1822) supported and extended these views, but took for his principles the figures obtained by splitting crystals in their directions of easy fracture of "cleavage," which are a way the same in the same kind of substance. Thus he found that all crystals of calcite, whatever their external form (see, for example, figs. 1-6 in the article CALCITE), could be reduced by cleavage to a rhombohedron with interfacial angles of 75°. Further, by stacking together a number of small rhombohedra of uniform size he was able, as had been previously done by J. G. Gahn in 1773, to reconstruct the various forms of calcite crystals. Fig. 1 shows a scalenohedron (oxaN-groups, uneven) built up in this manner of rhombohedra; and fig. 2 a regular octahedron built up of cubic elements, such as are given by the cleavage of galena and rock-salt.

The external surfaces of such a structure, with their step-like arrangement, correspond to the plane faces of the crystal, and the bricks may be considered so small as not to be separately visible. By making the steps one, two or three bricks in width and one, two or three bricks in height the various secondary faces on the crystal are related to the primitive form or "cleavage nucleus" by a law of whole numbers, and the angles between them can be arrived at by mathematical calculation. By measuring with the goniometer the inclinations of the secondary faces to those of the primitive form Hâty found that the secondary forms are always related to the primitive form on crystals of numerous substances in the manner indicated, and that the width and the height of a step are always in a simple ratio, rarely exceeding that of 1:6. This laid the foundation of the important "law of rational indices" of the faces of crystals.

The German crystallographer C. S. Weiss (De indagando formarum crystallinarum charactere geometrico principali dissertato, Leipzig, 1809; Übersichtliche Darstellung der verschiedenen natürlichen Abkühlungen der Krystallisations-Systeme, Denkschrift der Berliner Akad. der Wissensch., 1814-1815) attacked the problem of crystalline form from a purely geometrical point of view, without reference to primitive forms or any theory of structure. The faces of crystals were considered by their intercepts on co-ordinate axes, which were drawn joining the opposite corners of certain forms; and in this way the various primitive forms of Hâty were grouped into four classes, corresponding to the four systems described below under the names cubic, tetragonal, hexagonal and orthorhombic. The same result was arrived at independently by F. Mohs, who further, in 1822, asserted the existence of two additional systems, with oblique axes. These two systems (the monoclinic and anorthic) were, however, considered by Weiss to be only hemihedral or tetartohedral modifications of the orthorhombic system, and they were not definitely established until 1835, when the optical characters of the crystals were found to be distinct.

A system of notation to express the relation of each face of a crystal to the co-ordinate axes of reference was devised by Weiss, and other notations were proposed by F. Mohs, A. Lévy (1825), C. F. Naumann (1826), and W. H. Miller (Treatise on Crystallography, Cambridge, 1839). For simplicity and utility in calculation the Millerian notation, which was first suggested by W. Whewell in 1825, surpasses all others and is now generally adopted, though those of Lévy and Naumann are still in use.

Although the peculiar optical properties of Iceland-spar had been much studied ever since 1669, it was not until much later that any connexion was traced between the optical characters of crystals and their external form. In 1818 Sir David Brewster found that crystals could be divided optically into three classes, viz. isotropic, uniaxial and biaxial, and that these classes corresponded with Weiss’s four systems (crystals belonging to the cubic system being isotropic, those of the tetragonal and hexagonal being uniaxial, and the orthorhombic being biaxial). Optically biaxial crystals were afterwards shawn by J. F. W. Herschel and F. E. Neumann in 1822 and 1835 to be of three kinds, corresponding with the orthorhombic, monoclinic
an orthorhombic system. It was, however, noticed by Brewster himself that there are many apparent exceptions, and the "optical anomalies" of crystals have been the subject of much study. The intimate relations existing between various other physical properties of crystals and their external form have subsequently been gradually traced.

The symmetry of crystals, though recognized by Romé de l'Isle and Hauy, in that they replaced all similar edges and corners of their primitive forms by similar secondary planes, was not made use of in defining the six systems of crystallization, which depended solely on the lengths and inclinations of the axes of reference. It was, however, necessary to recognize that in each system there are certain forms which are only partially symmetrical, and these were described as hemihedral and tetratetrahedral forms (i.e., $\{2\}$, half-faced, and $\{4\}$, quarter-faced forms).

As a consequence of Hauy's law of rational intercepts, or, as it is more often called, the law of rational indices, it was proved by J. F. C. Hessel in 1830 that thirty-two types of symmetry are possible in crystals. Hesse's work remained overlooked for sixty years, but the most important result was independently arrived at by the same method by A. Gadolin in 1867. At the present day, crystals are considered as belonging to one or other of thirty-two classes, corresponding with these thirty-two types of symmetry, and are grouped in six systems. More recently, theories of crystal structure have attracted attention, and have been studied as purely geometrical problems of the homogeneous partitioning of space.

The historical development of the subject is treated more fully in the article CRISTALLOGRAPHY in the 9th edition of this work. Reference may also be made to C. M. Mars, Geschichte der Kristallkunde (Karlsruhe and Baden, 1829); W. Whewell, History of the Inductive Sciences, vol. iii. (3rd ed., London, 1857); F. von Kobell, Geschichte der Mineralogie von 1650-1860 (München, 1864); L. Fletcher, An Introduction to the Study of Minerals (British Museum Guide-Book); A. Fletcher, Recent Progress in Mineralogy and Crystallography (1832-1894) (Brit. Assoc. Rep., 1894).

I. CRISTALLOGRAPHY

The fundamental laws governing the form of crystals are:

1. Law of the Constancy of Angle.
2. Law of Symmetry.
3. Law of Rational Intercepts or Indices.

According to the first law, the angles between corresponding faces of all crystals of the same chemical substance are always the same and are characteristic of the substance.

(a) Symmetry of Crystals.

Crystals may, or may not, be symmetrical with respect to a point, a line or axis, and a plane; these "elements of symmetry" are spoken of as a centre of symmetry, an axis of symmetry, and a plane of symmetry respectively.

Centre of Symmetry.—Crystals which are centro-symmetrical have their faces arranged in parallel pairs; and the two parallel faces, situated on opposite sides of the centre ($O$ in fig. 3) are alike in surface characters, such as lustre, striations, and figures of the octahedron (fig. 3) is bounded by four pairs of parallel faces. Crystals belonging to many of the hemihedral and tetratetrahedral classes of the six systems of crystallization are devoid of a centre of symmetry.

Axes of Symmetry.—Consider the vertical axis joining the opposite corners $a$ and $d$ of an octahedron (fig. 3) and passing through its centre $O$; by rotating the crystal about this axis through a right angle ($90^\circ$) it reaches a position such that the orientation of its faces is the same as before the rotation; the face $a_1d_3$, for example, coming into the position of $a_2d_2$. During a complete rotation of $360^\circ$ ($=120^\circ \times 3$), the crystal occupies four such interchangeable positions. Such an axis of symmetry is known as a tetrad axis of symmetry. Other tetrad axes of the octahedron are $a_1d_1$ and $a_4d_4$.

An axis of symmetry of another kind is that which passing through the centre $O$ is normal to a face of the octahedron. By rotating the crystal about such an axis $Op$ (fig. 3) through an angle of $120^\circ$ those faces which are not perpendicular to the axis occupy interchangeable positions; for example, the face $a_1d_1$ comes into the position of $a_4d_4$, and $a_2d_2$ to $a_3d_3$. During a complete rotation of $360^\circ$ ($=120^\circ \times 3$) the crystal occupies similar positions three times. This is a triad axis of symmetry; and there being four pairs of parallel faces on an octahedron, there are four triad axes (only one of which is drawn in the figure).

An axis passing through the centre $O$ and the middle points $d$ of two opposite edges of the octahedron (fig. 4), i.e. parallel to the edges of the octahedron, is a dyad axis of symmetry. About this axis there may be rotation of $180^\circ$, and only twice in a complete revolution of $360^\circ$ ($=180^\circ \times 2$) is the crystal brought into interchangeable positions. There being six pairs of parallel edges on an octahedron, there are consequently six dyad axes of symmetry.

A regular octahedron thus possesses thirteen axes of symmetry (of three kinds), and there are the same number in the cube. Fig. 5 shows the three tetrad (or tetragonal) axes ($aa$), four triad (or trigonal) axes ($bb$), and six dyad (diad or diagonal) axes ($dd$).

Although not represented in the cubic system, there is still another kind of axis of symmetry possible in crystals. This is the hexad axis or hexagonal axis, for which the angle of rotation is $60^\circ$, or one-sixth of $360^\circ$. There can be only one hexad axis of symmetry in any crystal (see figs. 77-80).

Planes of Symmetry.—A regular octahedron can be divided into two equal and similar halves by a plane passing through the corners $a_1d_1d_3$ and the centre $O$ (fig. 3). One-half is the mirror reflection of the other in this plane, which is called a plane of symmetry. Corresponding planes on either side of a plane of symmetry are inclined to it at equal angles. The octahedron can also be divided by similar planes of symmetry passing through the corners $a_1d_1d_2$ and $a_2d_3d_4$. These three similar planes of symmetry are called the cubic planes of symmetry, since they are parallel to the faces of the cube (compare figs. 6-8, showing combinations of the octahedron and the cube).

A regular octahedron can also be divided symmetrically into two equal and similar portions by a plane passing through the corners $a_3$ and $d_1$, the middle points of $d$ of the edges $a_2d_2$ and $a_1d_2$, and the centre $O$ (fig. 4). This is called a dodecahedral plane of symmetry, being parallel to the face of the rhombic dodecahedron which truncates the edge $a_2d_2$ (compare fig. 14, showing a combination of the octahedron and rhombic dodecahedron). Another similar plane of symmetry is that passing through the corners $a_2d_2$ and the middle points of the edges $a_2d_3$ and $d_3a_4$, and altogether there are six dodecahedral planes of symmetry, two through each of the corners $a_1, a_2, d_3$ of the octahedron.
A regular octahedron and a cube are thus each symmetrical with respect to the following elements of symmetry: a centre of symmetry, thirteen axes of symmetry (of three kinds), and nine planes of symmetry (of two kinds). This degree of symmetry, which is the type corresponding to one of the classes of the cubic system, is the highest possible in crystals. As will be pointed out below, it is possible, however, for both the octahedron and the cube to be associated with fewer elements of symmetry than those just enumerated.

(b) Simple Forms and Combinations of Forms.

A single face \(a_0a_0\) (figs. 3 and 4) may be repeated by certain of the elements of symmetry to give the whole eight faces of the octahedron. Thus, by rotation about the vertical tetrad axis \(a_0\) the four upper faces are obtained; and by rotation of these about one or other of the horizontal tetrad axes the eight faces are derived. Or again, the same repetition of the faces may be arrived at by reflection across the three cubic planes of symmetry. (By reflection across the six dodecahedral planes of symmetry a tetrahedron only would result, but if this is associated with a centre of symmetry we obtain the octahedron.) Such a set of similar faces, obtained by symmetrical repetition, constitutes a "simple form." An octahedron thus consists of eight similar faces, and a cube is bounded by six faces all of which have the same surface characters, and parallel to each of which all the properties of the crystal are identical.

Examples of simple forms amongst crystallized substances are octahedra of alum and spinel and cubes of salt and fluor spar. More usually, however, two or more forms are present on a crystal, and we then have a combination of forms, or simply a "combination." Figs. 6, 7 and 8 represent combinations of the octahedron and the cube; in the first the faces of the cube predominate, and in the third those of the octahedron; fig. 7 with the two forms equally developed is called a cubo-octahedron. Each of these combined forms has all the elements of symmetry proper to the simple forms.

The simple forms, though referable to the same type of symmetry and axes of reference, are quite independent, and cannot be derived one from the other by symmetrical repetition, but, after the manner of Romé de l'Isle, they may be derived by replacing edges or corners by a face equally inclined to the faces forming the edges or corners; this is known as "truncation" (Lat. truncare, to cut off). Thus in fig. 6 the corners of the cube are symmetrically replaced or truncated by the faces of the octahedron, and in fig. 8 those of the octahedron are truncated by the cube.

(c) Law of Rational Intercepts.

For axes of reference, \(OX, OY, OZ\) (fig. 0), take any three edges formed by the intersection of three faces of a crystal. These axes are called the crystallographic axes, and the planes in which they lie the axial planes. A fourth face on the crystal intersecting these three axes in the points \(A, B, C\) is taken as the parametral plane, and the lengths \(OA : OB : OC\) are the parameters of the crystal. Any other face on the crystal may be referred to these axes and parameters by the ratio of the intercepts

\[
\frac{OA}{k} : \frac{OB}{l} : \frac{OC}{m}
\]

Thus for a face parallel to the plane \(ABe\) the intercepts are in the ratio \(OA : OB : Oe\), or

\[
\frac{OA}{1} : \frac{OB}{2} : \frac{OC}{1}
\]

and for a plane \(fgC\) they are \(Oj : Oq : OC\) or

\[
\frac{OA}{2} : \frac{OB}{1} : \frac{OC}{1}
\]

Now the important relation existing between the faces of a crystal is that the denominators \(k, l, m\) are usually, all rational whole numbers, rarely exceeding 6, and usually 0, 1, 2 or 3. Written in the form \((hkl)\), \(h\) referring to the axis \(OX\), \(k\) to \(OY\), and \(l\) to \(OZ\), they are spoken of as the indices (Millerian indices) of the face. Thus of a face parallel to the plane \(ABC\) the indices are \((111)\), of \(ABe\) they are \((112)\), and of \(fgC\) \((231)\). The indices are thus inversely proportional to the intercepts, and the law of rational intercepts is often spoken of as the "law of rational indices.”

The angular position of a face is thus completely fixed by its indices; and knowing the angles between the axial planes and the parametral plane all the angles of a crystal can be calculated when the indices of the faces are known.

Although any set of edges formed by the intersection of three planes may be chosen for the crystallographic axes, it is in practice usual to select certain edges related to the symmetry of the crystal, and usually coincident with axes of symmetry; for then the indices will be simpler and all faces of the same simple form will have a similar set of indices. The angles between the axes and the ratio of the lengths of the parameters \(OA : OB : OC\) (usually given as \(a : b : c\)) are spoken of as the "elements" of a crystal, and are constant for and characteristic of all crystals of the same substance.

The six systems of crystal forms, to be enumerated below, are defined by the relative inclinations of the crystallographic axes and the lengths of the parameters. In the cubic system, for example, the three crystallographic axes are taken parallel to the three tetrad axes of symmetry, i.e. parallel to the edges of the cube (fig. 5) or joining the opposite corners of the octahedron (fig. 3), and they are therefore all at right angles; the parametral plane \((111)\) is a face of the octahedron, and the parameters are all of equal length. The indices of the eight faces of the octahedron will then be \((111), (111), (111), (111), (111), (111), (111)\). The symbol \((111)\) indicates all the faces belonging to this simple form. The indices of the six faces of the cube are \((100), (010), (001), (001), (001), (001)\); here each face is parallel to two axes, i.e. intercepts them at infinity, so that the corresponding indices are zero.

(d) Zones.

An important consequence of the law of rational intercepts is the arrangement of the faces of a crystal in zones. All faces, whether they belong to one or more simple forms, which intersect in parallel edges are said to lie in the same zone. A line drawn through the centre \(O\) of the crystal parallel to these edges is called a zone-axis, and a plane perpendicular to this axis is called a zone-plane. On a cube, for example, there are three zones each containing four faces, the zone-axes being coincident with the three tetrad axes of symmetry. In the crystal of zircon (fig. 8) the eight prism-faces \(a, m, \&c.\) constitute a zone, denoted...
by \([a, m, a', \text{etc.}],\) with the vertical tetrad axis of symmetry as zone-axis. Again the faces \([a, x, p, c', p', x''', a''']\) lie in another zone, as may be seen by the parallel edges of intersection of the faces in figs. 87 and 88; three other similar zones may be traced on the same crystal.

The direction of the line of intersection (i.e. zone-axis) of any two planes \((hkl)\) and \((h'k'l')\) is given by the zone-indices \([uvw]\), where \(u = kl - h'l',\ v = hl - k'l',\) and \(w = hh' - kl'\), these being obtained from the face-indices by cross multiplication as follows:

\[
\begin{align*}
  h & \equiv k \equiv l \\
  h_1 & \equiv h_2 \equiv h_3.
\end{align*}
\]

Any other face \((h'k'l')\) lying in this zone must satisfy the equation

\[h_3 a + k_2 v + l w = 0.\]

This important relation connecting the indices of a face lying in a zone with the zone-indices is known as Weiss’s zone-law, having been first enunciated by C. S. Weiss. It may be pointed out that the indices of a face may be arrived at by adding together the indices of faces on either side of it and in the same zone; thus, \((312)\) in fig. 12 lies at the intersections of the three zones \([210, 101]\), \([201, 110]\) and \([211, 106]\), and is obtained by adding together each set of indices.

(c) Projection and Drawing of Crystals.

The shapes and relative sizes of the faces of a crystal being as a rule accidental, depending only on the distance of the faces from the centre of the crystal and not on their angular relations, it is often more convenient to consider only the directions of the normals to the faces. For this purpose projections are drawn, with the aid of which the zonal relations of a crystal are more readily studied and calculations are simplified.

The kind of projection most extensively used is the “stereographic projection.” The crystal is considered to be placed inside a sphere from the centre of which normals are drawn to all the faces of the crystal. The points at which these normals intersect the surface of the sphere are called the poles of the faces, and by these poles the positions of the faces are fixed. The poles of all faces in the same zone on the crystal will lie on a great circle of the sphere, which are therefore called zone-circles. The calculation of the angles between the normals of faces and between zone-circles is then performed by the ordinary methods of spherical trigonometry. The stereographic projection, however, represents the poles and zone-circles on a plane surface and not on a spherical surface. This is achieved by drawing lines joining all the poles of the faces with the north or south pole of the sphere and finding their points of intersection with the plane of the equatorial great circle, or primitive circle, of the sphere, the projection being represented on this plane. In fig. 10 is shown the stereographic projection, or stereogram, of a cubic crystal; \(a', a'', \text{etc.}\) are the poles of the faces of the cube. \(a', a'', \text{etc.}\) those of the octahedron, and \(a', a'', \text{etc.}\) those of the rhombic dodecahedron. The straight lines and circular arcs are the projections on the equatorial plane of the great circles in which the nine planes of symmetry intersect the sphere. A drawing of a crystal showing a combination of the cube, octahedron and rhombic dodecahedron is shown in fig. 11, in which the faces are lettered the same as the corresponding poles in the projection. From the zone-circles in the projection and the parallel edges in the drawing the zonal relations of the faces are readily seen: thus \([a'd'p'], [a'd'a'], [a'd'a'], \text{etc.}\) are zones. A stereographic projection of a rhombohedral crystal is given in fig. 72.

Another kind of projection in common use is the “gnomonic projection” (fig. 12). Here the plane of projection is tangent to the sphere, and normals to all the faces are drawn from the centre of the sphere to intersect the plane of projection. In this cubic crystal case all zones are represented by straight lines. Fig. 12 is the gnomonic projection of a cubic crystal, the plane of projection being tangent to the sphere at the pole of an octahedral face \((111)\), which is therefore in the centre of the projection. The indices of the several poles are given in the figure.

In drawing crystals the simple plans and elevations of descriptive geometry (e.g. the plans in the lower part of figs. 87 and 88) have sometimes the advantage of showing the symmetry of a crystal, but they give no idea of solidity. For instance, a cube would be represented merely by a square, and an octahedron by a square with lines joining the opposite corners. True perspective drawings are never used in the representation of crystals, since for showing the zonal relations it is important to preserve the parallelism of the edges. If, however, the eye, or point of vision, is regarded as being at an infinite distance from the object all the rays will be parallel, and edges which are parallel on the crystal will be represented by parallel lines in the drawing. The plane of the drawing, in which the parallel rays joining the corners of the crystals and the eye intersect, may be either perpendicular or oblique to the rays; in the former case we have an “orthographic” (ὀρθογραφικά, straight; γράφειν, to draw) drawing, and in the latter a “clino graphic” (κλινογραφία, to incline) drawing. Clinographic drawings are most frequently used for representing crystals. In representing, for example, a cubic crystal (fig. 11) a cube face \(a'\) is first placed parallel to the plane on which the crystal is to be projected and with one set of edges vertical; the crystal is then turned through a small angle about a vertical axis until a second cube face \(a''\) comes into view,
CRYSTALLOGRAPHY

and the eye is then raised so that a third cube face a may be seen.

(f) Crystal Systems and Classes.

According to the mutual inclinations of the crystallographic axes of reference and the lengths intercepted on them by the parametral plane, all crystals fall into one or other of six groups or systems, in each of which there are several classes depending on the degree of symmetry. In the brief description which follows of these six systems and thirty-two classes of crystals we shall proceed from those in which the symmetry is most complex to those in which it is simplest.

1. CUBIC SYSTEM
(Isometric; Regular; Octahedral; Tesseract).

In this system the three crystallographic axes of reference are all at right angles to each other and are equal in length. They are parallel to the edges of the cube, and in the different classes coincide either with cubic or dyad axes of symmetry. Five classes are included in this system, in all of which there are, besides other elements of symmetry, four triad axes.

In crystals of this system the angle between any two faces P and Q with the indices (hkl) and (pqr) is given by the equation

\[ \cos \theta = \frac{h \cdot k + k \cdot l + l \cdot h}{\sqrt{(h^2 + k^2 + l^2)(p^2 + q^2 + r^2)}}. \]

The angles between faces with the same indices are thus the same in all substances which crystallize in the cubic system; in other systems the angles vary with the substance and are characteristic of it.

HOLOSYMMETRIC CLASS
(Holoedrical (holo, whole); Hexakis-octahedral).

Crystals of this class possess the full number of elements of symmetry already mentioned above for the octahedron and the cube, viz.: three cubic planes of symmetry, six dodecahedral planes, three tetrad axes of symmetry, four triad axes, six dyad axes, and a centre of symmetry.

14. Combination of Rhombic Dodecahedron and Octahedron.

There are seven kinds of simple forms, viz.:

- Cube (Fig. 5). This is bounded by six square faces parallel to the cubic planes of symmetry, and also as the hexahedron. The angles between the faces are 90°, and the indices of the form are [100]. Salt, fluor spar and galena crystallize in simple cubes.

15. Triakis-octahedron. 16. Combination of Triakis-octahedron and Cube.

Octahedron (Fig. 3). Bounded by eight equilateral triangular faces perpendicular to the triad axes of symmetry. The angles between the faces are 70° 32' and 109° 28', and the indices are [111]. Spinel, magnetite and gold crystallize in simple octahedra. Combinations of the cube and octahedron are shown in Figs. 6-8.

Rhombic dodecahedron (Fig. 13). Bounded by twelve rhomb-shaped faces parallel to the six dodecahedral planes of symmetry. The angles between the normals to adjacent faces are 60°, and between other pairs of faces 90°; the indices are [111]. Garnet frequently crystallizes in this form. Fig. 14 shows the rhombic dodecahedron in combination with the octahedron.

In these three simple forms of the cubic system (which are shown in combination in Fig. 11) the angles between the faces and the indices are fixed and are the same in all crystals; in the four remaining simple forms they are variable.

Triakis-octahedron (three-faced octahedron) (Fig. 15). This solid is bounded by twenty-four isosceles triangles, and may be considered as an octahedron with a low triangular pyramid on each of its faces. As the inclinations of the faces may vary there is a series of these forms with the indices [211], [331], [332], &c. or in general [hkk].

Icositetrahedron (Fig. 17). Bounded by twenty-four trapezoidal faces, and hence sometimes called a 4-trapezohedron. The indices are [211], [311], [322], &c., or in general [hkk]. Auleite, leucite and garnet often crystallize in the simple form [211]. Combinations are shown in Figs. 18-20. The plane ABC in Fig. 9 is one face (112) of an icositetrahedron; the indices of the remaining faces in this octant being (211) and (121).

Icositetrahedron [211] and Rhombic Dodecahedron.

Tetrakis-hexahedron (four-faced cube) (Figs. 21 and 22). Like the triakis-octahedron this solid is also bounded by twenty-four isosceles triangles, but here grouped in fours over the cubic faces. The two figures show how, with different inclinations of the faces, the form may vary, approximating in Fig. 21 to the cube and in Fig. 22 to the rhombic dodecahedron. The angles over the edges lettered A are different from the angles over the edges lettered C. Each face is parallel to one of the crystallographic axes and intersects the two others in different lengths; the indices are therefore [210], [310], [320], and [320], cubic, &c., in general [hkk]. Fluorspar sometimes crystallizes in the simple form [310]; more usually, however, in combination with the cube (Fig. 23).

Hexakis-octahedron (Fig. 24). Here each face of the octahedron is replaced by six scalene triangles, so that altogether there are
CRYSTALLOGRAPHY

575

forty-eight faces. This is the greatest number of faces possible for any simple form in crystals. The faces are all oblique to the planes and axes of symmetry, and they intercept the three crystallographic axes in different lengths, hence the indices are all unequal, being in general \([hkl]\), or in particular cases \([321]\), \([421]\), \([423]\), etc. Such a form is known as the "general form" of the class. The interfacial angles over the three edges of each triangle are all different. These forms usually exist only in combination with other cubic forms (for example, fig. 25), but \([421]\) has been observed as a simple form on fluor spar.

Fig. 24.—Hexakis-octahedron. Fig. 25.—Combination of Hexakis-octahedron and Cube.

Several examples of substances which crystallize in this class have been mentioned above under the different forms; many others might be cited—for instance, the metals iron, copper, silver, gold, platinum, lead, mercury, and the non-metallic elements silicon and phosphorus.

TETRAHEDRAL CLASS

(Tetrahedral-hemihedral; Hexakis-tetrahedral).

In this class there is no centre of symmetry nor cubic planes of symmetry; the three tetrad axes become dyad axes of symmetry, and the four triad axes are polar, i.e. they are associated with different faces at their two ends. The other elements of symmetry (six dodecahedral planes and six dyad axes) are the same as in the last class.

Of the seven simple forms, the cube, rhombic dodecahedron and tetrakis-hexahedron are geometrically the same as before, though on actual crystals the faces will have different surface characters.

Fig. 26.—Tetrahedron. Fig. 27.—Deltoid Dodecahedron.

For instance, the cube faces will be striated parallel to only one of the diagonals (fig. 90), and etched figures on this face will be symmetrical with respect to two lines, instead of four as in the last class. The remaining simple forms have, however, only half the number of faces as the corresponding form in the last class, and are spoken of as "hemihedral with inclined faces." Tetrahedron (fig. 26). This is bounded by four equilateral triangles and is identical with the regular tetrahedron of geometry. The angles between the normals to the faces are \(109.28^\circ\). It may be derived from the octahedron by suppressing the alternate faces.

Fig. 28.—Triakis-tetrahedron. Fig. 29.—Hexakis-tetrahedron.

Deltoid \(^{1}\) dodecahedron (fig. 27). This is the hemihedral form of the triakis-octahedron; it has the indices \([hkh]\) and is bounded by twelve trapezoidal faces.

\(^{1}\) From the Greek letter \(\delta\) \(\kappa\) \(\rho\) \(\alpha\); in general, a triangular-shaped object; also an alternative name for a trapezoid.

Triakis-tetrahedron (fig. 28). The hemihedral form \([hkh]\) of the icositetrahedron; it is bounded by twelve isosceles triangles arranged in threes over the tetrahedron faces.

Hexakis-tetrahedron (fig. 29). The hemihedral form \([hkh]\) of the hexakis-octahedron; it is bounded by twenty-four scalene triangles and is the general form of the class.

Fig. 30.—Combination of two Tetrahedra.

Fig. 31.—Combination of Tetrahedron and Cube.

Corresponding to each of these hemihedral forms there is another geometrically similar form, differing, however, not only in orientation but also in actual crystals in the characters of the faces. Thus from the octahedron there may be derived two tetrahedra with the indices \([111]\) and \([211]\), which may be distinguished as positive and negative respectively. Fig. 30 shows a combination of

Fig. 32.—Combination of Tetrahedron, Cube and Rhombic Dodecahedron.

Fig. 33.—Combination of Tetrahedron and Rhombic Dodecahedron.

these two tetrahedra, and represents a crystal of blende, in which the four larger faces are dull and striated, whilst the four smaller are bright and smooth. Figs. 31-33 illustrate other tetrahedral combinations.

Tetrahedrite, blende, diamond, boracite and pharmacosiderite are substances which crystallize in this class.

PYRITOHELDAL \(^{1}\) CLASS

(Parallel-faced hemihedral; Dyakis-dodecahedral).

Crystals of this class possess three cubic planes of symmetry but no dodecahedrad planes. There are only three dyad axes of symmetry, which coincide with the crystallographic axes; in addition there are three triad axes and a centre of symmetry.

Here the cube, octahedron, rhombic dodecahedron, triakis-octahedron and icositetrahedron are geometrically the same as in the first class. The characters of the faces will, however, be different; thus the cube faces will be striated parallel to one edge only (fig. 99),

Fig. 34.—Pentagonal Dodecahedron. Dyakis-dodecahedron.

and triangular markings on the octahedron faces will be placed obliquely to the edges. The remaining simple forms are "hemihedral with parallel faces," and from the corresponding homohedral forms two hemihedral forms, a positive and a negative, may be derived.

Pentagonal dodecahedron (fig. 34). This is bounded by twelve pentagonal faces, but these are not regular pentagons, and the angles over the three sets of different edges are different. The regular dodecahedron of geometry, contained by twelve regular pentagons, is not a possible form in crystals. The indices are \([hkh]\); as a simple form \([210]\) is of very common occurrence in pyrites.

Dyakis-dodecahedron (fig. 35). This is the hemihedral form of

\(^{1}\) Named after pyrites, which crystallizes in a typical form of this class.
the hexakis-octahedron and has the indices \{400\}; it is bounded by twenty-four faces. As a simple form \{321\} is met with in pyrites.

Combinations (figs. 36–39) of these forms with the cube and the octahedron are common in pyrites. Fig. 37 resembles in general appearance the regular icosahedron of geometry, but only eight of the faces are equilateral triangles. Cobaltite, smithite and sulphasnides of the pyrites group of minerals crystallize in these forms. The alums also belong to this class; from an aqueous solution they crystallize as simple octahedra, sometimes with subordinate faces of the cube and rhombic dodecahedron, but from an acid solution as octahedra combined with the pentagonal dodecahedron \{210\}.

**Plaghihedral\(^1\) Class**
(Plagioclase-hemihedral; Pentagonal icositetrahedron; Gyroidal\(^2\)).

In this class there are the full number of axes of symmetry (three tetrad, four triad and six dyad), but no planes of symmetry and no centre of symmetry. Pentagonal icositetrahedron (fig. 40). This is the only simple form in this class which differs geometrically from those of the holosymmetr class. By suppressing either one or other set of alternate faces of the hexakis-octahedron two pentagonal icositetrahedra \{400\} and \{400\} are derived. These are each bounded by twenty-four irregular pentagons, and although similar to each other they are respectively right- and left-handed, one being the mirror image of the other; such similar but nonsuperposable forms are said to be enantiomorphous (le virus, opposite, and moph, form), and crystals showing such forms sometimes rotate the plane of polarization of plane-polarized light. Faces of a pentagonal icositetrahedron with high indices have been very rarely observed on crystals of cuprite, potassium chloride and ammonium chloride, but none of these are circular polarizing.

**Tetartohedral Class**
(Tetrahedral pentagonal dodecahedron).

Here, in addition to four polar triad axes, the only other elements of symmetry are three dyad axes, which coincide with the crystallographic axes. Six of the simple forms, the cube, tetrahedron, rhombic dodecahedron, deltoid dodecahedron, triakis-tetrahedron and pentagonal dodecahedron, are geometrically the same in this class as in either the tetrahedral or pyritohedral classes. The general form is the Tetrahedral pentagonal dodecahedron (fig. 41). This is bounded by twelve irregular pentagons, and is a tetartohedral or quarter-faced form of the hexakis-octahedron. Four such forms may be derived, the indices of which are \{400\}, \{400\}, \{400\} and \{400\}; the first pair are enantiomorphous with respect to one another, and so are the last pair. Barium nitrate, lead nitrate, sodium chloride and sodium bromate crystallize in this class, as also do the minerals ullmanite (NiSbS) and langbeinite (K\(_2\)Mg(SO\(_4\))\(_2\)).

**2. Tetragonal System**
(Pyramidal; Quadratic; Dimetric).

In this system the three crystallographic axes are all at right angles, but while two are equal in length and interchangeable the third is of a different length. The unequal axis is spoken of as the principal axis or morphological axis of the crystal, and it is always placed in a vertical position; in five of the seven classes of this system it coincides with the single tetrad axis of symmetry. The parameters are \(a: a: c\), where \(a\) refers to the two equal hori-

**Fig. 42.** Tetragonal Bipyramids.

**Fig. 43.** Tetragonal Bipyramids.

zontal axes, and \(c\) to the vertical axis; \(c\) may be either shorter (as in fig. 42) or longer (fig. 43) than \(a\). The ratio \(a: c\) is spoken of as the axial ratio of a crystal, and it is dependent on the angles between the faces. In all crystals of the same substance this ratio is constant, and is characteristic of the substance; for other substances crystalizing in the tetragonal system it will be different. For example, in cassiterite it is given as \(a: c = 1\): 0.67232 or simply as \(c = 0\).067232, \(a\) being unity; and in anatase as \(c = 1\): 1777.

**Holosymmetric Class**
(Holohedral; Ditetragonal bipyramidal).

Crystals of this class are symmetrical with respect to five planes, which are of three kinds; one is perpendicular to the principal axis, and the other four intersect in it; of the latter, two are perpendicular to the equal crystallographic axes, while the two others bisect the angles between them. There are five axes of symmetry, one tetrad and two pairs of dyad, each perpendicular to a plane of symmetry. Finally, there is a centre of symmetry.

There are seven kinds of simple forms, viz.:

- Tetragonal bipyramid of the first order (figs. 42 and 43). This is bounded by eight equal isosceles triangles. Equal lengths are intercepted on the two horizontal axes, and the indices are [111], [221], [112], &c., or in general \{400\}. The parametral plane with the intercepts \(a: a: c\) is a face of the bipyramid [111].

- Tetragonal bipyramid of the second order. This is also bounded by eight equal isosceles triangles, but differs from the last form in its position, four of the faces being parallel to each of the horizontal axes; the indices are therefore [101], [201], [102], &c., or [400].

Fig. 44 shows the relation between the tetragonal bipyramids.
of the first and second orders when the indices are [111] and [101] respectively: ABB is the face (111), and ACC is (101). A combination of these two forms is shown in fig. 45.

Ditetragonal bipyramid (fig. 46). This is the general form; it is bounded by sixteen scalene triangles, and all the indices are unequal, being [321], [4], or [44].

Tetragonal prism of the first order. The four faces intersect the horizontal axes in equal lengths and are parallel to the principal axis; the indices are therefore [110]. This form does not enclose space, and is therefore called an "open form," to distinguish it from a "closed form" like the tetragonal bipyramids and all the forms of the cubic system. An open form can exist only in combination with other forms; thus fig. 47 is a combination of the tetragonal prism [110] with the basal pinacoid [001]. If the faces [110] and [001] are of equal size such a figure will be geometrically a cube, since all the angles are right angles; the variety of apophyllite known as tesselate crystalizes in this form.

Tetragonal prism of the second order. This has the same number of faces as the last prism, but differs in position; each face being parallel to the vertical axis and one of the horizontal axes; the indices are [100].

Ditetragonal prism. This consists of eight faces all parallel to the principal axis and intercepting the horizontal axes in different lengths; the indices are [210], [320], &c., or [hkl].

Basal pinacoid (from πρaπσ, a tablet). This consists of a single pair of parallel faces perpendicular to the principal axis. It is therefore an open form and can exist only in combination (fig. 47).

Combinations of holohedral tetragonal forms are shown in figs. 47-49: fig. 48 is a combination of a bipyramid of the first order with one of the second order and the prism of the first order; fig. 49 a combination of a bipyramid of the first order with a ditetragonal bipyramid and the prism of the second order. Compare also figs. 87 and 88.

Examples of substances which crystallize in this class are cassiterite, rutile, anatase, zircon, thorite, vesuvianite, apophyllite, phosgenite, also boron, tin, mercuric iodide.

SCALENOHEDRAL CLASS
(Bisphenoidal-hemihedral).

Here there are only three dyad axes and two planes of symmetry, the former coinciding with the crystallographic axes and the latter bisecting the angles between the horizontal pair. The dyad axis of symmetry, which in this class coincides with the principal axis of the crystal, has certain of the characters of a tetrad axis, and is sometimes called a tetrad axis of "alternating symmetry"; a face on the upper half of the crystal if rotated through 90° about this axis and reflected across the equatorial plane falls into the position of a face on the lower half of the crystal. This kind of symmetry, with simultaneous rotation about an axis and reflection across a plane, is also called "composite symmetry."

In this class all except two of the simple forms are geometrically the same as in the holosymmetric class.

Bisphenoid (e.g., a wedge) (fig. 50). This is a double wedge-shaped solid bounded by four equal isosceles triangles; it has the indices [111], [211], [112], &c., or in general [hkl]. By suppressing either one or other set of alternate faces of the tetragonal bipyramid of the first order (fig. 42) two bisphenoids are derived, in the same way that two tetrahedra are derived from the regular octahedron.

Tetragonal scalenohedron or ditetragonal bisphenoid (fig. 51). This is bounded by eight scalene triangles and has the indices [hkl]. It may be considered as the hemihedral form of the ditetragonal bipyramid.

The crystal of chalcopyrite (CuFeS2) represented in fig. 52 is a combination of two bipyramids (P and P'), two bipyramids of the second order (b and c), and the basal pinacoid (a). Stannite (CuFeS3N), acid potassium phosphate (H3PO4), mercuricyanide, and urea (CO(NH2)2) also crystalize in this class.

PYRAMIDAL CLASS
(Hemimorphic-tetartohedral).

Here the only element of symmetry is the tetrad axis. The pyramids of the first [hkl], second [hkl], and third [hkl] orders each have only four faces at one or other end of the crystal, and are hemimorphic. All the simple forms are thus open forms.

Examples are wulfenite (PbMoO4) and barium antimony dextro-tartrate (Ba(SbO3)(C4H4O6)3·H2O).

DITETRAGONAL PYRAMIDAL CLASS
(Hemimorphic-hemihedral).

Here there are two pairs of vertical planes of symmetry intersecting in the tetrad axis. The pyramids [hkl] and [hkl] and the bipyramid [hkl] are all hemimorphic. Examples are iodosuccimide (C3H4O3N2), silver fluoride (AgF·H2O), and penta-erythrite (C12H8O4). No examples are known amongst minerals.

TRAPEZOHEDRAL CLASS
(Trapezohedral-hemihedral).

Here there are the full number of axes of symmetry, but no planes or centre of symmetry. The general form [hkl] is bounded by eight trapezoidal faces and is the tetragonal trapezohedron.
Examples are nickel sulphate (NiSO₄·6H₂O), guanidine carbonate ((CH₃N₃)₂H₂CO₃), strychine sulphate ((C₂H₅N₂O₂)₂H₂SO₄·6H₂O).

BISPHENOIDAL CLASS
(Bisphenoidal-tetartohedral).

Here there is only a single dyad axis of symmetry, which coincides with the principal axis. All the forms, except the prisms and basal pinacoid, are sphenoids. Crystals possessing this type of symmetry have not yet been observed.

3. ORTHORHOMBIC SYSTEM
(Rhombo; Prismatic; Triclinic).

In this system the three crystallographic axes are all at right angles, but they are of different lengths and not interchangeable. The parameters, or axial ratios, are a : b : c; these referring to the axes OX, OY and OZ respectively. The choice of a vertical axis, OZ = c, is arbitrary, and it is customary to place the longer of the two horizontal axes from left to right and take it as unity: this is called the "macro-axis" or "macro-diagonal" (from macro, long), whilst the shorter horizontal axis (OX = a) is called the "brachy-axis" or "brachy-diagonal" (from brachy, short). The axial ratios are constant for crystals of any one substance and are characteristic of it; for example, in barytes (BaSO₄), a : b : c = 0.8152 : 1 : 1.1156; in anglistenite (PbSO₄), a : b : c = 0.752 : 1 : 2.894; in cerussite (PbCO₃), a : b : c = 0.6100 : 1 : 0.7230.

There are three symmetry-classes in this system:—

HOLOHEDRAL CLASS
(Holohedral; Bipyramidal).

Here there are three dissimilar dyad axes of symmetry, each coinciding with a crystallographic axis; perpendicular to them are three dissimilar planes of symmetry; there is also a centre of symmetry. There are seven kinds of simple forms:—

Bipyramid (figs. 54 and 55). This is the general form and is bounded by eight scalene triangles; the indices are [111], [211], [221], [121], [321], [123], &c., or in general [hkl]. The crystallographic axes join opposite corners of these pyramids and in the fundamental bipyramidal [111] the parametral plane has the intercepts a : b : c. This is the only closed form in this class; the others are open forms and can exist only in combination. Sulphur often crystallizes in simple bipyramids.

Prism. This consists of four faces parallel to the vertical axis and intercepting the horizontal axes in the lengths a and b or in any multiples of these; the indices are therefore [110], [210], [120] or [h0l].

Macro-prism. This consists of four faces parallel to the macro-

[100] and the brachy-pinacoid [010] each consists of a pair of parallel faces respectively parallel to the macro- and the brachy-axis. Figs. 56-58 show combinations of these six open forms, and fig. 59 of a combination of the macro-pinacoid (a), brachy-pinacoid (b), a prism (m), a macro-prism (d), a brachy-prism (k), and a bipyramid (a).

Examples of substances crystallizing in this class are extremely numerous; amongst minerals are sulphur, stibnite, cerussite, chrysoberyll, topaz, olivine, niitre, barytes, and many others; and amongst artificial products iodine, potassium permanganate, potassium sulphate, benzene, barium formate, &c.

PYRAMIDAL CLASS
(Hemihorphic).

Here there is only one dyad axis in which two planes of symmetry intersect. The crystals are usually so placed that the dyad axis coincides with the vertical crystallographic axis, and the planes of symmetry are also vertical.

The pyramid [hkl] has only four faces at one end or other of the crystal. The macro-prism and the brachy-prism of the last class are here represented by the macro-dome and brachy-dome respectively, so called because of the resemblance of the pair of equally sloped faces to the roof of a house. The form [001] is a single plane at the top of the crystal, and is called a "pedion"; the parallel pedion [001] if present at the lower end of the crystal, constitutes a different form, the prisms [h00] and the macro- and brachy-pinacoids are geometrically the same in this class as in the last. Crystals of this class are therefore differently developed at the two ends and are said to be "hemihorphic."

Fig. 60 shows a crystal of the mineral hemimorphite (H₂ZnSiO₄) which is a combination of the brachy-pinacoid [010] and a prism.

Fig. 58.—Prism and Basal Pinacoid.
Fig. 59.—Crystal of Hypersthene. Holohedral Orthorhombic Combinations.

Fig. 61.—Orthorhombic Hemimorphite.

with the pedion (001), two brachy-domes and two macro-domes at the upper end, and a pyramid at the lower end. Examples of other substances belonging to this class are struvite (NH₄MgPO₄·6H₂O), bertrandite (H₂Be₂Si₃O₉), resorcin, and picric acid.

BISPHENOIDAL CLASS
(Hemihedral).

Here there are three dyad axes, but no planes of symmetry and no centre of symmetry. The general form [hkl] is a bisphenoid (fig. 61) bounded by four scalene triangles. The other simple forms are geometrically the same as in the holosymmetric class.

Examples: epsomite (Epsom salts, MgSO₄·7H₂O), goslarite (ZnSO₄·7H₂O), silver nitrate, sodium potassium dextro-tartarate (seignette salt, Na₂K₂C₆H₅O₇·4H₂O), potassium antimonyl dextro-tartarate (tartar-emic, K₂H₅O₇), and asparagus (C₆H₁₃NO₄·H₂O).
4. MONOCLINIC I SYSTEM

(Oblique; Monosymmetric)

In this system two of the angles between the crystallographic axes are right angles, but the third angle is oblique, and the axes are of unequal lengths. The axis which is perpendicular to the other two is taken as \( OZ \) (fig. 62) and is called the ortho-axis or orthodiagonal. Of the two other axes, the diagonals, one also is taken parallel to the edges of a prominently developed prismatic zone, and the clino-axis or clino-diagonal \( OX = \alpha \) parallel to the zone-axis of some other prominent zone on the crystal. The acute angle between the axes \( OX \) and \( OZ \) is usually denoted by \( \beta \), and it is necessary to know its magnitude, in addition to the axial ratios \( a : b : c \), before the crystal is completely determined. As in other systems, except the cubic, these elements, \( a : b : c \) and \( \beta \), are characteristic of the substance. Thus for gypsum \( a : b : c = 0:6585 : 1:0:5554 ; \beta = 86^\circ 57' \); and for cane-sugar \( a : b : c = 1:2595 : 1:0:8782 ; \beta = 76^\circ 30' \).

HOLOSYMMETRIC Class

(Holohedral; Prismatic)

Here there is a single plane of symmetry perpendicular to which is a dyad axis; there is also a centre of symmetry. The dyad axis coincides with the ortho-axis \( OY \), and the vertical axis \( OZ \) and the clino-axis \( OX \) lie in the plane of symmetry.

All the forms are open, being either pinacoids or prisms; the former consisting of a pair of parallel faces, and the latter of four faces intersecting in parallel edges and with a rhombic cross-section. The pair of faces parallel to the plane of symmetry is distinguished as the "clino-pinacoid" and has the indices \([101]\). The other pinacoids are all perpendicular to the plane of symmetry (and parallel to the ortho-axis); the one parallel to the vertical axis is called the "ortho-pinacoid" \([100]\) whilst that parallel to the clino-axis is the "basal pinacoid" \([001]\); pinacoids not parallel to the arbitrarily chosen clino- and vertical axes may have the indices \([101], [011], [102] \ldots \) \([k0l] \) or \([011], [001], [012] \ldots \) \([k0l] \), according to whether they lie in the obtuse or the acute axial angle. Of the prisms, those with edges (zone-axis) parallel to the clino-axis, and having indices \([102], [102] \ldots \) \([k0l] \), are called "clino-prisms"; those with edges parallel to the vertical axis, and with the indices \([101], [110], [012] \ldots \) \([k0l] \), are called simply "prisms." Prisms with edges parallel to neither of the axes \( OX \) and \( OZ \) have the indices \([011], [101], [112] \ldots \) \([k0l] \) or \([111] \ldots \) \([k0l] \).

Fig. 62.—Monoclinic Axes and Plane of Symmetry. Hemi-pyramid.

Fig. 63.—Crystal of Augite. Hemihedron.

and are usually called "hemi-pinacoids" (fig. 62); they are distinguished as negative or positive according to whether they lie in the obtuse or the acute axial angle \( \beta \).

Fig. 63 represents a crystal of augite bounded by the clino-pinacoid (\( \delta \)), the ortho-pinacoid (\( \gamma \)), a prism (\( \varphi \)), and a hemi-pyramid (\( \varphi \)).

HEMISYMMETRIC Class

(Sphenoiodal)

In this class the only element of symmetry is a single dyad axis, which is polar in character, being dissimilar at the two ends. The form \([101]\) perpendicular to the axis of symmetry consists of a single plane or pedion; the parallel face is dissimilar in character and belongs to the pedion \([010]\). The pinacoids \([100], [011], [101] \) and \([111] \) parallel to the axis of symmetry are geometrically the same in this class as in the holosymmetric class. The remaining forms consist each of only two planes on the same side of the axial plane \( OXZ \) and equally inclined to the dyad axis (e.g. in fig. 62 the two planes \( X Y Z \) and \( X YZ \)); such a wedge-shaped form is sometimes called a sphenoid.

Fig. 64.—Enantimorphous Crystals of Tartaric Acid.

Fig. 64 shows two crystals of tartaric acid, \( a \) a right-handed crystal of dextro-tartaric acid, and \( b \) a left-handed crystal of laevotartaric acid. The two crystals are enantimorphous, i.e. although they have the same interfacial angles they are not superposable, and being a pair of mirror images of each other. Other examples are potassium dextro-tartarate, cane-sugar, milk-sugar, quercite, lithium sulphate \((Li_{2}SO_{3} \cdot H_{2}O)\); amongst minerals the only example is the hydrocarbon fichtelite \((C_{2}H_{14})\).

CLINOHEDRAL Class

(Hemihedral; Domatic)

Crystals of this class are symmetrical only with respect to a single plane. The only form which is here geometrically the same as in the holosymmetric class is the clino-pinacoid \([101]\). The forms perpendicular to the plane of symmetry are all pedions, consisting of only one plane with the indices \([010], [001], [011], [012] \ldots \) \([k0l] \). The remaining forms, \([kk0], [0kl] \) and \([kkl] \), are domes or "goniods" (\( \gamma \)) (\( \varphi \)); an angle, and \( \varphi \)) (\( \varphi \)); an angle, and \( \varphi \)) (\( \varphi \)).

Fig. 65.—Crystal of Axinite.

5. ANORTHIC SYSTEM

(Triclinic)

In the anorthic (from \( \delta \), privative, and \( \delta \), right) or triclinic system none of the three crystallographic axes are at right angles, and they are all of unequal lengths, although they are not necessarily parallel to the crystallographic axes (fig. 66).

Fig. 66.—Axes and Plane of Symmetry.

HOLOSYMMETRIC Class

(Holohedral; Pinacoidal)

Here there is only a centre of symmetry. All the forms are pinacoids, each consisting of only two parallel faces. The indices of the three pinacoids parallel to the axial planes are \([100], [010] \) and \([001] \); those of pinacoids parallel to only one axis are \([k00], [k0l] \) and \([kkl] \); and the general form is \([kkl] \).

Several minerals crystallize in this class; for example, the plagio-clastic felspars, microcline, axinite (fig. 66), cyanite, amblygonite, chalcanthite \((Cu_{2}SO_{4} \cdot 3H_{2}O)\), saussolite \((H_{2}B_{4}O_{7})\); among artificial substances are potassium bichromate, racemic acid \((C_{2}H_{4}O_{2} \cdot 2H_{2}O)\), dibrom-para-nitrophenol, &c.

ASYMMETRIC Class

(Hemihedral; Pediad)

Crystals of this class are devoid of any elements of symmetry. All the forms are pedions, each consisting of a single plane, and they are thus hemihedral with respect to crystals of the last class. Although there is a total absence of symmetry, yet the faces are arranged in zones on the crystals.

Examples are calcium thiosulphate \((CaS_{2}O_{3} \cdot 6H_{2}O)\) and hydrogen stannium dextro-tartarate \((CH_{3}O_{3}H)_{2} \cdot Sr_{2}H_{2}O)\); there is no example amongst minerals.

6. HEXAGONAL SYSTEM

Crystals of this system are characterized by the presence of a single axis of either triad or hexad symmetry, which is spoken of as the "principal" or "morphological" axis. Those with a triad axis are grouped together in the rhombohedral or trigonal division, and those with a hexad axis in the hexagonal division. Both authors use these two divisions are treated as separate systems; or again the rhombohedral forms may be considered as hemihedral developments.

1 From \( \mu \), single, and \( \lambda \), single, to incline, since one axis is inclined to the plane of the other two axes, which are at right angles.
CRYSTALLOGRAPHY

of the hexagonal. On the other hand, hexagonal forms may be considered as a combination of two rhombohedral forms.

Owing to the peculiarities of symmetry associated with a single triad or hexad axis, the crystallographic axes of reference are different in this system from those used in the five other systems of crystals. Two methods of axial representation are in common use: rhombohedral axes being usually used for crystals of the rhombohedral division, and hexagonal axes for those of the hexagonal division; though sometimes either one or the other set is employed in both divisions.

Rhombohedral axes are taken parallel to the three sets of edges of a rhombohedron (fig. 66). They are inclined to one another at equal oblique angles, and they are all equally inclined to the principal axis; further, they are all of equal length and are interchangeable. With such a set of axes there can be no statement of an axial ratio, but the angle between the axes (or some other angle which may be calculated from this) may be given as a constant of the substance. Thus in calcite the rhombohedral angle (the angle between two faces of the fundamental rhombohedron) is 74° 55′, or the angle between the normal to a face of the rhombohedron and the principal axis is 44° 36′.

Hexagonal axes are four in number, viz., a vertical axis coinciding with the principal axis of the crystal, and the three horizontal axes inclined to one another at 60° in a plane perpendicular to the principal axis. The three horizontal axes, which are taken either parallel or perpendicular to the faces of a hexagonal prism (fig. 71) or the edge of a hexagonal bipyramid (fig. 70), are equal in length (a) but the vertical axis is of a different length (c). The indices of planes referred to such a set of axes are four in number; they are written as three sets of the first three (h+k+μ=0) referring to the horizontal axes and the last to the vertical axis. The ratio a:c of the parameters, or the axial ratio, is characteristic of all the crystals of the same substance. Thus for beryl (including emerald) a:c=1:0.4989 (often written c=a:0.4989); for zircons c=1:3564.

Rhombohedral Division.

In the rhombohedral or trigonal division of the hexagonal system there are seven symmetry-classes, all of which possess a single triad axis of symmetry.

Holosymmetric Class

(Holohedral; Ditrigonal scalenohedral).

In this class, which presents the commonest type of symmetry of the hexagonal system, the triad axis is associated with three similar planes of symmetry inclined to one another at 60° and intersecting in the triad axis; there are also three similar dyad axes, each perpendicular to a plane of symmetry, and a centre of symmetry. The seven simple forms are—

Rhombohedron (figs. 66 and 67), consisting of six rhomb-shaped faces with the edges all of equal lengths: the faces are perpendicular to the planes of symmetry. There are two sets of rhombohedra, distinguished respectively as direct and inverse; those of one set (fig. 66) are brought into the orientation of the other set (fig. 67) by a rotation of 60° or 180° about the principal axis. For the fundamental rhombohedron, parallel to the edges of which are the crystallographic axes of reference, the indices are [100]. Other rhombohedra may have the indices [211], [411], [110], [221], [111], &c., or in general [hkk]. (Compare fig. 72: for figures of other rhombohedra see Calcite.)

Scalenohedron (fig. 68), bounded by twelve scalenohedron triangles, and with the general indices [hkk]. The zig-zag lateral edges coincide with the similar edges of a rhombohedron, as shown in fig. 69; if the indices of the inscribed rhombohedron be [100], the indices of the scalenohedron represented in the figure are [201]. The scalenohedron [201] is a characteristic form of calcite, which for this reason is sometimes called "dog-tooth-spar." The angles over the three edges of a face of a scalenohedron are all different; the angles over three alternate polar edges are more obtuse than over the other three polar edges. Like the two sets of rhombohedra, there are also direct and inverse scalenohedra, which may be similar in form and angles, but different in orientation and indices.

Hexagonal bipyramid (fig. 70), bounded by twelve isosceles triangles each of which are equally inclined to two planes of symmetry. The indices are [210], [412], &c., or in general (hkl), where h+2k+l=0.

Fig. 70.—Hexagonal Bipyramid.

Fig. 71.—Hexagonal Prism and Basal Pinacoid.

Hexagonal prism of the first order (211), consisting of six faces parallel to the principal axis and perpendicular to the planes of symmetry; the angles between (the normals to) the faces are 60°.

Hexagonal prism of the second order (10T), consisting of six faces parallel to the principal axis and parallel to the planes of symmetry. The faces of this prism are inclined to 30° to those of the last prism.

Dihexagonal prism, consisting of twelve faces parallel to the principal axis and inclined to the planes of symmetry. There are two sets of angles between the faces. The indices are (23T), (43T) . . . [hkl], where h+6k+l=0.

Basal pinacoid (111), consisting of a pair of parallel faces perpendicular to the principal axis.

Fig. 71 shows a combination of a hexagonal prism (m) with the basal pinacoid (c). For figures of other combinations see Calcite and Corundum. The relation between rhombohedral forms and their indices are best studied with the aid of a stereographic projection (fig. 72); in this figure the thicker lines are the projections of the three planes of symmetry, and on these lie the poles of the rhombohedra (six of which are indicated).

Numerous substances, both natural and artificial, crystallize
in this class; for example, calcite, chalcopyrite, calamine, corundum (ruby and sapphire), haematite, chabazite; the elements arsenic, antimony, bismuth, selenium, tellurium and perhaps graphite; also ice, sodium nitrate, thymol, &c.

**Trigonal Pyramidal Class**

(Hemimorphic-hemihedral).

Here there are three similar planes of symmetry intersecting in the triad axis; there are no dyad axes and no centre of symmetry. The triad axis is unterminal and polar, and the crystals are differently developed at the two ends; crystals of this class are therefore pyro-electric. The forms are all open forms:-

Trigonal pyramid \([\text{hkl}]\), consisting of three faces which correspond to the three upper or the three lower faces of a rhombohedron of the holosymmetric class.

Trigonal pyramid \([\text{hkl}]\), of six faces, corresponding to the six upper or lower faces of the rhombohedron.

Hexagonal pyramid \([\text{hkl}]\) (where \(h-2k+l=0\)), of six faces, corresponding to the six upper or lower faces of the hexagonal pyramid.

Trigonal prism \([\text{221}]\) or \([\text{211}]\), two forms each consisting of three faces parallel to principal axis and perpendicular to the planes of symmetry.

Hexagonal prism \([\text{101}]\), which is geometrically the same as in the last class.

Trigonal prism \([\text{hkl}]\) (where \(h-k+l=0\)), of six faces parallel to the principal axis, and with two sets of axes between them.

Basal pedion \([\text{111}]\) or \([\text{11T}]\), each consisting of a single plane perpendicular to the principal axis.

Fig. 73 represents a crystal of tourmaline with the trigonal prism \([\text{21T}]\), hexagonal prism \([\text{10T}]\), and a trigonal pyramid at each end. Other substances crystallizing in this class are pyrargyrite, proustite, iodrite, AgI, greenschist, zinace, spangolite, sodium sulphate, tolyphenyl ketone.

**Trigonal Bipyramidal Class**

(Trigonal-orthohedral). Here there are three similar dyad axes inclined to one another at 60° and perpendicular to the triad axis. There are no planes or centre of symmetry. The dyad axes are unterminal, and are pyro-electric axes. Crystals of most substances of this class rotate the plane of polarization of a beam of light.

In this class the rhombohedra \([\text{hkl}]\), the hexagonal prism \([\text{hT}]\), and the basal pinacoid \([\text{11T}]\) are geometrically the same as in the holosymmetric class; the trigonal prism \([\text{10T}]\) and the ditrigonal prisms are as in the trigonal pyramidal class. The remaining simple forms are:-

Trigonal trapezohedron (fig. 74), bounded by six trapezoidal faces. There are two complementary and enantiomorphous trapezohedra, \([\text{hkl}]\) and \([\text{khl}]\), developed from the scalenohedron. Hexagonal trapezohedron \([\text{hkl}]\), bounded by six isosceles triangles; the indices are \([\text{hkl}]\), where \(h-2k+l=0\), as in the hexagonal bipyramid.

The only minerals crystallizing in this class are quartz (p.q.) and calcite, both of which rotate the plane of a beam of polarized light transmitted along the triad axis. Other examples are chalcopyrites of lead \((\text{PbS}_2\text{O}_4\cdot\text{H}_2\text{O})\), calcium and strontium, and of potassium \((\text{K}_2\text{S}_2\text{O}_4\cdot\text{H}_2\text{O})\), benzoil, matricite-steaoptene.

**Rhomboidal Class**

(Parallel-faced hemihedral).

The only elements of symmetry are the triad axis and a centre of symmetry. The general form \([\text{hkl}]\) is a rhombohedron, and is a hemihedral form, with parallel faces, of the scalenohedron. The form \([\text{khl}]\), where \(h-2k+l=0\), is also a rhombohedron, being the hemihedral form of the hexagonal bipyramid. The dihexagonal prism \([\text{hkl}]\) of the holosymmetric class becomes here a hexagonal prism. The rhombohedra \([\text{hkl}]\), hexagonal prisms \([\text{221}]\) and \([\text{101}]\), and the basal pinacoid \([\text{111}]\) are geometrically the same in this class.

Fig. 76 represents a crystal of diopside with the fundamental rhombohedron \([\text{100}]\) and the hexagonal prism of the second order \([\text{101}]\) combined with the rhombohedron \([\text{201}]\). Examples of minerals which crystallize in this class are phenacite, dioptase, willemite, dolomite, ilmenite and pyrophyllite; amongst artificial substances is ammonium periodate \((\text{NH}_4\text{H}_2\text{O}_3\cdot\text{H}_2\text{O})\).

**Trigonal Pyramidal Class**

(Hemimorphic-tetrahedral).

Here there is only the triad axis of symmetry, which is unterminal. The general form \([\text{hkl}]\) is a trigonal pyramid consisting of three faces at one end of the crystal. All other forms, in which the faces are neither parallel nor perpendicular to the triad axis, are trigonal pyramids. All the prisms are trigonal prisms; and perpendicular to these are two pedions.

The only substance known to crystallize in this class is sodium periodate \((\text{NaIO}_3\cdot\text{H}_2\text{O})\), the crystals of which are circularly polarizing.

**Trigonal Bipyramidal Class**

(Trigonal-bipyramidal). Here there is a plane of symmetry perpendicular to the triad axis. The trigonal pyramids of the last class are here trigonal bipyramids (fig. 75); the prisms are all trigonal prisms, and parallel to the plane of symmetry is the basal pinacoid. No example is known for this class.

**Hexagonal Division.**

In crystals of this division of the hexagonal system the principal axis is a hexad axis of symmetry. Hexagonal axes of reference are used: if rhombohedral axes be used many of the simple forms will have two sets of indices.

**Holosymmetric Class**

(Holohedral; Dihexagonal bipyramid)

Intersecting in the hexad axis are six planes of symmetry of two kinds, and perpendicular to them is an equatorial plane of symmetry. Perpendicular to the hexad axis are six dyad axes of two kinds and each perpendicular to a vertical plane of symmetry. The seven simple forms are:-

Dihexagonal bipyramid, bounded by twenty-four scalene triangles (fig. 77; \(\text{v} \) in fig. 80). The indices are \([\text{2131}]\), &c., or in general \([\text{hkl}]\). This form may be considered as a combination of two scalenohedra, a direct and an inverse, the faces of which differ in surface characters and often also in size.
Hexagonal bipyramid of the second order, bounded by twelve faces (e in figs. 79 and 80); indices \([1212], [1122] \ldots [h, h, 2h, l]\).

Dihexagonal prism, consisting of twelve faces parallel to the hexad axis and inclined to the vertical planes of symmetry; indices \([hkl]_0\).

Hexagonal prism of the first order \([0101]\), consisting of six faces parallel to the hexad axis and perpendicular to one set of three vertical planes of symmetry \((m \text{ in figs. } 71, 78-80)\).

Hexagonal prism of the second order \([1120]\), consisting of six faces also parallel to the hexad axis, but perpendicular to the other set of three vertical planes of symmetry \((a \text{ in fig. } 78)\).

Basal pinacoid \((0001)\), consisting of a pair of parallel planes perpendicular to the hexad axis \((c \text{ in figs. } 71, 78-80)\).

Beryl (emerald), connellite, zinc, magnesium and beryllium crystalize in this class.

Bipyramidal Class
(Parallel-faced hemihedral).

Here there is a plane of symmetry perpendicular to the hexad axis; there is also a centre of symmetry. All the closed forms are hexagonal bipyramids; the open forms are hexagonal prisms or the basal pinacoids. The general form \([hkl]_h\) is hemihedral with parallel faces with respect to the general form of the holosymmetric class.

Apatite (apatite), pyromorphite, mimetite and vanadinite possess this degree of symmetry.

Dihexagonal Pyramidal Class
(Hemimorphic-hemihedral).

Six planes of symmetry of two kinds intersect in the hexad axis. The hexad axis is unimetallic and all the forms are open forms. The general form \([hkl]_h\) consists of twelve faces at one end of the crystal, and is a dihexagonal hemihedron. The hexagonal pyramids \([hkl]_0\) and \((h, h, 2h, l)\) each consist of six faces at one end of the crystal. The pyramids are geometrically the same as in the holosymmetric class. Perpendicular to the hexad axis are the pedons \((0001)\) and \((0002)\). Iodolite (AgI), greenockite \((CaS)\), zetrite \((ZnS)\) and zincite \((ZnO)\) are the most placed in this class, but they more probably belong to the hemimorphic-hemihedral class of the rhombohedral division of this system.

Trapezohedral Class
(Trapezohedral-hemihedral).

Six dyad axes of two kinds are perpendicular to the hexad axis. The general form \([hkl]_h\) is the hexagonal trapezohedron bounded by twelve trapezoidal faces. The other simple forms are geometrically the same as in the holosymmetric class. Barium antimonylodexoxy-tartrate + potassium nitrate \((Ba(SbO_2)(C,H,O_2)\cdot KNO_3)\) and the corresponding lead salt crystalize in this class.

Hexagonal Pyramidal Class
(Hemimorphic-tetartohedral).

No other element is here associated with the hexad axis, which is unimetallic. The pyramids all consist of six faces at one end of the crystal, and prisms are all hexagonal prisms; perpendicular to the hexad axis are the pedons.

Lithium potassium sulphate, strontium-antimonylodexoxy-tartrate, and lead-nitromylodexoxy-tartrate are examples of this type of symmetry. The mineral nepheline is placed in this class because of the absence of symmetry in the etched figures on the prism faces (fig. 92).

(g) Regular Grouping of Crystals.

Crystals of the same kind when occurring together may sometimes be grouped in parallel position and so give rise to special structures, of which the dendritic from beryllium, a tree or branch-like aggregations of native copper or of magnetite and the fibrous structures of many minerals furnish examples. Sometimes, owing to changes in the surrounding conditions, the crystal may continue its growth with a different external form or colour, e.g. sceptre-quartz.

Regular intergrowths of crystals of totally different substances such as staurolite with cyanite, rutile with haematite, blende with chalcopyrite, calcite with sodium nitrate, are not uncommon. In these cases certain planes and edges of the two crystals are parallel. (See O. Mügge, "Die regelmäßigen Verwachsungen von Mineralien verschiedener Art," Neues Jahrbuch für Mineralogie, 1903, vol. xvi. pp. 335-475.)

But by far the most important kind of regular conjunction of crystals is that known as "twinning." Here two crystals or individuals of the same kind have grown together in a certain symmetrical manner, such that one portion of the twin may be brought into the position of the other by reflection across a plane or by rotation about an axis. The plane of reflection is called the twin-plane, and is parallel to one of the faces, or to a possible face, of the crystal: the axis of rotation, called the twin-axis, is parallel to one of the edges or perpendicular to a face of the crystal.

In the twinned crystal of gypsum represented in fig. 81 the two portions are symmetrical with respect to a plane parallel to the prismatic face (0001), i.e. a vertical plane perpendicular to the face of. B. Or we may consider the simple crystal (fig. 82) to be cut in half by this plane and one portion to be rotated through \(180^\circ\) about the face of the same plane. Such a crystal (fig. 81) is therefore described as being twinned on the plane (0001).

An octahedron (fig. 83) twinned on an octahedral face \((111)\) has the two portions symmetrical with respect to a plane perpendicular to this face (the large triangular face in the figure); and either portion may be brought into the position of the other by a rotation through \(180^\circ\) about the triad axis of symmetry which is perpendicular to this face. This kind of twinning is especially frequent in crystals of spinel, and is consequently often referred to as the "spinel twin-law."

In these two examples the surface of the union, or composition-plane, of the two portions is a regular surface coinciding with the twin-plane; such twinds are called "juxtaposition-twins." In other juxtaposed twins the plane of composition is, however, not necessarily the twin-plane. Another type of twin is the "interpenetration twin," an example of which is shown in fig. 84. Here one cube may be brought into the position of the other by a rotation of \(180^\circ\) about a triad axis, or by reflection across the octahedral plane which is perpendicular to this axis; the twin-plane is therefore \((111)\).

Since in many cases twinned crystals may be explained by the rotation of one portion through two right angles, R. M. Hally introduced the term "hemitrope" (from the Gr. 

\(\gamma\varepsilon\mu\tau\rho\alpha\), half, and 

\(\tau\rho\alpha\mu\nu\), a turn); the word "macle" had been earlier used by Romé d'Ivry. There are, however, some rare types of twins which cannot be explained by rotation about an axis, but only by reflection across a plane; these are known as "symmetric twins," a good example of which is furnished by one of the twins of chalcopyrite.

Twinned crystals may often be recognized by the presence of re-entrant angles between the faces of the two portions, as may be seen from the above figures. In some twinned crystals (e.g. quartz) there are, however, no re-entrant angles. On the other hand, two crystals accidentally grown together without any symmetrical relation between them will usually show some re-entrant angles, but this must not be taken to indicate the presence of twinning.

Twinning may be several times repeated on the same plane or on other similar planes of the crystal, giving rise to triplets,
quartets and other complex groupings. When often repeated on the same plane, the twinning is said to be "polysynthetic," and gives rise to a laminated structure in the crystal. Sometimes such a crystal (e.g. of corundum or pyroxene) may be readily broken in this direction, which is thus a "plane of parting," often closely resembling a true cleavage in character. In calcite and some other substances this lamellar twinning may be produced artificially by pressure (see below, Sect. II. (a), Glide-plane).

Another curious result of twinning is the production of forms which apparently display a higher degree of symmetry than that actually possessed by the substance. Twins of this kind are known as "mimetic-twins or pseudo-symmetric twins." Two hemihedral or hemispheric crystals (e.g. of diamond or of hemimorphite) are often united in twinned position to produce a group with apparently the same degree of symmetry as the holosymmetric class of the same system. Or again, a substance crystallizing in, say, the orthorhombic system (e.g. aragonite) may, by twinning, give rise to pseudo-hexagonal forms: and pseudo-cubic forms often result by the complex twinning of crystals (e.g. stannite, phillipsite, &c.) belonging to other systems. Many of the so-called "optical anomalies" of crystals may be explained by this pseudo-symmetric twinning.

(h) Irregularities of Growth of Crystals; Character of Faces.

Only rarely do actual crystals present the symmetrical appearance shown in the figures given above, in which similar faces are all represented as of equal size. It frequently happens that the crystal is so placed with respect to the liquid in which it grows that there will be a more rapid deposition of material on one part than on another; for instance, if the crystal be attached to some other solid it cannot grow in that direction. Only when a crystal is freely suspended in the mother-liquid and material for growth is supplied at the same rate on all sides does an equably developed form result.

Two misshapen or distorted octahedra are represented in figs. 85 and 86; the former is elongated in the direction of one of the edges of the octahedron, and the latter is flattened parallel to one pair of faces. It will be noticed in these figures that the edges in which the faces intersect have the same directions as before, though here there are additional edges not present in fig. 3. The angles (70° 32' or 109° 28') between the faces also remain the same; and the faces have the same inclinations to the axes and planes of symmetry as in the equably developed form. Although from a geometrical point of view these figures are no longer symmetrical with respect to the axes and planes of symmetry, yet crystallographically they are just as symmetrical as the ideally developed form, and, however much their irregularity of development, they still are regular (cubic) octahedra of crystallography. A remarkable case of irregular development is presented by the mineral cuprite, which is often found as well-developed octahedra; but in the variety known as chalcotrichite it occurs as a matted aggregate of delicate hairs, each of which is an individual crystal enormously elongated in the direction of an edge or diagonal of the cube.

The symmetry of actual crystals is sometimes so obscured by irregularities of growth that it can only be determined by measurement of the angles. An extreme case, where several of the planes have not been developed at all, is illustrated in fig. 87, which shows the actual shape of a crystal of zircon from Ceylon; the ideally developed form (fig. 88) is placed at the side for comparison, and the parallelism of the edges between corresponding faces will be noticed. This crystal is a combination of five simple forms, viz. two tetragonal prisms (a and m), two tetragonal bipyramids (e and p), and one ditetragonal bipyramid (z, with 16 faces).

The actual form, or "habit," of crystals may vary widely in different crystals of the same substance, these differences depending largely on the conditions under which the growth has taken place. The material may have crystallized from a fused

![Fig. 88.—Ideal Development. Crystal of Zircon (ciniographic drawings and plans).](image)
CRYSTALLOGRAPHY

The earliest theory of crystal structure of any moment is that of Hǻy, in which, as explained above, he conceived a crystal as composed of elements bounded by the cleavage planes of the crystal, the elements being arranged contiguously and along parallel lines. There is, however, no reason to suppose that matter is continuous throughout a crystalline body; in fact, it has been shown that space does separate the molecules, and we may therefore replace the contiguous elements of Hǻy by particles equidistantly distributed along parallel lines; by this artifice we retain the reticulated or net-like structure, but avoid the continuity of matter which characterizes Hǻy's theory; the permanence of crystal form being due to equilibrium between the intermolecular (and interatomic) forces. The crystal is thus conjectured as a "space-lattice," composed of three sets of parallel planes which enclose parallelopipeds, at the corners of which are placed the constituent molecules (or groups of molecules) of the crystal.

The geometrical theory of crystal structure (i.e. the determination of the varieties of crystal symmetry) is thus reduced to the mathematical problem: "In how many ways can space be partitioned?" M. L. Frankenheim, in 1835, determined this number as fifteen, but A. Bravais, in 1850, showed the identity of the results, and made the important discovery that the remaining fourteen cases can be represented by twelve types of paralleloipedes, which he designated by square, rectangular, cubic, octahedral, dodecahedral, and icosahedral.

A different view was adopted by L. Sohncke in 1879, who, by developing certain considerations published by Camille Jordan in 1869 on the possible types of regular repetition in space of identical parts, showed that the lattice-structure of Bravais was unnecessary, it being sufficient that each molecule of an indefinitely extended crystal, represented by its "point" (or centre of gravity), was identically situated with respect to the molecules surrounding it. The problem was thus reduced to the determination of the number of "point-systems" possible; Sohncke derived sixty-five such arrangements, which may also be obtained from the fourteen space-lattices of Bravais, by interpenetrating any one space-lattice with one or more identical lattices, with the condition that the resulting structure should conform with the homogeneity characteristic of crystals. But the sixty-five arrangements derived by Sohncke, of which Bravais' lattices are particular cases, did not complete the solution, for certain of the known types of crystal symmetry still remained unrepresented. These missing forms are characterized as being enantiomorphs consequently, with the introduction of this principle of repetition over a plane, i.e. mirror images. E. S. Fedorov (1890), A. Schoenflies (1891), and W. Barlow (1894), independently and by different methods, showed how Sohncke's theory of regular point-systems explained the whole thirty-two classes of crystal symmetry, 230 distinct types of crystal structure falling into these classes.

By considering the atoms instead of the centres of gravity of the molecules, Sohncke (Zeits. Kryst. Min., 1888, 14, p. 431) has generalized his theory, and propounded the structure of a crystal in the following terms: "A crystal consists of a finite number of interpenetrating regular point-systems, which all possess like and like-directed coincidence movements. Each separate point-system is occupied by similar material particles, but these may be different for the different interpenetrating partial systems which form the complex system." Or we may quote the words of P. von Groth (British Assoc. Rep., 1904): "A crystal—considered as indefinitely extended—consists of n
interpenetrating regular point-systems, each of which is formed of similar atoms; each of these point-systems is built up from a number of interpenetrating space-lattices, each of the latter being formed from similar atoms occupying parallel positions. All the space-lattices of the combined system are geometrically identical, or are characterized by the same elementary parallel-opippedon."

A complete résumé, with references to the literature, will be found in "Report on the Development of the Geometrical Theories of Crystal Structure, 1666-1901" (British Assoc. Rep., 1901).

II. PHYSICAL PROPERTIES OF CRYSTALS.

Many of the physical properties of crystals vary with the direction in the material, but are the same in certain directions; these are called the "crystallographic axes" or "crystallographic directions," which are the directions of the planes of the lattice, in contrast to the "external axes," which are the directions of the crystal as a whole. The symmetry of the external form of a crystal is related to its internal symmetry by the law of crystallography, which states that the crystal faces are planes parallel to the crystallographic axes.

(a) Elasticity and Cohesion.

The elastic constants of crystals are determined by similar methods to those employed with amorphous substances, only the bars and plates employed to determine the elastic constants having been replaced by crystals of the same material. The "elasticity surface" of a crystal is the surface on which the elastic constants are determined by the force required to deform the surface to a given extent. The elastic constants are determined by the force required to deform the surface to a given extent, and the surfaces expressing the compression coefficients are determined by the force required to deform the surface to a given extent.

In the case of homogenous elastic deformation, produced by pressure on all sides, the effect on the crystal is the same as that due to changes of temperature; and the surfaces expressing the compression coefficients in different directions have the same higher degree of symmetry, being either a sphere, spheroid or ellipsoid. When strained beyond the limits of elasticity, crystalline matter may suffer permanent deformation in one or other of two ways, or may be broken along cleavage surfaces or with an irregular fracture. In the case of plastic deformation, e.g., in a crystal of ice, the crystalline particles are displaced but without any change in their orientation. Crystals of some substances (e.g., para-azoxynitro) have such a high degree of plasticity that they are deformed even by their surface tension, and the crystals take the form of drops of doubly refractive liquid which are known as "liquid crystals." (See O. Lehmann, Flüssige Kristalle, Leipzig, 1904; F. R. Schenck, Kristallinische Flüssigkeiten und flüssige Kristalle, Leipzig, 1905.)

In the second, and more usual kind of permanent deformation without fracture, the particles glide along certain planes into a new (twinned) position of equilibrium. If a knife blade is pressed into the edge of a cleavage rhombohedron of calcite (at b, fig. 91) the portion abedc of the crystal will take up the position d'b'c'ode. The obtuse solid angle at a becomes acute (a'), whilst the acute angle at b becomes obtuse (b'); and the new surface d'ce is as bright and smooth as before. This result has been effected by the particles in successive layers gliding or rotating over each other, without separation, along planes parallel to cde. This plane, which truncates the edge of the rhombohedron and has the indices (110), is called a "glide-plane." The new portion is in twinned position with respect to the rest of the crystal, being a reflection of it across the plane cde, which is therefore a plane of twinning. This secondary twinning is often to be observed as a repeated lamination in the grains of calcite composing a crystalline limestone, or marble, which has been subjected to earth movements. Planes of gliding have been observed in many minerals (pyroxene, corundum, &c.) and their crystals may often be readily broken along these directions, which are thus "planes of parting" or "pseudo-cleavage."

The characteristic transverse striae, invariably present on the cleavage surfaces of stibnite and cyanite are due to secondary twinning along glide-planes, and have resulted from the bending of the crystals.

One of the most important characters of crystals is that of "cleavage"; there being certain plane directions across which the cohesion is a minimum, and along which the crystal may be readily split or cleaved. These directions are always parallel to a possible face on the crystal and usually one prominently developed and with simple indices, it being a face in which the crystal molecules are most closely packed. The directions of cleavage are symmetrically repeated according to the degree of symmetry possessed by the crystal. Thus in the cubic system, crystals of salt and galena cleave in three directions parallel to the faces of the cube (100), diamond and fluor spar cleave in four directions parallel to the octahedral faces (111), and blend in six directions parallel to the faces of the rhombic dodecahedron (110). In crystals of other systems there will be only a single direction of cleavage if this is parallel to the faces of a pinacoid; e.g., the basal pinacoid in tetragonal (as in apophyllite) or hexagonal crystals; or parallel (as in gypsum) or perpendicular (as in mica and chlorite) to the plane of symmetry of the monoclinic crystals. Calcite cleaves in three directions parallel to the faces of the primitive rhombohedron. Barytes, which crystallizes in the orthorhombic system, has two sets of cleavages, viz. a single cleavage parallel to the basal pinacoid (001) and also two directions parallel to the faces of the prism (110). In all of the examples just quoted the cleavage is described as perfect, since cleavage flakes with very smooth and bright surfaces may be readily detached from the crystals. Different substances, however, vary widely in their character of cleavage; in some it can only be described as good or distinct, whilst in others, e.g., quartz and alum, there is little or no tendency to split along certain directions and the surfaces of fracture are very uneven. Cleavage is therefore a character of considerable determinative value, especially for the purpose of distinguishing different minerals.

Another result of the presence in crystals of directions of minimum cohesion are the "perception figures," which are produced on a crystal-face when this is struck with a sharp point. A percussion figure consists of linear cracks radiating from the point of impact, which in their number and orientation agree with the symmetry of the face. Thus on a cube face of a crystal of salt the rays of the percussion figure are parallel to the diagonals of the face, whilst on an octahedral face a three-rayed star is developed. By pressing a blunt point into a crystal face a somewhat similar figure, known as a "pressure figure," is produced. Percussion and pressure figures are readily developed in cleavage sheets of mica (q.v.).

Closely allied to cohesion is the character of "hardness," which is often defined, and measured by, the resistance which a crystal face offers to scratching. That hardness is a character depending largely on crystalline structure is well illustrated by the two crystalline modifications of carbon: graphite is one of the softest of minerals, whilst diamond is the hardest of all. The hardness of crystals of different substances thus varies widely, and with minerals it is a character of considerable determinative value; for this purpose a scale of hardness is employed (see Mineralogy). Various attempts have been made with the view of obtaining accurate determinations of degrees of hardness, but with varying results; an instrument used for this purpose is called a sclerometer (from τύχον πάρα, hard). It may, however, be readily demonstrated that the degree of hardness on a crystal face varies with the direction, and that a curve expressing these relations possesses the same geometrical symmetry as the face itself. The mineral cyanite is remarkable in having widely different degrees of hardness on different faces of its crystals and in different directions on the same face.

Another result of the differences of cohesion in different directions is that crystals are corroded, or acted upon by chemical solvents, at different rates in different directions. This is strikingly shown when a sphere cut from a crystal, say of calcite
or quartz, is immersed in acid; after some time the resulting form is bounded by surfaces approximating to crystal faces, and has the same symmetry as that of the crystal from which the sphere was cut. When a crystal bounded by faces is immersed in a solvent the edges and corners become rounded and "prerossion faces" developed in their place; the faces become marked all over with minute pits or shallow depressions, and as these are extended by further solution they give place to small elevations on the corroded face. The sides of the pits and elevations are bounded by small faces which have the character of vicinal faces. These markings are known as "etched figures" or "corrosion figures," and they are extremely important aids in determining the symmetry of crystals. Etched figures are sometimes beautifully developed on the faces of natural crystals, e.g., of diamond, and they may be readily produced artificially with suitable solvents.

As an example, the etched figures on the faces of a hexagonal prism and the basal plane are illustrated in figs. 92-94 for three of the several symmetry-classes of the hexagonal system. The classes chosen are those in which nepheline, calcite and beryl (emerald) crystallize, and these minerals often have the simple form of crystal represented in the figures. In nepheline (fig. 92) the only element of symmetry is a hexad axis; the etched figures on the prism are therefore unsymmetrical, though similar on all the faces; the hexagonal markings on the basal plane have none of their edges parallel to the edges of the face; further the crystals being hemimorphic, the etched figures on the basal planes at the two ends will be different in character.

**CRYSTALLOGRAPHY**

![Fig. 92. Nepheline.](image1)
![Fig. 93. Calcite.](image2)
![Fig. 94. Beryl.](image3)

The facial development of crystals of nepheline give no indication of this type of symmetry, and the mineral has been referred to this class solely on the evidence afforded by the etched figures. In calcite there is a triad axis of symmetry parallel to the prism edges, three dyad axes each perpendicular to a pair of prism edges and three planes of symmetry perpendicular to the prism faces; the etched figures shown in fig. 93 will be seen to conform to all these elements of symmetry. There being in calcite also a center of symmetry, the equilateral triangles on the basal plane at the lower end of the crystal will be the same in form as those at the top, but they will occupy a reversed position. In beryl, which crystallizes in the holosymmetric class of the hexagonal system, the etched figures (fig. 94) display the fullest possible degree of symmetry; those on the prism faces are all similar and are each symmetrical with respect to two lines, and the hexagonal markings on the basal planes at both ends of the crystal are symmetrically placed with respect to six lines. A detailed account of the etched figures of crystals is given by H. Baumhauer, *Die Resultate der Atamethode in der kristallographischen Forschung* (Leipzig, 1894).

(b) Optical Properties.

The complex optical characters of crystals are not only of considerable interest theoretically, but are of the greatest practical importance. In the absence of external crystalline form, as with a faceted gem-stone, or with the minerals constituting a rock (thin, transparent sections of which are examined in the polarizing microscope), the mineral species may often be readily identified by the determination of some of the optical characters.

According to their action on transmitted plane-polarized light (see POLARIZATION OF LIGHT) all crystals may be referred to one or other of the five groups enumerated below. These groups correspond with the six systems of crystallization (in the second group two systems being included together). The several symmetry-classes of each system are optically the same, except in the rare cases of substances which are circularly polarizing.

(1) Optically isotropic crystals—corresponding with the cubic system.

(2) Optically uniaxial crystals—corresponding with the tetragonal and hexagonal systems.

(3) Optically biaxial crystals in which the three principal optical directions coincide with the three crystallographic axes—corresponding with the orthorhombic system.

(4) Optically biaxial crystals in which only one of the three principal optical directions coincides with a crystallographic axis—corresponding with the monoclinic system.

(5) Optically biaxial crystals in which there is no fixed and definite relation between the optical and crystallographic directions—corresponding with the anorthic system.

Optically Isotropic Crystals.—These belong to the cubic system, and like all other optically isotropic (from *lambdros*, character) bodies have only one index of refraction for light of each colour. They have no action on polarized light (except in crystals which are circularly polarizing); and when examined in the polarizing microscope they remain dark between crossed nicols, and cannot therefore be distinguished optically from amorphous substances, such as glass and opal.

Optically Uniaxial Crystals.—These belong to the tetragonal and hexagonal (including rhombohedral) systems, and between crystals of these systems there is no optical distinction. Such crystals are anisotropic or doubly refracting (see REFRACTION: DOUBLE); but for light travelling through them in a certain, single direction they are singly refracting. This direction, which is called the optic axis, is the same for light of all colours and at all temperatures; it coincides in direction with the principal crystallographic axis, which in tetragonal crystals is a tetrad (or dyad) axis of symmetry, and in the hexagonal system a triad or hexad axis.

For light of each colour there are two indices of refraction; namely, the ordinary index (ω) corresponding with the ordinary ray, which vibrates perpendicular to the optic axis; and the extraordinary index (ε) corresponding with the extraordinary ray, which vibrates parallel to the optic axis. If the ordinary index of refraction be greater than the extraordinary index, the crystal is said to be optically negative, whilst if less the crystal is optically positive. The difference between the two indices is a measure of the strength of the double refraction or birefringence. Thus in calcite, for sodium (D) light, ω = 1.6585 and ε = 1.4863; hence this substance is optically negative with a relatively high double refraction of ω-ε = 0.1722. In quartz ω = 1.5442, ε = 1.5533 and ω-ε = 0.0091; this mineral is therefore optically positive with low double refraction. The indices of refraction vary, not only for light of different colours, but also slightly with the temperature.

The optical characters of uniaxial crystals are symmetrical not only with respect to the full number of planes and axes of symmetry of tetragonal and hexagonal crystals, but also with respect to all vertical planes, i.e. all planes containing the optic axis. A surface expressing the optical relations of such crystals is thus an ellipsoid of revolution about the optic axis. In cubic crystals the corresponding surface is a sphere. In the *optical indicatrix* (L. Fletcher, *The Optical Indicatrix and the Transmission of Light in Crystals*), London, 1904) of the principal axis, or axis of rotation, is proportional to the index of refraction, (i.e. inversely proportional to the velocity) of the extraordinary rays, which vibrate along this axis and are transmitted in directions perpendicular thereto; the equatorial diameters are proportional to the index of refraction of the ordinary rays, which vibrate perpendicular to the optic axis. For positive uniaxial crystals the indicatrix is thus a prolate spheroid (egg-shaped), and for negative crystals an oblate spheroid (orange-shaped).

In "Fresnel's ellipsoid" the axis of rotation is proportional to
the velocity of the extraordinary ray, and the equatorial diameters proportional to the velocity of the ordinary ray; it is therefore an oblate spheroid for positive crystals, and a prolate spheroid for negative crystals. The “ray-surface,” or “wave-surface,” which represents the distances traversed by the rays during a given interval of time in various directions from a point of origin within the crystal, consists in uniaxial crystals of two sheets; namely, a sphere, corresponding to the ordinary rays, and an ellipsoid of revolution, corresponding to the extraordinary rays. The difference in form of the ray-surface for positive and negative crystals is shown in figs. 95 and 96.

When a uniaxial crystal is examined in a polariscope or polarizing microscope between crossed nicols (i.e. with the principal planes of the polarizer or analyser at right angles, and so producing a dark field of view) its behaviour differs according to the direction in which the light travels through the crystal, to the position of the crystal with respect to the principal planes of the nicols, and further, whether convergent or parallel polarized light is employed. A tetragonal or hexagonal crystal viewed, in parallel light, through the basal plane, i.e. along the principal axis, will remain dark as it is rotated between crossed nicols, and will thus not differ in its behaviour from a cubic crystal or other isotropic body. If, however, the crystal be viewed in any other direction, for example, through a prism face, it will, except in certain positions, have an action on the polarized light. A plane-polarized ray entering the crystal will be resolved into two polarized rays with the directions of vibration parallel to the vibration-directions in the crystal. These two rays on leaving the crystal will be combined again in the analyser, and a portion of the light transmitted through the instrument; the crystal will then show up brightly against the dark field. Further, owing to interference of these two rays in the analyser, the light will be brilliantly coloured, especially if the crystal be thin, or if a thin section of a crystal be examined. The particular colour seen will depend on the strength of the double refraction, the orientation of the crystal or section, and upon its thickness. If now, the crystal be rotated with the stage of the microscope, the nicols remaining fixed in position, the light transmitted through the instrument will vary in intensity, and in certain positions will be cut out altogether. The latter happens when the vibration-directions of the crystal are parallel to the vibration-directions of the nicols (these being indicated by cross-wires in the microscope). The crystal, now being dark, is said to be in position of extinction; and as it is turned through a complete rotation of 360° it will extinguish four times. If a prism face be viewed through, it will be seen that, when the crystal is in a position of extinction, the cross-wires of the microscope are parallel to the edges of the prism: the crystal is then said to give “straight extinction.”

In convergent light, between crossed nicols, a very different phenomenon is to be observed when a uniaxial crystal, or section of such a crystal, is placed with its optic axis coincident with the axis of the microscope. The rays of light, being convergent, do not travel in the direction of the optic axis and are therefore doubly refracted in the crystal; in the analyser the vibrations will be reduced to the same plane and there will be interference of the two sets of rays. The result is an “interference figure” (fig. 97), which consists of a number of brilliantly coloured concentric rings, each showing the colours of the spectrum of white light; intersecting the rings is a black cross, the arms of which are parallel to the principal planes of the nicols. If monochromatic light be used instead of white light, the rings will be alternately light and dark. The number and distance apart of the rings depend on the strength of the double refraction and on the thickness of the crystal. By observing the effect produced on such a uniaxial interference figure when a “quarter undulation (or wave-length) microplate” is superposed on the crystal, it may be at once decided whether the crystal is optically positive or negative. Such a simple test may, for example, be applied for distinguishing certain facetted gemstones: thus zircon and phenacite are optically positive, whilst corundum (ruby and sapphire) and beryl (emerald) are optically negative.

**Optically Biaxial Crystals.**—In these crystals there are three principal indices of refraction, denoted by α, β and γ; of these γ is the greatest and α the least (γ > β > α). The three principal vibration-directions, corresponding to these indices, are at right angles to each other, and are the directions of the three rectangular axes of the optical indicatrix. The indicatrix (fig. 98) is an ellipsoid with the lengths of its axes proportional to the refractive indices: \( OC = γ, OB = β, OA = α \), where \( OC > OB > OA \). The figure is symmetrical with respect to the principal planes \( OAC, OBC \).  

In Fresnel’s ellipsoid the three rectangular axes are proportional to \( 1/α, 1/β, \) and \( 1/γ \), and are usually denoted by \( a, b \) and \( c \) respectively, where \( a > b > c \); these have often been called “axes of optic elasticity,” a term now generally discarded.

The ray-surface (represented in fig. 99 by its sections in the three principal planes) is derived from the indicatrix in the following manner. A ray of light entering the crystal and travelling in the direction \( OA \) is resolved into polarized rays vibrating parallel to \( OB \) and \( OC \), and therefore propagated with the velocities \( 1/β \) and \( 1/γ \) respectively: distances \( OB \) and \( OC \) (fig. 99) proportional to these velocities are marked off in the direction \( OA \). Similarly, rays travelling along \( OC \) have the velocities \( 1/γ \) and \( 1/β \), and those along \( OB \) the velocities \( 1/α \) and \( 1/γ \). In the two directions \( OP_1 \) and \( OP_2 \) (fig. 98), perpendicular to the two circular sections \( P_1 P_1 \) and \( P_2 P_2 \) of the indicatrix, the two rays will be transmitted with the same velocity \( 1/β \). These two directions are called the optic axes (“primary optic axes”), though they have not all the properties which are associated with the optic axis of a uniaxial crystal. They have very nearly the same direction as the lines \( OS_1 \) and \( OS_2 \) in fig. 99, which are distinguished as the “secondary optic axes.” In most crystals the primary and secondary optic axes are inclined to each other at not more than a few minutes, so that for practical purposes there is no distinction between them.

The angle between \( OP_1 \) and \( OP_2 \) is called the “optic axial angle”; and the plane \( OAC \) in which they lie is called the “optic axial plane.” The angles between the optic axes are bisected by the vibration-directions \( OA \) and \( OC \); the one which
CRYSTALLOGRAPHY

bisects the acute angle being called the “acute bisectrix” or “first mean line,” and the other the “obtuse bisectrix” or “second mean line.” When the acute bisectrix coincides with the greatest axis OC of the indicatrix, i.e., the vibration-direction corresponding with the refractive index \( \gamma \) (as in figs. 98 and 99), the crystal is described as being optically positive; and when the acute bisectrix coincides with \( O \Delta \), the vibration-direction for the index \( \alpha \), the crystal is negative. The distinction between positive and negative biaxial crystals thus depends on the relative magnitude of the three principal indices of refraction; in positive crystals \( \beta \) is nearer to \( \alpha \) than to \( \gamma \), whilst in negative crystals the reverse is the case. Thus in topaz, which is optically positive, the refractive indices for sodium light are \( a = 1.6210 \), \( \beta = 1.6150 \), \( \gamma = 1.6244 \); and for orthoclase which is optically negative, \( a = 1.5190 \), \( \beta = 1.5327 \), \( \gamma = 1.5260 \). The difference \( \gamma - \alpha \) represents the strength of the double refraction.

Since the refractive indices vary both with the colour of the light and with the temperature, there will be for each colour and temperature slight differences in the form of both the indicatrix and the ray-surface; consequently there will be variations in the positions of the optic axes and in the size of the optic axial angle. This phenomenon is known as the “dispersion of the optic axes.” When the axial angle is greater for red light than for blue the character of the dispersion is expressed by \( \rho < \nu \), and when less by \( \rho > \nu \). In some crystals, e.g., brookite, the optic axes for red light and for blue light may be, at certain temperatures, in planes at right angles.

The type of interference figure exhibited by a biaxial crystal in convergent polarized light between crossed nicols is represented in figs. 100 and 101. The crystal must be viewed along the acute bisectrix, and for this purpose it is often necessary to cut a plate from the crystal perpendicular to this direction: sometimes, however, as in mica and topaz, a cleavage flake will be perpendicular to the acute bisectrix. When seen in white light, there are around each optic axis a series of brilliantly coloured ovals, which at the centre join to form an 8-shaped loop, whilst further from the centre the curvature of the rings is approximately that of lemniscates. In the position shown in fig. 100 the vibration-directions in the crystal are parallel to those of the nicols, and the figure is intersected by two black bands or “brushes” forming a cross. When, however, the crystal is rotated with the stage of the microscope the cross breaks up into the two branches of a hyperbola, and when the vibration-directions of the crystal are inclined at 45° to those of the nicols the figure is that shown in fig. 101. The points of emergence of the optic axes are at the middle of the hyperbolic brushes when the crystal is in the diagonal position: the size of the optic axial angle can therefore be directly measured with considerable accuracy.

In orthorhombic crystals the three principal vibration-directions coincide with the three crystallographic axes, and have therefore fixed positions in the crystal, which are the same for light of all colours and at all temperatures. The optical orientation of an orthorhombic crystal is completely defined by stating to which crystallographic planes the optic axial plane and the acute bisectrix are respectively parallel and perpendicular. Examined in parallel light between crossed nicols, such a crystal extinguishes parallel to the crystallographic axes, which are often parallel to the edges of a face or section; there is thus usually “straight extinction.” The interference figure seen in convergent polarized light is symmetrical about two lines at right angles.

In monoclinal crystals only one vibration-direction has a fixed position within the crystal, being parallel to the ortho-axis (i.e. perpendicular to the plane of symmetry or the plane \( o\alpha \)). The other two vibration-directions lie in the plane \( o\beta \), but they may vary in position for light of different colours and at different temperatures. In addition to dispersion of the optic axes there may thus, in crystals of this system, be also “dispersion of the bisectrices.” The latter may be of one or other of three kinds, according to which of the three vibration-directions coincides with the ortho-axis of the crystal. When the acute bisectrix is fixed in position, the optic axial planes for different colours may be crossed, and the interference figure will then be symmetrical with respect to a point only (“crossed dispersion”). When the obtuse bisectrix is fixed, the axial planes may be inclined to one another, and the interference figure is symmetrical only about a line which is perpendicular to the axial planes (“horizontal dispersion”). Finally, when the vibration-direction corresponding to the refractive index \( \beta \) or the “third mean line,” has a fixed position, the optic axial planes lie in the plane \( o\alpha \), but the acute bisectrix may vary in position in this plane; the interference figure will then be symmetrical only about a line joining the optic axes (“inclined dispersion”). Examples of substances exhibiting these three kinds of dispersion are borax, orthoclase and gypsum respectively. In orthoclase and gypsum, however, the optic axial angle gradually diminishes as the crystals are heated, and after passing through a uniaxial position they open out in a plane at right angles to the one they previously occupied; the character of the dispersion thus becomes reversed in the two examples quoted. When examined in parallel light between crossed nicols monoclinal crystals will give straight extinction only in faces and sections which are perpendicular to the plane of symmetry (or the plane \( o\alpha \)); in all other faces and sections the extinction-directions will be inclined to the edges of the crystal. The angles between these directions and edges are readily measured, and, being dependent on the optical orientation of the crystal, they are often characteristic of the substance (see, e.g., PLagioclase).

In anorthic crystals there is no relation between the optical and crystallographic directions, and the exact determination of the optical orientation is often a matter of considerable difficulty. The character of the dispersion of the bisectrices and optic axes is still more complex than in monoclinal crystals, and the interference figures are devoid of symmetry.

Absorption of Light in Crystals: Pleochroism.—In crystals other than those of the cubic system, rays of light with different vibration-directions will, as a rule, be differently absorbed; and the polarized rays emerging from the crystal may be of different intensities and (if the observation be made in white light and the crystal is coloured) differently coloured. Thus, in tourmaline the ordinary ray, which vibrates perpendicular to the principal axis, is almost completely absorbed, whilst the extraordinary ray is allowed to pass through the crystal. A plate of tourmaline cut parallel to the principal axis may therefore be used for producing a beam of polarized light, and two such plates used in crossed position form the polarizer or analyser of “tourmaline tongues,” with the aid of which the interference figures of crystals may be simply shown. Uniaxial (tetragonal and hexagonal) crystals when showing perceptible differences in colour for the ordinary and extraordinary rays are said to be “dichroic.” In biaxial (orthorhombic, monoclinic and anorthic) crystals, rays vibrating along each of the three principal vibration-directions may be differently absorbed, and, in coloured crystals, differently coloured; such crystals are therefore said to be “trichroic” or in general “pleochroic” (from πλεοχρος, more, and χρώλα, colour). The directions of maximum absorption in biaxial crystals have, however, no necessary relation with the axes of the indicatrix, unless these have fixed crystallographic directions, as in the orthorhombic system and the ortho-axis in the monoclinic.

In epilite it has been shown that the two directions
of maximum absorption which lie in the plane of symmetry are not even at right angles.

The pleochroism of some crystals is so strong that when they are viewed through in different directions they exhibit marked differences in colour. Thus a crystal of the mineral ilolite (called also dichroite because of its strong pleochroism) will be seen to be dark blue, pale blue or pale yellow according to which of three perpendicular directions it is viewed. The “face colours” seen directly in this way result, however, from the mixture of two “axial colours” belonging to rays vibrating in two directions.

In order to see the axial colours separately the crystal must be examined with a dichroscope, or in a polarizing microscope from which the analyser has been removed. The dichroscope, or dichroscope (fig. 102), consists of a cleavage rhombohedron of calcite (Iceland-spar) \( p \), on the ends of which glass prisms \( w \) are cemented: the lens \( l \) is focused on a small square aperture \( e \) in the tube of the instrument. The eye of the observer placed at \( e \) will see two images of the square aperture, and if a pleochroic crystal be placed in front of this aperture the two images will be differently coloured. On rotating this crystal with respect to the instrument the maximum difference in the colours will be obtained when the vibration-directions in the crystal coincide with those in the calcite. Such a simple instrument is especially useful for the examination of faceted gem-stones, even when they are mounted in their settings. A single glance suffices to distinguish between a ruby and a “spinel-ruby,” since the former is dichroic and the latter isotropic and therefore not dichroic.

The characteristic absorption bands in the spectrum of white light which has been transmitted through certain crystals, particularly those of salts of the cerium metals, will, of course, be different according to the direction of vibration of the rays.

Circular Polarization in Crystals.—Like the solutions of certain optically active organic substances, such as sugar and tartaric acid, some optically isotropic and uniaxial crystals possess the property of rotating the plane of polarization of a beam of light. In uniaxial (tетragonal and hexagonal) crystals it is only for light transmitted in the direction of the optic axis that there is rotatory action, but in isotropic (cubic) crystals all directions are the same in this respect. Examples of circularly polarizing cubic crystals are sodium chloride, sodium bromate, and sodium uranyl acetate; amongst tetragonal crystals are strychnine sulphate and guaianidine carbonate; amongst rhombohedral are quartz (\( q.v. \)) and cinnabar (\( q.v. \)) (these being the only two mineral substances in which the phenomenon has been observed), dichromates of potassium, lead, calcium and strontium, and sodium peroxide; and amongst hexagonal crystals is potassium lithium sulphate. Crystals of all these substances belong to one or other of the several symmetry-classes in which there are neither planes nor centre of symmetry, but only axes of symmetry. They crystallize in two complementary hemihedral forms, which are respectively right-handed and left-handed, i.e., enantiomorphic forms. Some other substances which crystallize in enantiomorphic forms are, however, only “optically active” when in solution (e.g. sugar and tartaric acid); and there are many other substances presenting this peculiarity of crystaline form which are not circularly polarizing either when crystallized or when in solution. Further, in the examples quoted above, the rotatory power is lost when the crystals are dissolved (except in the case of strychnine sulphate, which is only feebly active in solution). The rotatory power is thus due to different causes in the two cases, in the one depending on a spiral arrangement of the crystal particles, and in the other on the structure of the molecules themselves.

The circular polarization of crystals may be imitated by a pile of mica plates, each plate being turned through a small angle on the one below, thus giving a spiral arrangement to the pile.

"Optical Anomalies" of Crystals.—When, in 1818, Sir David Brewster established the important relations existing between the optical properties of crystals and their external form, he at the same time noticed many apparent exceptions. For example, he observed that crystals of leucite and boracite, which are cubic in external form, are always doubly refracting and optically biaxial, but with a complex internal structure; and that cubic crystals of garnet and analcite sometimes exhibit the same phenomena. Also some tetragonal and hexagonal crystals, e.g. apophyllite, vesuvianite, beryl, &c., which should normally be optically uniaxial, sometimes consist of several biaxial portions arranged in sectors or in a quite irregular manner. Such exceptions to the general rule have given rise to much discussion. They have often been considered to be due to internal strains in the crystals, set up as a result of cooling or by earth pressures, since similar phenomena are observed in chilled and compressed glasses and in dried gelatine. In many cases, however, as shown by E. Mallard, in 1876, the higher degree of symmetry exhibited by the external form of the crystals is the result of mimetic twinning, as in the pseudo-cubic crystals of leucite (\( q.v. \)) and boracite (\( q.v. \)). In other instances, substances not usually regarded as cubic, e.g. the monoclinic phillipite (\( q.v. \)), may by repeated twinning give rise to pseudo-cubic forms. In some cases it is probable that the substance originally crystalized in one modification at a higher temperature, and when the temperature fell it became transformed into a dimorphous modification, though still preserving the external form of the original crystal (see BORACITE). A summary of the literature is given by R. Braun, Die optischen Anomalien der Krystalle (Leipzig, 1891).

(c) Thermal Properties.

The thermal properties of crystals present certain points in common with the optical properties. Heat rays are transmitted and doubly refracted like light rays; and surfaces expressing this conductivity and taking different directions possess the same degree of symmetry and are related in the same way to the crystallographic axes as the ellipsoids expressing the optical relations. That crystals conduct heat at different rates in different directions is well illustrated by the following experiment. Two plates (fig. 103) cut from a crystal of quartz, one parallel to the principal axis and the other perpendicular to it, are coated with a thin layer of wax, and a hot wire is applied to a point on the surface. On the transverse section the wax will be melted in a circle, and on the longitudinal section (or on the natural prism faces) in an ellipse. The isothermal surface in a uniaxial crystal is therefore a spheroid; in cubic crystals it is a sphere; and in biaxial crystals an ellipsoid, the three axes of which coincide, in orthohombic crystals, with the crystallographic axes.

With change of temperature cubic crystals expand equally in all directions, and the angles between the faces are the same at all temperatures. In uniaxial crystals there are two principal planes of expansion; the one of Heat in Quartz.

measured in the direction of the principal axis may be either greater or less than that measured in directions perpendicular to this axis. A sphere cut from a uniaxial crystal at one temperature will be a spheroid at another temperature. In biaxial crystals there are different coefficients of expansion along three rectangular axes, and a sphere at one temperature will be an ellipsoid at another. A result of this is that for all crystals, except those belonging to the cubic system, the angles between the faces will vary, though only slightly, with changes of temperature. E. Mitscherlich found that the rhombohedral angle of calcite decreases 8° 37' as the crystal is raised in temperature from 0° to 100° C.
CRYSTALLOGRAPHY

As already mentioned, the optical properties of crystals vary considerably with the temperature. Such characters as specific heat and melting-point, which do not vary with the direction, are the same in crystals as in amorphous substances.

(d) Magnetic and Electrical Properties.

Crystals, like other bodies, are either paramagnetic or diamagnetic, i.e. they are either attracted or repelled by the pole of a magnet. In crystals other than those belonging to the cubic system, however, the relative strength of the induced magnetization is different in different directions within the mass. A sphere cut from a tetragonal or hexagonal (uniaxial) crystal will if freely suspended in a magnetic field (between the poles of a strong electro-magnet) take up a position such that the principal axis of the crystal is either parallel or perpendicular to the lines of force, or to a line joining the two poles of the magnet. Which of these two directions is taken by the axis depends on whether the crystal is paramagnetic or diamagnetic, and on whether the principal axis is the direction of maximum or minimum magnetization. The surface expressing the magnetic character in different directions is in uniaxial crystals a sphere; in cubic crystals it is a sphere. In orthorhombic, monoclinic and anortthic crystals there are three principal axes of magnetic induction, and the surface is an ellipsoid, which is related to the symmetry of the crystal in the same way as the ellipsoids expressing the thermal and optical properties.

Similarly, the dielectric constants of a non-conducting crystal may be expressed by a sphere, spheroid or ellipsoid. A sphere cut from a crystal will when suspended in an electro-magnetic field set itself so that the axis of maximum induction is parallel to the lines of force.

The electrical conductivity of crystals also varies with the direction, and bears the same relation to the symmetry as the thermal conductivity. In a rhombohedral crystal of haematite the electrical conductivity along the principal axis is only half as great as in directions perpendicular to this axis; whilst in a crystal of bismuth, which is also rhombohedral, the conductivities along and perpendicular to the axis are as 1:61.

Conducting crystals are thermo-electric: when placed against another conducting substance and the contact heated there will be a flow of electricity from one body to the other if the circuit be closed. The thermo-electric force depends not only on the nature of the substance, but also on the direction within the crystal, and may in general be expressed by an ellipsoid.

A remarkable case is, however, presented by minerals of the pyrites group: some crystals of pyrites are more strongly thermo-electrically positive than antimony, and others more negative than bismuth, so that the two when placed together give a stronger thermo-electric couple than do antimony and bismuth. In the thermo-electrically positive crystals of pyrites the faces of the pentagonal dodecahedron are striated parallel to the cubic edges, whilst in the rarer negative crystals the faces are striated perpendicular to these edges. Sometimes both sets of striations may be present, and the same crystals may change their character. The two groups of faces are the thermo-electrically positive and negative.

The most interesting relation between the symmetry of crystals and their electrical properties is that presented by the pyro-electrical phenomena of certain crystals. This is a phenomenon which may be readily observed, and one which often aids in the determination of the symmetry of crystals. It is exhibited by crystals in which there is no centre of symmetry, and the axes of symmetry are uniterminal or polar in character, being associated with different faces on the crystal at their two ends. When a non-conducting crystal possessing this morphic type of symmetry is subjected to changes of temperature a charge of positive electricity will be developed on the faces in the region of one end of the uniterminal axis, whilst the faces at the opposite end will be negatively charged. With rising temperature the pole which becomes positively charged is called the "analogous pole," and that negatively charged the "antilogous pole"; with falling temperature the charges are reversed. This phenomenon was first observed in crystals of tourmaline, the principal axis of which is a uniterminal triad axis of symmetry. In crystals of quartz there are three uniterminal dyad axes of symmetry perpendicular to the principal triad axis (which is here similar at its two ends): the dyad axes emerge at the edges of the hexagonal prism, alternate edges of which become positively and negatively charged on change of temperature. In boracite there are four uniterminal triad axes, and the faces of the two tetrahedra perpendicular to them will bear opposite charges. Other examples of pyro-electric crystals are the orthorhombic mineral hemimorphite (called also, for this reason, "electric calamine") and the monoclinic tartaric acid and cane-sugar, each of which possesses a uniterminal dyad axis of symmetry. In some exceptional cases, e.g. axinite, prehnite, &c., there is no apparent relation between the distribution of the pyro-electric charges and the symmetry of the crystals.

The distribution of the electric charges may be made visible by the following simple method, which may be applied even with minute crystals observed under the microscope. A finely powdered mixture of red-lead and sulphur is dusted through a sieve over the cooling crystal. In passing through the sieve the particles of red-lead and sulphur become electrified by mutual friction, the former positively and the latter negatively. The red-lead is therefore attracted to the negatively charged parts of the crystal and the sulphur to those positively charged, and the distribution of the charges over the whole crystal becomes mapped out in the two colours red and yellow.

Since, when a crystal changes in temperature, it also expands or contracts, a similar distribution of "piezo-electric" (from πίεσω
τερ, to press) charges are developed when a crystal is subjected to changes of pressure in the direction of a uniterminal axis of symmetry. Thus increasing pressure along the principal axis of a tourmaline crystal produces the same electric charges as decreasing temperature.

III. RELATIONS BETWEEN CRYSTALLINE FORM AND CHEMICAL COMPOSITION.

That the general and physical characters of a chemical substance are profoundly modified by crystalline structure is strikingly illustrated by the two crystalline modifications of the element carbon—namely, diamond and graphite. The former crystallizes in the cubic system, possesses four directions of perfect cleavage, is extremely hard and transparent, is a non-conductor of heat and electricity, and has a specific gravity of 3.5; whilst graphite crystallizes in the hexagonal system, cleaves in a single direction, is very soft and opaque, is a good conductor of heat and electricity, and has a specific gravity of 2.2. Such substances, which are identical in chemical composition, but different in crystalline form and consequently in their physical properties, are said to be "dimorphous." Numerous examples of dimorphous substances are known; for instance, calcium carbonate occurs in nature either as calcite or as aragonite, the former being rhombohedral and the latter orthorhombic; mercuric iodide crystallizes from solutions as red tetragonal crystals, and by sublimation as yellow orthorhombic crystals. Some substances crystallize in three different modifications, and these are said to be "triphrous"; for example, titanium dioxide is met with as the minerals rutile, anatase and brookit (q.v.). In general, or in cases where more than three crystalline modifications are known (e.g. in sulphur no less than six have been described), the term "polymorphism" is applied.

On the other hand, substances which are chemically quite distinct may exhibit similarity of crystalline form. For example, the minerals iodyrite (AgI), greenockite (CdS), and zincite (ZnO) are practically identical in crystalline form; calcite (CaCO₃) and sodium nitrate (NaNO₃); celestite (SrSO₄) and marcassite (FeS₂); epidote and azurite; and many others, some of which are no doubt only accidental coincidences. Such substances are said to be "homoeomorphous" (Gr. ἴδους, like, and μορφή, form).

Similarity of crystalline form in substances which are chemically related is frequently met with and is a relation of much
importance: such substances are described as being “isomorphous.” Amongst minerals there are many examples of isomorphous groups, e.g. the rhombohedral carbonates, garnet (q.v.), plagioclase (q.v.); and amongst crystals of artificially prepared salts isomorphism is equally common, e.g. the sulphates and selenates of potassium, rubidium and caesium. The rhombohedral carbonates have the general formula R\(^2\)CO\(_3\), where R represents calcium, magnesium, iron, manganese, zinc, cobalt or lead, and the different minerals (calcite, ankerite, magnesite, chalchite, rhodochrosite and calamine (q.v.)) of the group are not only similar in crystal form, cleavage, optical and other characters, but the angles between corresponding faces do not differ by more than 1° or 2°. Further, equivalent amounts of the different chemical elements represented by R\(^2\) are mutually replaceable, and two or more of these elements may be present together in the same crystal, which is then spoken of as a “mixed crystal” or isomorphous mixture.

In another isomorphous series of carbonates with the same general formula R\(^2\)CO\(_3\), where R\(^2\) represents calcium, strontium, barium, lead or zinc, the crystals are orthorhombic in form, and are thus dimorphous with those of the previous group (e.g. calcite and aragonite, the other members being only represented by isomorphous replacements). Such a relation is known as “isodimorphism.” An even better example of this is presented by the arsenic and antimony trioxides, each of which occurs as two distinct minerals:—

\[ \text{As}_2\text{O}_3, \text{Arsenolite (organic)}; \text{Clausetite (monoclinic).} \]

\[ \text{Sb}_2\text{O}_3, \text{Senarmontite (cubic); Valientzite (orthorhombic).} \]

Clausetite and valientzitie though crystallizing in different systems have the same cleavages and very nearly the same angles, and are strictly isomorphous.

Substances which form isomorphous groups also frequently crystallize as double salts. For instance, amongst the carbonates quoted above are the minerals dolomite (CaMg\(_2\)CO\(_3\)) and barytocalcic (Ca\(_2\)Ba\(_2\)CO\(_3\)). Crystals of barytocalcic (q.v.) are monoclinic; and those of dolomite (q.v.), though closely related to calcite in angles and cleavage, possess a different degree of symmetry, and the specific gravity is not such as would result by a simple isomorphous mixture of the two carbonates. A similar case is presented by artificial crystals of silver nitrate and potassium nitrate. Somewhat analogous to double salts are the molecular compounds formed by the introduction of “water of crystallization,” “alcohol of crystallization,” &c. Thus sodium sulphate may crystallize alone or with either seven or ten molecules of water, giving rise to three crystallographically distinct substances.

A relation of another kind is the alteration in crystal form resulting from the replacement in the chemical molecule of one or more atoms by atoms or radicles of a different kind. This is known as a “morphotropic” relation (Gr. μορφή, form, τρόπος, habit). Thus when some of the hydrogen atoms of benzene are replaced by (OH) and (NO\(_3\)) groups the orthorhombic system of crystallization remains the same as before, and the crystallographic axis a is not much affected, but the axis c varies considerably:

\[
\begin{align*}
a : b : c \\
0.891 : 1 : 0.979
\end{align*}
\]

\[
\begin{align*}
\text{Benzeno, C}_6\text{H}_6 & \quad \text{Resorcin, C}_6\text{H}_4(\text{OH})_2 & \quad \text{Picric acid, C}_6\text{H}_4(\text{OH})(\text{NO}_3)_2 \\
0.910 : 1 : 0.540 & \quad 0.937 : 1 : 0.974
\end{align*}
\]

A striking example of morphotropy is shown by the humite (q.v.) group of minerals: successive additions of the group MgSiO\(_3\) to the molecule produce successive increases in the length of the vertical crystallographic axis.

In some instances the replacement of one atom by another produces little or no influence on the crystalline form; this happens in complex molecules of high molecular weight, the “mass effect” of which has a controlling influence on the isomorphism. An example of this is seen in the replacement of sodium or potassium by lead in the alunite (q.v.) group of minerals, or again in such a complex mineral as tourmaline, which, though varying widely in chemical composition, exhibits no variation in crystalline form.

For the purpose of comparing the crystalline forms of isomorphous and morphotropic substances it is usual to quote the angles or the axial ratios of the crystal, as in the table of benzene derivatives quoted above. A more accurate comparison is, however, given by the “molecular volume,” which are calculated from the axial ratios and the molecular volumes; they express the relative distances apart of the crystal molecules in the axial directions.

The two isomorphs of substances, such as tartaric acid, which in solution rotate the plane of polarized light either to the right or to the left, crystallize in related but enantiomorphous forms.

References.—An introduction to crystallography is given in most textbooks of mineralogy, e.g. those of H. A. Miers and of E. S. Dana (see Mineralogy). The standard work treating of the subject generally is that of P. Groth, Physikalische Kristallographie (4th ed., Leipzig, 1905). A condensed summary is given by A. J. Moses, The Characters of Crystals (New York, 1896).

For geometrical crystallography, dealing exclusively with the external form of crystals, reference may be made to N. Story-Maskelyne, Crystallography, a Treatise on the Morphology of Crystals (Oxford, 1883) and W. J. Lewis, A Treatise on Crystallography (Cambridge, 1899). Theories of crystal structure are discussed by L. Söhncke, Entwickelung einer Theorie der Krystallsstruktur (Leipzig, 1879); A. Schoenflies, Krystalsysteme und Krystalsstruktur (Leipzig, 1891); and E. Hilbert, Isomorphie, Krystalloide und Krystallography and the Theory of Groups of Movements (Oxford, 1903).

The physical properties of crystals are treated by L. Tiebie, Physikalische Krystallographie (Leipzig, 1891), and in a more elementary work by his Transactions of the Krystallographisch-Physikalischen Gesellschaft (Leipzig, 1896); E. Maller, Traité de cristallographie, Cristallographie physique (Paris, 1884); C. Soret, Éléments de cristallographie physique (Geneva and Paris, 1893).

For an account of the relations between crystalline form and chemical composition, see A. Arzruni, Physikalische Chemie der Krystalle (Braunschweig, 1893); A. Fock, An Introduction to Chemical Crystallography, translated by W. J. Pope (Oxford, 1895); P. Groth, An Introduction to Chemical Crystallography, translated by R. F. T. Soret (London, 1896); E. Hilbert, Einführung in die Krystallographie und die Physikalische Chemie, 4th ed. (Leipzig, 1903); and of minerals the treatises of J. D. Dana and C. Hintze.

CRYSTAL PALACE—CSERGENCY

CRYSTAL PALACE, THE, a well-known English resort, standing high up in grounds just outside the southern boundary of the county of London, in the neighbourhood of Sydenham. The building, chiefly of iron and glass, is flanked by two towers and is visible from far over the metropolis. It measures 1608 ft. in length by 384 ft. across the transepts, and was opened in its present site in 1854. The materials, however, were mainly those of the hall set up in Hyde Park for the Great Exhibition of 1851. The designer was Sir Joseph Paxton. In the palace there are various permanent exhibitions, while special exhibitions are held from time to time, also concerts, winter pantomimes and other entertainments. In the extensive grounds there is accommodation for all kinds of games: the final tie of the Association Football Cup and other important football matches are played here, and there are also displays of fireworks and other entertainments.

CSERGENCY, ANTON (1822–1886), Hungarian publicist, and a historical writer of great influence on his time, was born at Nagyvárad on the 2nd of June 1822. He took, at an early date, a very active part in the literary and political movements immediately preceding the Hungarian Revolution of 1848. He and Baron Sigismund Kemény may be considered as the two founders of high-class Magyar journalism. After 1867 the greatest of modern Hungarian statesmen, Francis Déak, attached Cserengy to his personal service, and many of the momentous state documents inspired or suggested by Déak were drawn up by Cserengy. In that manner his influence, as represented by the text of many a statute regulating the relations between Austria and Hungary, is one of an abiding character. As a historical writer he excelled chiefly in brilliant and thoughtful essays on the leading political personalities of his time, such as Paul Nagy, Bertalan, Szemere and others. He also commenced a translation of Macaulay's History. He died at Budapest on the 13th of July 1886.
CSIKY—

CSIKY, GREGOR (1842–1892), Hungarian dramatist, was born on the 8th of December 1842 at Pankota, in the county of Arad. He studied Roman Catholic theology at Pest and Vienna, and was professor in the Priests' College at Temesvár from 1870 to 1878. In the latter year, however, he joined the Evangelical Church, and took up literature. Beginning with novels and works on ecclesiastical history, which met with some recognition, he ultimately devoted himself to writing for the stage. Here his success was immediate. In his As ellenálláthatalám ("L'Irrésistible"), which obtained a prize from the Hungarian Academy, he showed the distinctive features of his talent—directness, freshness, realistic vigour, and highly individual style. In rapid succession he enriched Hungarian literature with realistic genre-pictures, such as A Proletárok ("Proletariát", Budorokh ("Bubbles"), Két szelem ("Two Loves"), A ságynéniős ("The Bashful"), Aikhalia, etc., in all of which he seized on one or another feature or type of modern life, dramatizing it with unusual intensity, qualified by chaste and well-balanced diction. Of the latter, his classical studies may, no doubt, be taken as the inspiration, and his translation of Sophocles and Plautus will long rank with the most successful of Magyar translations of the ancient classics. Among the best known of his novels are Arnold, Az Atlas család ("The Atlas Family"). He died at Budapest on the 19th of November 1891.

CSOKONAI, MIHALY VITEZ (1772–1805), Hungarian poet, was born at Debreczen in 1773. Having been educated in his native town, he was appointed while still very young to the professorship of poetry there; but soon after he was deprived of the post on account of the immorality of his conduct. The remaining twelve years of his short life were passed in almost constant wretchedness, and he died in his native town, and in his mother's house, when only thirty-one years of age. Csokonai was a genial and original poet with something of the lyrical fire of Petőfi, and wrote a mock-heroic poem called Dorotya or the Triumph of the Ladies at the Carnival, two or three comedies of farces, and a number of love-poems. Most of his works have been published, with a life, by Schedel (1842–1847).

CSOMA DE KÖRÖS, ALEXANDER (c. 1790–1842), or, as the name is written in Hungarian, Köröszi Csoma Sámson, Hungarian traveler and philologist, born about 1790 at Körös in Transylvania, belonged to a noble family which had sunk into poverty. He was educated at Nagy-Éneyd and at Göttingen; and, in order to carry out the dream of his youth and discover the origin of his countrymen, he divided his attention between medicine and the Oriental languages. In 1820, having received from a friend the promise of an annuity of 100 florins (about £10) to support him during his travels, he set out for the East. He visited Egypt, and made his way to Tibet, where he spent four years in a Buddhist monastery studying the language and the Buddhist literature. To his intense disappointment he soon discovered that he could not thus obtain any assistance in his great object; but, having visited Bengal, his knowledge of Tibetan obtained him employment in the library of the Asiatic Society there, which possessed more than 2000 volumes in that language. Afterwards sent by the government, while he published a Tibetan-English dictionary and grammar (both of which appeared at Calcutta in 1834). He also contributed several articles on the Tibetan language and literature to the Journal of the Asiatic Society of Bengal, and he published an analysis of the Kah-Gyur, the most important of the Buddhist sacred books. Meanwhile his fame had reached his native country, and procured him a pension from the government, which, with characteristic devotion to learning, he devoted to the purchase of books for Indian libraries. He spent some time in Calcutta, studying Sanskrit and several other languages; but, early in 1842, he commenced his second attempt to discover the origin of the Hungarians, but he died at Darjiling on the 11th of April 1842. An oration was delivered in his honour before the Hungarian Academy by Éötvös, the novelist.

CTENOPHORA, in zoology, a class of jelly-fish which were briefly described by Professor T. H. Huxley in 1875 (see Actinzoa, Ency. Brit. 9th ed. vol. 1.) as united with what we now term Anthozaa to form the group Actinozoa; but little was known of the intimate structure of those remarkable and beautiful forms till the appearance in 1880 of C. Chun's Monograph of the Ctenophora occurring in the Bay of Naples. They may be defined as Coelentera which exhibit both a radial and bilateral symmetry of organs; with a stomodaeum; with a mesenchyma which is partly gelatinous but partly cellular; with eight meridional rows of vibratile paddles formed of long fused or matted cilia; lacking nematocysts (except in one genus). An example common on the British coasts is furnished by Hormíphora (Cydippe). In outward form this is an egg-shaped ball of clear jelly, having a mouth at the pointed (oral) pole, and a sense organ at the broader (aboral) pole. It possesses eight meridians (costae) of iridescent paddles in constant vibration, which run from near one pole towards the other; it has also two pendent feathery tentacles of considerable length, which can be retracted into pouches. The mouth leads into an ectodermal stomodaeum ("stomach"), and the latter into an endodermal funnel (infundibulum); these two are compressed in planes at right angles to one another, the sectional long axis of the stomodaeum lying in the so-called sagittal (stomodaeal or gastric) plane, that of the funnel in the transverse (tentacularr or funnel) plane. From the funnel, canals are given off in three directions: (a) a pair of paragastric (stomachal, or stomodaeal) canals run orally, parallel to the stomodaeum, and end blindly near the mouth; (b) a pair of perradial canals run in the transverse plane towards the equator of the animal; each of these becomes divided into two short canals at the base of the tentacle sheath which they supply, but has previously given off a pair of short interradial canals, which again bifurcate into two adradial canals; and these branches lie in the equatorial plane of the animal, but the eight adradial canals then open into eight meridional canals which run orally and aborally under the costae; (c) a pair of aboral vessels which run towards the sense-organ, each of which bifurcates; of the four vessels thus formed, two only open at the sides of the sense-organ, forming the so-called excretory apertures. These three sets of structures, with the funnel from which they rise, make up the endodermal coelenteron, or gastro-vascular system. The generative organs are endodermal by origin, borne at the sides of the meridional canals as indicated by the signs of $\Phi$. There exists a subepithelial plexus with nerve cells
and fibres, similar to that of jelly-fishes. The sense-organ of the aboral pole is complex, and lies under a dome of fused cilia shaped like an inverted bell-jar; it consists of an otolith, formed of numerous calcareous spheroids, which is supported on four plates of fused cilia termed balancers, but is otherwise free. The ciliated ectoderm below the organ is markedly thickened, and perhaps functionally represents a nerve-ganglion: from it eight ciliated furrows radiate outwards, two passing under each balancer as through an archway, and diverge each to the head of a meridinal costa. These ciliated furrows stain deeply with osmic acid, and nervous impulses are certainly transmitted along them. Locomotion is effected by strokes of the paddles in an aboral direction, driving the animal mouth forwards through the water: each paddle or comb (Gr. ∆τήνα, hence Ctenophora) consists of a plate of fused or matted cilia set transversely to the costa. The myoepithelial cells (formerly termed neuro-muscular cells), characteristic of other Coelentera, are not to be found in this group. On the other hand there are well-marked muscle fibres in definite layers, derived from special mesoblastic cells in the embryo, which are embedded in a jelly; these in their origin and arrangement are quite comparable to the mesoderm of Triploblastica, and, although the muscle-cells of some jelly-fish exhibit a somewhat similar condition, nothing so highly specialized as the mesenchyme of Ctenophora occurs in any other Coelenterate. The nematocysts being nearly absent from their group, their chief function is carried out by adhesive lasso-cells.

The Ctenophora are classified as follows:

Subclass i. Tentaculata, Order 1. Cydippidea, Hormiphora.
  2. Lobata, Desiphas.

The Tentaculata, as the name implies, may be recognized by the presence of tentacles of some sort. The Cydippidea are generally spherical or ovoid, with two long retrusible paddle tentacles; the meridinal and paragastric canals end blindly. An example of these has already been briefly described. The Lobata are of the same general type as the first Order, except for the presence of four circumanal auricles (processes of the subtransverse costae) and of a pair of sagittal outgrowths or lobes, on to which the subgastral costae are continued. All accessory tentacles lie in grooves, but there is no tentacular pouch; the meridinal vessels anastomose in the lobes. In the Cestoidea the body is compressed in the transverse plane, elongated in the sagittal plane, so as to become ribbon-like: the subgastric costae are greatly reduced, the subgastral costae extend along the oral edge of the riband. The subgastric canals lie immediately below their costae orally, but continuations of the subtransverse canals round down the middle of the riband, and at its end unite, not only with the subgastral but also with the paragastric canals which run along the oral edge of the riband. The tentacular bases and pouches are present, but there is no main tentacle as in Cydippidea; fine accessory tentacles lie in four grooves along the oral edge. The subclass Nuda have no tentacles of any kind; they are conical or ovoid, with a capacious stomodaeum like the cavity of a thimble. There is a coelenteric network formed by anastomoses of the meridinal and paragastric canals all over the body.

The embryology of Callianira has been worked out by E. Mechnikov. Segmentation is complete and unequal, producing macromeres and micromeres marked by differences in the size and in yolks of their contents. The micromeres give rise to the ectoderm; each of the sixteen macromeres, after budding off a small mesoblast cell, passes on as endoderm. A gastrula is established by a mixed process of embole and epibole. The mesoblast cells travel to the aboral pole of the embryo, and there form a cross-shaped mass, the arms of which lie in the sagittal and transverse planes (piraddi).

There can be but little question of the propriety of including Ctenophora among the Coelentera. The undivided coelenteron (gastro-vascular system) which constitutes the sole cavity of the body, the largely radial symmetry, the presence of endodermal generative organs on the coelenteric canals, the subepithelial nerve-plexus, the mesogloea-like matrix of the body—all these features indicate affinity to other Coelentera, but, as has been stated in the article under that title, the relation is by no means close. At what period the Ctenophora branched off from the line of descent, which culminated in the Hydromedusae and Scyphozoa of today, is not clear, but it is practically certain that they did so before the point of divergence of these two groups from one another. The peculiar sense-organ, the specialization of the cilia into paddles with the corresponding modifications of the coelenteron, the anatomy and position of the tentacles, and, above all, the character and mode of formation of the mesenchyme, separate them widely from other Coelentera.

The last-named character, however, combined with the discovery of two remarkable organisms, Coeloplana and Ctenoplana, has suggested affinity to the flatworms termed Turbellaria. Ctenoplana, the best known of these, has recently been redescribed by A. Willey (Quart. Journ. Micr. Sci. xxxix., 1896). It is flattened along the axis which unites sense-organ and mouth, so as to give it a dorsal (aboral) surface, and a ventral (oral) surface on which it frequently creeps. Its costae are very short, and retrusible; its two tentacles are pinnate and are also retrusible. Two crescentic rows of ciliated papillae lie in the transverse plane on each side of the sense-organ. The coelenteron exhibits six lobes, two of which Willey identifies with the stomodaeum of other Ctenophora; the other four give rise to a system of anastomosing canals such as are found in Berot and Polyclad Turbellaria. An aboral vessel embraces the sense-organ, but has no external opening. Ctenoplana is obviously a Ctenophoran flattened and of a creeping habit. Ctenoplana is of similar form and habit, with two Ctenophoran tentacles: it has no costae, but is uniformly ciliated. These two forms at least indicate a possible stepping-stone from Ctenophora to
CUBA

(Ed. M.)

CUBA (the aboriginal name), a republic, the largest and most populous of the West India Islands, included between the meridians of 74° 7' and 84° 57' W. longitude and (roughly) the parallels of 19° 48' and 23° 13' N. latitude. It divides the entrance to the Gulf of Mexico into two passages of nearly equal width,—the Strait of Florida, about 110 m. wide between Capes Hicacos in Cuba and Arenas in Florida (Key West being a little over 100 m. from Havana); and the Yucatan Channel, about 130 m. wide between Capes San Antonio and Catoche. On the N.E., E. and S.E., narrower channels separate it from the Bahamas, Haiti (50 m.) and Jamaica (85 m.). In 1908, by the opening of a railway along the Florida Keys, the time of passage by water between Cuba and the United States was reduced to a few hours.

The island is long and narrow, somewhat in the form of an irregular crescent, convex toward the N. It has a decided pitch to the S. Its length from Cape Mais to Cape San Antonio along a medial line is about 730 m.; its breadth, which averages about 50 m., ranges from a maximum of 160 m. to a minimum of about 22 m. The total area is estimated at 41,634 sq. m. without the surrounding keys and the Isle of Pines (area about 1180 sq. m.), and including these is approximately 44,164. The geography of the island is still very imperfectly known, and all figures are approximate only. The coast line, including larger bays, but excluding reefs, islets, keys and all minute sinuosities, is about 2500 m. in length. The N. littoral is characterized by bluffs, which grow higher and higher toward the east, rising to 600 ft. at Cape Mais. They are marked by distinct terraces. The southern coast near Cape Mais is low and sandy. From Guantánamo to Santiago it rises in high escarpments, and W. of Santiago, where the Sierra Maestra runs close to the sea, there is a very high abrupt shore. To the W. of Manzanillo it sinks again, and throughout most of the remaining distance to Cape San Antonio it is low, with a sandy or marshy littoral; at places sand hills fringe the shore; near Trinidad there are hills of considerable height; and the coast becomes high and rugged W. of Point Fisga, in the province of Pinar del Río. On both the N. and the S. side of the island there are long chains of islets and reefs and coral keys (of which it is estimated there are 1300), which limit access to probably half of the coast, and on the N. render navigation difficult and dangerous. On the S. they are covered with mangroves. A large part of the southern littoral is subject to overflow, and much more of it is permanently marshy. The Zapata Swamp near Cienfuegos is 600 sq. m. in area; other large swamps are the Majaguillar, E. of Cárdenas, and the Ciénaga del Buey, S. of the Cauto river. The Isle of Pines in its northern part is hilly and wooded; in its southern part, very low, level and rather barren; a tidal swamp almost cuts the island in two.

CTESIAS—CUBA

Turbellaria, that is to say, from diploblastic to triploblastic Metazoa. By themselves they would present no very weighty argument for this line of descent; from two-layered forms, but the coincidences which occur in the development of Ctenophora and Turbellaria,—the methods of segmentation and gastrulation, of the separation of the mesoblast cells, and of mesenchyme formation,—together with the marked similarity of the adult mesenchyme in the two groups, have led many to accept this pedigree. In his Monograph on the Polyclad Turbellaria of the Bay of Naples, A. Lang regards a Turbellarian, so to say, as a Ctenophora, in which the sensory pole has rotated forwards in the sagittal plane through 90° as regards the original oral-aboral axis, a rotation which actually occurs in the development of Thysanozoon (Miller's larva); and he sees, in the eight lappets of the preoral ciliated ring of such a larva, the rudiments of the costal plates. According to his view, a simple early Turbellarian larva, such as that of Stylocus, most nearly represents for us to-day that ancestor from which Ctenophora and Turbellaria are alike derived. For details of this brilliant theory, the reader is referred to the original monograph.

(CTESIAS, of Cnidus in Caria, Greek physician and historian, flourished in the 5th century B.C. In early life he was physician to Artaxerxes Memnon, whom he accompanied (401) on his expedition against his brother Cyrus the Younger. Ctesias was the author of treatises on rivers, and on the Persian revenues, of an account of India (which is of value as recording the beliefs of the Persians about India), and of a history of Assyria and Persia in 23 books, called Persica, written in opposition to Herodotus in the Ionic dialect, and professedly founded on the Persian royal archives. The first six books treated of the history of Assyria and Babylon to the foundation of the Persian empire; the remaining seventeen went down to the year 350. Of the two histories we possess abridgments by Phiotus, and fragments are preserved in Athenaeus, Plutarch and especially Diodorus Siculus, whose second book is mainly from Ctesias. About the work, the remainder of his Persica there has been much controversy, both in ancient and modern times. Being based upon Persian authorities, it was naturally looked upon with suspicion by the Greeks and censured as untrustworthy.

For an estimate of Ctesias as a historian see G. Rawlinson's Herodotus, i. 71-74; also the edition of the fragments of the Persica by J. Gilmore (1888, with introduction and notes and list of authorities).

CTESIPHON, a large village on the left bank of the Tigris, opposite to Seleucia, of which it formed a suburb, about 25 m. below Bagdad. It is first mentioned in the year 220 by Polybius v. 43. 4. When the Parthian Arsacids had conquered the lands east of the Euphrates in 129 B.C., they established their winter residence in Ctesiphon. They dared not stay in Seleucia, as this city, the most populous town of western Asia, always manifested a tendency to revolt, and they felt the necessity of a strong government and a strong feeling of independence, which made her incline to the west whenever a Roman army attacked the Parthians. The Arsacids were also afraid of destroying the wealth and commerce of Seleucia, if they entered with its large retinue of barbarian officials and soldiers (Strabo xvi. 743, Plin. vi. 122, cf. Joseph. Ant. xviii. 9, 2). From this time Ctesiphon increased in size, and many splendid buildings rose; it had the outward appearance of a large town, although it was by its constitution only a village. From A.D. 36-43 Seleucia was in rebellion against the Parthians till at last it was forced by King Vardanes to yield. It is very probable that Vardanes now tried to put Ctesiphon in its place; therefore he is called founder of Ctesiphon by Ammianus Marcellinus (xxii. 6, 23), where King Pacorus (78-110) is said to have increased its inhabitants and built its walls. Seleucia was destroyed by the Romans in A.D. 164. When Ardashir I. founded the Sassanian empire (226), and fixed his residence at Ctesiphon, he built up Seleucia again under the name of Veh-Ardashir. Later kings added other suburbs; Chosroes I. in 540 established the inhabitants of Antiochia in Syria, whom he had led into captivity, in a new city, "Chosrau-Antioch" (or "the Roman city") near his residence. Therefore the Arabs designate the whole complex of towns which lay together around Seleucia and Ctesiphon and formed the residence of the Sassanids by the name Madain, "the cities,"—their number is often given as seven. In the wars between the Roman and Persian empires, Ctesiphon was more than once besieged and plundered, thus by Odaenathus in 261, and by Carus in 283; Julian in 363 advanced to Ctesiphon, but was not able to take it (Amianus xxiv. 7). After the battle of Kadiysia (Qadisiya) Ctesiphon and the neighbouring towns were taken and plundered by the Arabs in 657, who brought home an immense amount of booty (see CALIPHATES). From then, these towns decayed before the increasing prosperity of the new Arab capitals Basra and Bagdad. The site is now only the ruins of one gigantic building of brick-work, called Takhti Khesra, "throne of Khusrau" (i.e. Chosroes). It is a great mound, 60 m. in diameter, and ornamented with pilasters, the remainder of the palace and the most splendid example of Sassanian architecture (see ARCHITECTURE, vol. ii. p. 558, for further details and illustration).
A remarkable feature of the Cuban coast is the number of excellent anchorages, roadsteads and harbours. On the N. shore, beginning at the W., Bahía Honda, Havana, Matanzas, Cardenas, Nuevitas and Nipe; and on the S. shore running westward Guantánamo, Santiago and Cienfuegos, are harbours of the first class, several of them among the best of the world. Mariel, Cabafias, Banes, Sagua la Grande and Baracoa on the N., and Maimi, Santa Cruz, Batanabo and Trinidad on the S. are also excellent ports or anchorages. The peculiar pouch-shape of almost all the harbours named (Matanzas being a marked exception) greatly increases their security and defensibility. These pouch harbours are probably "drowned" drainage basins. The number of small bays that can be utilized for coast trade traffic is extraordinary.

In popular language the different portions of the island are distinguished as the Vuelta Abajo ("lower turn"), W. of Havana; the Vuelta Arriba ("upper turn"), E. of Havana to Cienfuegos—Vuelta Abajo and Vuelta Arriba are also used colloquially at any point in the island to mean "east" and "west"—Las Cinco Villas—i.e. Villa Clara, Trinidad, Remedios, Cienfuegos and Sancti Spiritus—between Cienfuegos and Sancti Spiritus; and Tierra Adentro, referring to the region between Cienfuegos and Bayamo. These names are extremely common. The province and city of Puerto Príncipe are officially known as Camagüey, their original Indian name, which has practically supplanted the Spanish name in local usage.

Five topographic divisions of the island are fairly marked. Santiago (now Oriente) province is high and mountainous. Camagüey is characterized by rolling, open plains, slightly broken, especially in the W., by low mountains. The E. part of Santa Clara province is decidedly rough and broken. The W. part, with the provinces of Matanzas and Havana, is flat and rolling, with occasional hills a few hundred feet high. Finally, Pinar del Río is dominated by a prominent mountain range and by outlying piedmont hills and mesas. There are mountains in Cuba from one end of the island to the other, but they are not derived from any central mass and are not continuous. As just indicated there are three distinctively mountainous districts, various minor groups lying outside these. The three main systems are known in Cuba as the occidental, central and oriental. The first, the Organ mountains, in Pinar del Río, rises in a sandy, marshy region near Cape San Antonio. The crest runs near the N. shore, leaving various flankers spurs and foothills, and a coastal plain which at its greatest breadth on the S. is some 20 m. wide. The plain on the N. is narrower and higher. The southern slope is smooth, and abounds in creeks and rivers. The portion of the southern plain between the bays of Cortés and Majana is the most famous portion of the Vuelta Abajo tobacco region. The mountain range is capriciously broken at points, especially near Bejucal. The highest part is the Pan de Guajaibón, near Bahía Honda, at the W. end of the chain; its altitude has been variously estimated from 250 to 1950 ft. The central system has two wings, one approaching the N. coast, the other covering the island between Sancti Spiritus and Santa Clara. It comprehends a number of independent groups. The highest point, the Pico Poterrillo, is about 2900 ft. in altitude. The summits are generally well rounded, while the lower slopes are often steep. Frequent broad intervals of low upland or low level plain extend from sea to sea between and around the mountains. Near the coast runs a continuous belt of plantations, while grazing, tobacco and general farm lands cover the lower slopes of the hills, and virgin forests much of the uplands and mountains.

The oriental mountain region includes the province of Oriente and a portion of Camagüey. In extent, in altitude, in mass, in complexity and in geological interest, it is much the most important of the three systems. Almost all the mountains are very bold. They are imperfectly known. There are two main ranges, the Sierra Maestra, and a line of various groups along the N. shore. The former runs from Cape Santa Cruz eastward along the coast some 125 m. to beyond the river Baconao. The Sierra de Cobre, a part of the system in the vicinity of Santiago, has a general elevation of about 3000 ft. Monte Turquino, 5700–8370 ft. in altitude, is the highest peak of the island. Gran Piedra rises more than 5200 ft., the Ojo del Toro more than 3300, the Anvil de Baracoa is somewhat lower, and Pan de Matanzas is about 1267 ft. The western portions of the range rise abruptly from the ocean, forming a bold and beautiful coast. A multitude of ravines and gullies, filled with torrential streams or dry, according to the season of the year, and characterized by many beautiful cascades, seem the narrow coastal plain and the flanks of the mountains. The spurs of the central range are a highly intricate complex, covered with dense forests of superb woods. Many points are inaccessible, and the scenery is wild in the extreme. The mountains beyond Guantánamo are locally known by a variety of names, though topographically a continuation of the Sierra Maestra. The same is true of the chains that coalesce with these near Cape Maisí and diverge northwesterly along the N. coast of the island. The general character of this northern marginal system is much the same as that of the southern, save that the range is much less
Cuba

continuous. A dozen or more groups from Nipe in the E. to the coast N. of Camagüey in the W. are known only by individual names. The range near Baracoa is extremely wild and broken. The region between the lines of the two coastal systems is a much dissected plateau, imperfectly explored. The Cauto river, the only one flowing E. or W. and the largest of Cuba, flows through it westward to the southern coast near Manzanillo. The scenery in the oriental portion of the island is very beautiful, with wild mountains and tropical forests. In the central part there are extensive prairies. In the west there are swelling hills and gentle valleys, with the royal palm the dominating tree. The valley of the Yumurí, near Matanzas, a small circular basin crossed by a river that issues through a glen to the sea, is perhaps the most beautiful in Cuba.

A very peculiar feature of Cuba is the abundance of caverns in the limestone deposits that underlie much of the island's surface. The caves of Cotilla near Havana, of Bellamar near Matanzas, of Monte Líbano near Guantánamo, and those of San Juan de los Remedios, are the best known, but there are scores of others. Many streams are "disappearing," part of their course being through underground tunnels. Thus the Río San Antonio suddenly disappears near San Antonio de los Baños; the cascades of the Jatibónico del Norte disappear and reappear in a surprising manner; the Moa cascade (near Guantánamo) drops 300 ft. into a cavern and its waters later resurface from the earth; the Jojo river disappears in a great "sink" and later issues with violent current at the edge of the sea. The springs of fresh water that bubble up among the keys of the S. coast are also supposedly the outlets of underground streams.

The number of rivers is very great, but almost without exception their courses are normal to the coast, and they are so short as to be of but slight importance. The Cauto river in Oriente province is exceptional; it is 250 m. long, and navigable by small vessels for about 75 m. Inside the bar at its mouth (formed by a storm in 1616) ships of 200 tons can still ascend to Cauto. In Camagüey province the Jatibónico del Sur; in Oriente the Salado, a branch of the Cauto; in Santa Clara the Sagua la Grande (which is navigable for some 20 m. and has an important traffic) and the Damuji; in Matanzas, the Canimar; and Pinar del Río the Cuyaguejí, are important streams. The water-parting in the four central provinces is very indefinite. There are few river valleys that are noteworthy—those of the Yumurí, the Trinidad and the Guines. At Guantánamo and Trinidad are other valleys, and between Mariel and Havana is the fine valley of Ariguana. Of lakes, there are a few on the coast, and a very few in the mountains. The finest is Lake Ariguana, near Havana, 6 sq. m. in area. Of the almost innumerable river cascades, those of the Sierra Maestra Mountains, and in particular the Moa cascade, have already been mentioned. The Guaná cascade in Oriente province and the Hanabanilla Fall near Cienfuegos (each more than 300 ft. high), the Rosario Fall in Pinar del Río, and the Almendares cascade near Havana, may also be mentioned.

Geology. One of the most interesting features of Cuba is the formation of metamorphic and igneous rocks, which appear in the Sierra Maestra and are exposed in other parts of the island wherever the comparatively thin covering of later beds has been worn away. A more or less continuous belt of metamorphic rocks, beginning 100 miles to the S. of Havana, extends for 1000 miles to the E. of Santiago de los Baños, although it nowhere attains to any great height. It is in this band that the greater part of the mineral wealth of Cuba is situated. These ancient rocks have hitherto yielded no fossils and their age is therefore uncertain, but they are probably pre-Cretaceous at least. The most prominent formation in this group is the Rudistes, which have been found in several parts of the island (Santiago de los Baños, Santa Clara province, &c.). At the base there is an arboleo, composed largely of fragments of serpentinite and granite derived by metamorphism. A vast deposit of limestone, lying on the Rudistes, has been found in the Santa Clara province, bituminous plant-bearing beds occur beneath the Tertiary limestones, and at Baracoa a Radiolarian earth occupies a similar position. The latter, like the similar deposits in the coast of Canada, is supposed to be of much greater age, possibly of Oligocene age. It is the Tertiary limestones which form the predominant feature in the geology of Cuba. Although they do not exceed 1000 ft. in thickness, they probably at one time covered the whole island except the summits of the Sierra Maestra, where they have been observed, resting upon the older rocks, up to a height of 2500 ft. They contain corals, but not coral reefs. The shells which have been found in them indicate that they belong for the most part to the Oligocene period. They are frequently very much disturbed and often strongly folded. Around the coast there is a raised shelf of limestone which was undoubtedly a coral reef. But it is of recent date and does not approach the great elevation of the great coral reef of the coast of America.

Minerals are fairly abundant in number, but few are present in sufficient quantity to be industrially important. Traditions of gold and silver, dating from the time of the Spanish conquest, still endure, though the only minerals actually found to be of value are copper and coal. The latter is mainly in well-marked fracture planes in serpentinite; the ore is pyrotubite, with or without chalcopyrite. Manganese occurs especially along the coast between Santiago and Manzanillo; the best ores run above 30% of MnO and are found in quantities sufficient to found the industry here, though the ore is not in a form to exist, but probably not in commercially available quantities. Bituminous products of every grade, from clear translucent oils resembling petroleum and refined naphtha, to lignite-like substances, are obtainable. Some quantities of lignite and coal have been worked in a few places, but the deposits are insufficient or too far from the railways to be worked. The Abacuca de la Vega, near Trinidad, has moderate deposits of coal; and sandstones occur on the N. coast of Pinar del Río province. Clays of all qualities and colours abound. Mineral waters, though not yet important in trade, are extremely abundant, and a score of mineral springs and health resorts. Those near San Diego, Guanabacoa and Santa María del Rosario (near Havana) and Madruga (near Guines) are the best known.

The soil of the island is almost wholly of modern formation, mainly alluvial, with superficial limestones as another prominent feature. In the original formation of the island volcanic disturbances and coral growth played some part; but there are only very slight superficial evidences in the island of former volcanic activity. Note- worthy are the iron ore deposits of the Caribe coast. The Iturralde, or Cobre, is the richest in Oriente province. Those of 1776, 1842 and 1852 were particularly destructive, and of earlier ones those of 1551 and 1564 at Bayamo, and of 1378 and 1378 at Santiago. Every year there are seismic disturbances of lesser extent, and the fact that they occur in all parts of the island, in 1880 affecting the entire western end. Notable seismic disturbances in Cuba have coincided with similar activity in Central America so often as to make seismological association probable.

Flora.—The tropical heat and humidity of Cuba make possible a flora of splendid richness. All the characteristic species of the West Indies, the Central American and Mexican and southern Mexican and southern Central American vegetation, and lastly the genus of the tropical forest of the Americas, are embraced in it. As many as 3350 native flowering species were catalogued in 1876. The total number of species of the island flora was estimated in 1892 by a writer in the Revista Cubana (vol. xxxviii, p. 264) to be between 4000 and 5000. This number had then been gathered into a herbarium, and all parts of the island had not then been explored. It was estimated officially in 1904 that the wooded lands of the island comprised 3,628,434 acres, or about 15% of the total area. The beautiful cedro (Cedrela odorata), the wood of which is used for furniture, is one of the most valuable commercial products of Cuba. The beautiful cedro (Cedrela odorata) is also put to various uses. The mango is planted with the royal palm along the avenues of the plantations. The beautiful cedro (Cedrela odorata) is also put to various uses.
CUBA
remarkable for the magnificent purple flowers that cover
Utilitarian
are also noteworthy.
trees and plants are legion. There are at least forty choice cabinet
and building woods. Of these, ebonies, mahogany (for the bird's-eye
variety such enormous prices are paid as $1200 to $1800 per.thousand
board-feet), culla (or cuya, Bumelia retusa), cocullo (cocuyo, Bumelia

velatina)
it.

is

The tamarind and banyan

nigra), ocuje (Callophyllum viticifolia, Ornitrophis occidentalis, O.
coniinia), jigiie (jique, Lysiloma sabicu), mahagua {Hibiscus tiliaceus),
granadillo (Brya ebenus), icaquillo (Licania incania) and ag.ua-baria

(Cordia gerascanthes) are perhaps the most beautiful. Other woods,
beautiful and precious, include guayacan (Guaiacum sanctum), baria
(varia, Cordia gerascanthoides)
the fragrant, hard-wood Spanish
elm the quiebra-hacha (Copaijera hymenofolia)
which three
are of wonderful lasting qualities; the jiqui (Malpighia obovata),
acana (Achras disecta, Bassia albescens),- caigaran (or caguairan,
Hymenaea floribunda), and the dagame {Calicophyllum candidissimum), which four, like the culla, are all wonderfully resistant to
humidity; the caimatillo (Chrysophyllum oliviforme), the yaya (or
yayajabico, yayabito: Erylhalis fructicosa, Bocagea virgata, Guateria
virgata, A simina Blaini)
a magnificent construction wood the
maboa (Cameraria latifolia) and the jocuma (jocum: Sideroxylon
mastichodendron, Bumelia saticifolia) all of individual beauties and
qualities.
Many species are rich in gums and resins the calambac,
mastic, copal, cedar, &c. Many others are oleaginous, among them,
peanuts, sun-flowers, the bene seed (sesame), corozo, almond and
palmachristi. Others (in addition to some already mentioned) are
medicinal; as the palms, calabash, manchineel, pepper, fustic and
a long list of cathartics, caustics, emetics, astringents, febrifuges,
vermifuges, diuretics and tonics.
Then, too, there are Various
dyewoods; rosewood, logwood (or campeachy wood), indigo,
manajii (Garcinia Morella), Brazil-wood and saffron. Textile plants
are extremely common. The majagua tree grows as high as 40 ft.
from its bark is made cordage of the finest quality, which is scarcely
affected by the atmosphere. Strong, fine, glossy fibres are yielded
by the exotic ramie (Boehmeria nivea), whose fibre, like that of the
majagua, is almost incorruptible; by themaya or rat-pineapple
(Brbmelia Pinguin), and by the daquilla (or daiguiya Lagetta
lintearia, L. valenzuelana) which like the maya yields a brilliant,
flexible product like silk; stronger cordage by the corojo palms,
and various henequen plants, native and exotic (especially Agave
americana, A. Cubensis); and various plantains, the exotic San-\
sevieria guineensis, okra, jute, Laportea, various lianas, and a great
variety of reeds, supply varied textile materials of the best quality.
The yucca is a source of starch. For building and miscellaneous
purposes, in addition to the rare woods above named, there are
cedars (used in great quantities for cigar boxes) the pine, found
only in the W., where it gives its name to. the Isle of Pines and the
province of Pinar del Rio various palms oaks of varying hardness
and colour, &c. The number of alimentary plants is extremely great.
Among economic plants should be mentioned the coffee, cacao,

more than three can be marketed, unless

locally, as the

product

deteriorates. The better (" purple ") varieties are mainly consumed
in the island, and the smaller and less juicy " white " varieties

exported.

The tamarind

is

everywhere.

Bananas are grown par-

ticularly in the region about Nipe, Gibara and Baracoa, whence
they are exported in large quantities, though there is a tendency
to lessen their culture in these parts in favour of sugar. Mangoes,
though exotic, are extremely common, and in the E. grow wild in the
forests.
They are the favourite fruit of the negroes. Oranges are
little cultivated, although they offer apparently almost unlimited
possibilities; their culture decreased steadily after 1880, but after

about 1900 was again greatly extended. Lemons yield continuously
through the year, but like oranges, not much has yet been done
with them commercially. Pomegranates are as universally Used in
Cuba as apples in the United. States. Figs and grapes degenerate in
Cuba. Dates grow better, but nothing has been done with them.
The coco- nut palm is most abundant in the vicinity of Baracoa.
Among the common fruits are various anonas the custard apple
(Anonacherimolia), sweet-sop (A. squamosa), sour-sop (A. muricala),
mamon (A. reticulata), and others, the star-apple (Chrysophyllum
cainito, C. pomiferum), rose-apple (Eugenia jambos), pawpaw, the
sapodilla (Sapota achras), the caniste {Sapota Elongata), jagua
(Genipa americana), alligator pear (Per sea gratissimd), the yellow
mammee (Mammea americana) and so-called '*' red mammee
:

limes.

Fauna. The fauna of Cuba, like the flora, is still imperfectly
known. Collectively it shows long isolation from the other Antilles.
Only two land mammals are known to be indigenous. One is the
hutia (agouti) or Cuban rat, of which three species are known
(Capromys Fournieri, C. melanurus- and C. Poey). It lives in the

597

most solitary woods, especially in the eastern hills. The other is
a peculiar insectivore (Solenodon paradoxus), the only other representatives of whose family are found in Madagascar. Various animals,
apparently indigenous, that are described by the early historians
of the conquest, have disappeared.
An Antillean rabbit is very
abundant.
Bats in prodigious numbers, and some of them of
extraordinary size, inhabit the many caves of the island more than
twenty species are known. Rats and mice, especially the guayabita
(Mus musculus), an extremely destructive rodent, are very abundant.
The manatee, or sea-cow, frequents the mouths of rivers, the sargasso
drifts, and the regions of submarine fresh-water springs off the coast.
Horses, asses, cows, deer, sheep, goats, swine, cats and dogs were
introduced by the early Spaniards. The last three are common in
a wild state. Deer are not native, and are very rare a few live in
;

;

the swamps.
Of birds there are more than 200 indigenous species, it is said,
and migratory species are also numerous. Waders are represented
by more than fifty species. Vultures are represented by only one
species, the turkey buzzard, which is the universal scavenger of the
fields, and until recent years even of the cities, and has always
been protected by custom and, the Laws of the Indies. Falcons
are represented by a score of species, at least, several of them nocturnal.
Kestrels are common.
The gallinaceous order is rich in
Columbidae.
Trumpeters are notably represented, and climbers
still more so.
Among the latter are species of curious habits and
remarkable colouring. Woodpeckers (Coloptes auratus), macaws,
parrakeets and other small parrots, and trogons, these last of beautifully resplendent plumage, deserve particular mention. The Cuban
mocking-bird is a wonderful songster. Of humming-birds there
are said to be sixty species, probably only one indigenous. Of the
other birds mere mention may be made of the wild pigeon, raven,
indigo-bird, English lady-bird and linnet.
Reptiles are numerous. Many tortoises are notable. The crocodile and cayman occur in the swampy littoral of the south.
Of
lizards the iguana (Cyclura caudata) is noteworthy.
Chameleons
are common. Snakes are not numerous, and it is said that none is
poisonous or vicious. There is one enormous boa, the maja (Epicrates angulifer), which feeds on pigs, goats and the like, but does

not molest man.
Fishes are present in even greater variety than birds.
Felipa
Poey, in his Ictiologia Cubana, listed 782 species of fish and crustaceans, of which 105 were doubtful; but more than one-half of the
remainder were first described by Poey. The fish of Cuban waters are
remarkable for their metallic colourings'. The largest species are
found off the northern coast. Food fishes are relatively not abundant,
presumably because the deep sea escarpments of the N. are unfavourable to their life. Shell fish are unimportant. Two species
of blind fish, of extreme scientific interest, are found 'in the caves of
the island. Of the " percoideos " there are many genera. Among
the most important are the robalo (Labrax), an exquisite food fish,
the tunny, eel, Spanish sardine and mangua. Of the sharks the
genus Squalus is represented by individuals that grow to a length of
26 to 30 ft. The hammer-head attains a weight at times of 600 lb.
The saw-fish is common. Of fresh-water fish the lisa, dogro, guayacon and viajocos (Chromis fuscomaculalus) are possibly the most

noteworthy.
Molluscs are extraordinarily numerous and many, both of water
and land, are rarities among their kind for size and richness of colour.
Of crustaceans, land-crabs are remarkable for size and number.
Arachnids are prodigiously numerous. Insect life is abundant and
beautiful.
The bite of the scorpion and of the numerous spiders
produces no serious effects. The nigua, the Cuban jigger, is a pest of
serious consequence, and the mal de nigua (jigger sickness) sometimes causes the death of lower animals and men. Sand-flies and
biting gnats are lesser nuisances. Lepidoptera are very brilliant in
;

colouring.
The cucujo or Cuban firefly (Pyrophorus noctilucus)
gives out so strong a light that a few of them serve effectively as
a lantern. The Stegomyia mosquito, is the agent of yellow fever
inoculation. Sponges grow in great variety.
Climate.
The climate of Cuba is tropical and distinctively
insular in characteristics of humidity, equability and high mean
temperature. There are two distinct seasons: a " dry " season
from November to April, and a hotter, " wet " season. About

—

two-thirds of the total precipitation falls in the latter.
Droughts,
extensive in area and in duration, are by no means uncommon.
At Havana the mean temperature is about 76° F with extreme

monthly

oscillations ranging on the average from 6° to 12° F.
months, and with a range between the means of the
and warmest months of io° (70 to 8o°); temperatures

for different

coldest

below 50° or above go° being rare. The mean rainfall at Havana
is about 40-6 in. (sometimes over 80), and the mean absolute
huniidity of different months ranges from 70 to 80%.
These
figures represent fairly well the conditions of much of the northern
coast.
In the N.E. the rainfall is much greater. The equability

of heat

throughout the day

noon sea

breezes.

The

is masked and relieved by the aftertrades are steady through the year, and


in the dry season the western part of the island enjoys cool "nortners." Despite this the interior is somewhat cooler than the coast, and in the uplands frost is not uncommon. The south-west littoral is also (except in sheltered points such as Santiago, which is one of the hottest cities of the island) somewhat cooler than the northern.

More than eight or ten years rarely pass without tornadoes or hurricanes of local severity at least. Notably destructive ones occurred in 1768, 1774, 1842, 1844, 1846, 1856, 1870, 1876, 1883 and 1894. Those of 1842 and 1844 caused extreme distress in the island. In 1846, 300 vessels and 2000 houses were destroyed at Havana; in 1896 the banana groves of the N.E. coast were ruined and the banana industry prostrated; and in 1906 Havana suffered damage. The autumn months, particularly October and November, are those in which such storms most frequently occur.

Health.—Convincing evidence is offered by the qualities of the Spanish race in Cuba that white men of temperate lands can be perfectly acclimatized in this tropical island. As for diseases, some common to Cuba and Europe are more frequent or severe in the island, others rarer or milder. There are the usual malarial, bilious and intermittent fevers, and fever, stomach and intestinal complaints not infrequent in tropical countries; but unhygienic living is, in Cuba as elsewhere, mainly responsible for their existence. Yellow fever (which first appeared in Cuba in 1647) was long the only epidemic disease, Havana being an endemic focus. Aside from the recurrent loss of life, the pecuniary loss from such epidemics was enormous, and the interference with commerce and social intercourse with other countries extremely vexatious.

The Cuban coast was uninterrupted fully of infection, and with the danger of an outbreak in each year was never absent, until the work of the United States army in 1901-1902 conclusively proved that this disease, though ineradicable by the most extreme sanitary measures, based on the accepted theory of its origin as a filth-disease, could be eradicated entirely by removing the possibility of inoculation by the *Stegomyia* mosquito. Since then yellow fever has ceased to be a scourge in Cuba. Small-pox was the cause of a greater mortality than yellow fever even before the means of combating the latter had been ascertained. The remarkable sanitary work begun during the American occupation and continued by the republic of Cuba, has shown that the ravages of this and other diseases can be greatly diminished. As in the case of yellow fever, it is necessary to admit that but seemingly only slightly contagious. Consumption is very prevalent.

Agriculture.—Soils are of four classes: calcareous-ferruginous, alluvial, argillos and silicious. Calcareous lands are predominant, especially in the uplands. Deep residual clay soils derived from underlying limestones, and coloured red or black according to the predominance of oxides of iron or vegetable detritus, characterize the plains. A red-brown soil known as "mulato" or tawny is perhaps the best fitted for general cultivation. Tobacco is most generally cultivated on loose red soils, which are rich in clays and silicates; and sugar-cane preferably on the black and mulato soils; but in general, contrary to prevalent suppositions, colour is no test of quality and not a very valuable guide in the setting of crops. Almost without exception the lands throughout the island are of extreme fertility. The lowlands about Cienfuegos, Trinidad, Mariel and Matanzas are noted for their richness. The census of 1899 showed that farm lands occupied three-tenths of the total area; the cultivated area being one-tenth of the farms or 5% of the whole. At the end of 1905 it was officially estimated that 16% of the total area was under crop. The most cultivated crop, which is cassava, occupies an area of 2,000,000 acres, of which about 1,000,000 acres is under cultivation. The next in order of importance is the cultivation of sugar, which is carried on mainly in the provinces of Havana, Matanzas and Camagüey. The average size of a farm in 1899 was 14 acres. More than 85% of all cultivated lands were then occupied by whites; and somewhat more than one-half (56-6%) of all occupiers were renters. Holdings of more than 32 acres constituted only 7% of the total. As regards crops, 47% of the cultivated area was given over to sugar, 11% to sweet potatoes, 9% to tobacco and almost 9% to bananas.

But owing to the disturbed conditions created by the war it is probable that these figures by no means represent normal conditions. The actual sugar crop of 1899-1900, for example, was not a quarter of that of 1894. With the establishment of peace in 1898 and the influx of American and other capital and of a heavy immigration, great changes took place in agriculture as in other industrial conditions.

Sugar has been the dominant crop since the end of the 18th century. Before the Civil War of 1865-1868 the capital invested in sugar estates was greater by half than that represented by tobacco and coffee plantations, live-stock ranches and other farms. Since that time fruit and live-stock interests have increased. The dependence of the island on one crop has been an artificial economic condition often of grave momentary danger to prosperity; but generally speaking, the progress of the industry has been steady. The competition of the sugar-beet has been felt severely. During and after the war of 1868-1878, when many Cuban estates were confiscated, many families emigrated, and many others were ruined, the ownership of plantations largely passed from the hands of Cubans to Spaniards. Under the conditions of free labour, the development of sugar abroad, the improvement of machinery both of cane and beet, and beet crops in countries other than Russia, the beet and the fall of prices, it was impossible for the Cuban industry to survive without radical betterment of methods. About 1885 began an immense development of centralization (the tendency having been evident many years before this). Plantations have increased greatly in size (and also diminished in number), greater capital is involved, bagasse furnaces have been introduced, double grinding mills have increased by more than a half the yield of juice from a given weight of cane, and extractive operations instead of being carried on at all plantations have been (since 1880) concentrated in comparatively few "centrals" (168 in Feb. 1908). Three-fourths of all are in the jurisdictions of Cienfuegos, Cárdenas, Havana, Matanzas and Sagua la Grande, which are the great sugar centres of the island (three-fourths of the crop coming from Matanzas and Santa Clara provinces). Caibarién, Guantánamo and Manzanillo are next in importance. A comparatively low cost of labour, the fact that labour is not, as in the days of slavery, that of uneducated blacks but of intelligent free labourers, the centralized organization and modern methods that prevail on the plantations, the remarkable fertility of the soil (which yields 6 or 7 crops on good soil and with good management without replanting), and the proximity of the United States, in whose markets Cuba disposes of almost all her crop, have long enabled her to distance her smaller West Indian rivals and to compete with the bounty-fed beet. The methods of cultivation, however, are still distinctly extensive, and the returns are much less than they would be (and in some other cane countries are) under more intensive and scientific methods of cultivation. Indeed, conditions were relatively primitive so late as 1880, if compared with those of other sugar-producing countries. More than four-fifths of the total area sown to cane in the island is in the three provinces of Santa Clara, Matanzas and Oriente (formerly Santiago), the former two representing two-thirds of the area and three-fourths of the crop. The majority of the sugar estates are of an area less than 3000 acres, and the most common area is between 1500 and 2000 acres; but the extremes range from a very small size to 60,000 acres. Only a part of the great estates is ever planted in any one season. The most profitable unit is calculated to be a daily consumption of 1000 tons of cane, or 150,000 in a grinding season of 100 days, which yields 6 or 7 crops on good soil above 6000 acres. In the season of 1905-1906, which may be taken as typical, 179 estates, with a planted area of 431,056 acres, produced 11,576,137 tons of cane, and yields—in addition to alcohol, brandy and molasses—1,089,814 tons of sugar. Of this amount 416,862 tons were produced by 24 estates yielding more than 11,000 tons each, including one (planting 28,550 acres) that yielded 33,609, and 4 others more than 22,000 tons each. The production of the island from 1850 to 1868 averaged 469,934 tons yearly, rising from 223,145 to 740,000; from 1869 to 1886
the war of 1868–1878 the production amounted to about 25,000,000 lb yearly. The war of 1895–1898 still further diminished the vitality of the industry. In 1907 the crop was 6,595,700 lb. The berries are of fine quality, and despite the competition of Brazil there is no (agricultural) reason why the home market at least should not be supplied from Cuban estates.

Of other agricultural crops those of fruits are of greatest importance—bananas (which are planted about once in three years), pineapples (planted about once in five years), coco-nuts, oranges, etc. The coco-nut industry has long been largely confined to the region about Baracoa, owing to the ruin of the trees elsewhere by a banana-like disease. But thoroughly understood, which, appearing finally near Baracoa, threatened by 1908 to destroy the industry there as well. Yams and sweet-potatoes, yuccas, malangas, cacao, rice—which is one of the most important foods of the people, but which is not yet badly—and Indigo, which grows everywhere and yields two crops yearly, may be mentioned also. In very recent years gardening has become an interest of importance, particularly in the province of Pinar del Río. Save on the coffee, tobacco and sugar plantations, where competition in large markets has compelled the adoption of adequate modern methods, agriculture in Cuba is still very primitive. The wooden ploughstick, for instance—taking the country as a whole—has never been displaced. A central agricultural experiment station (founded 1904) is maintained by the government at Santiago de las Vegas; but there is no agricultural college, nor any special school for the scientific teaching and improvement of sugar and tobacco farming or manufacture.

Stock-breeding is a highly important interest. It was the all-important one in the early history of the island, down to about the latter part of the 18th century. Grasses grow luxuriantly, and the savannahs of central Cuba are, in this respect, excellent cattle ranges. The droughts to which the island is recurrently subject are, however, a not unimportant drawback to the industry; and though the best ranges, under favourable conditions, are luxuriant, nevertheless the pastures of the island are in general mediocre. Practically nothing has yet been done in the study of native grasses and the introduction of exotic species. The possibilities of the stock interest have as yet by no means been realized. The civil wars were probably more disastrous to it than to any other agricultural interest of the country. It has been estimated that from 90 to 95% of all horses, neat cattle and hogs in the entire island were lost in the war years of 1895–1898. In the decade after 1898 particularly great progress was made in the raising of live-stock. On fishing and sponge industries are important. Batabano and Caibarién are centres of the sponge fisheries.

Manufactures.—The manufacturing industries of Cuba have never been more than insignificant, as compared with what they might be. In 1907 48.7% of all wage-earners were employed in agriculture, fishing and mining, 16.3 in manufactures, and 17.7 in trade and transportation. Such manufactures as are of any consequence are mostly connected with the sugar and tobacco industries. Forest resources have been but slightly touched (more so since the end of Spanish rule) except mahogany, which goes to the United States, and cedar, which is used to box the tobacco products of the island, much going also to the United States. The value of forest products in 1901–1902 amounted to $320,528. There are some tanneries, some preparation of preserves and other fruit products, and some old handicraft industries like the making of hats; but these have been of comparatively scant importance. Despite natural advantages for all meat industries, canned meats have generally been imported. The leading manufactures are cigars and cigarettes, sugar, rum and whisky. The tobacco industries are very largely concentrated in Havana, and there are factories in Santiago de las Vegas and Bejucal. The yearly output of cigars was largely estimated in 1908 at about 300,000,000, but this is probably an overestimate. An exhibition of 1904–1906 the yearly average output to the United States was 216,254,300 lb of leaf and 14,203,571 packages of cigarettes. The sugar industry is not similarly centralized. With the improvement of methods the old partially refined grades (moscobados) have disappeared.

Mining.—Mining is of very considerable importance. The Cobre copper mines near Santiago were once the greatest producers of the world. They were worked from 1524 until about 1730, when they were abandoned for almost a century, after which they were reopened and greatly developed. In 1828–1840 about two million dollars' worth of ore was shipped yearly.

Coffee.

The first attestation of the settlement in eastern Cuba, late in the 18th century, of French refugee immigrants from San Domingo. Some "cafe-tales" were established by the newcomers near Havana, but the industry has always been almost exclusively one of Oriente province; with Santa Clara as a much smaller producer. Before

Other countries taking only 27,462 long tons out of a total of 5,719,777 in the seven fiscal years 1899–1900 to 1905–1906.

Tobacco. Tobacco of Cuba comes from Pinar del Rio province; the rest mainly from the provinces of Havana and Santa Clara,—the description de partido being applied to the leaf not produced in Havana and Pinar del Rio provinces, and sometimes to all produced outside the nuevo tabaco. They do not exist, including the yellow sort, as a white. The southern slopes of the Oriental Mountains between the Honda river and Mantua; bananas are cultivated with the tobacco. "Vegas"—(tobacco fields) of especially good repute are also found near Trinidad, Remedios, Yara, Mayarí and Vicana. The tobacco industry has been uniformly prosperous, except when crippled by the destruction of war in 1868–1878 and 1895–1898. Even in the time of slavery tobacco was generally a white-man's crop; for it requires intelligent labour and intensive care. In recent years the growth of the leaf under cloth tents has greatly increased, as it has been abundantly proved that the product thus secured is much more valuable—lighter in colour and weight, finer in texture, with an increased proportion of wrapper leaves, and more external qualities, and with lesser amounts of cellulose, nicotine, gums and resins. In these respects the finest Cuban tobacco crops, produced in the sun, hardly rival the finest Sumatra product; but produced under cloth-tent they do. "Cuban tobacco" does not mean to-day, as a commercial fact, what the words imply; for the original Nicotiana Tabacum, variety havanensis, can produce it only in Australia. Tobacco, however, was introduced to Cuba by Pinar del Rio. After the Ten Years' War seed of Mexican and United States tobaccos was in great demand to re-seed the ruined vegas, and was introduced in great quantities; and although by a later law the destruction of these exotic species was ordered, that destruction was in fact quite impossible. "Lust grows forer and coarser than the genuine old-time Cuban... Mexican tobaccos (Nicotiana Tabacum, variety macrophyllum) are to-day predominant in a large part of Cuban vegas... Ordinary commercial Cuban seed of to-day is largely, and often altogether, Mexican tobacco." Though improved in the Cuban environment, the foreign tobaccos introduced after the Ten Years' War did not lose their exotic character, but prevailed over the indigenous forms: "Tobaccos with exactly the character of the introduced types are now the prevalent forms" (quotation from Bulletin of the Estación Central Agronómica, Feb. 1908). In the markets of the world Cuban tobacco has always suffered less competition than Cuban sugar, and still less has been done than in the case of sugar cane in the study of methods of cultivation, which in several respects are far behind those of the great tobacco-culturing countries. The crop of 1907 was 201,512 bales (100,932,400 lb Sp.).

Coffee-raising was once a flourishing and very promising industry. It first attained prominence with the settlement in eastern Cuba, late in the 18th century, of French refugee immigrants from San Domingo. Some "cafe-tales" were established by the newcomers near Havana, but the industry has always been almost exclusively one of Oriente province; with Santa Clara as a much smaller producer. Before...
to the United States alone. After 1868 the mines were again abandoned and flooded, the mining property being ruined during the civil war. Finally, after 1906 they again became prosperous producers. The "Cobre" mine is only the most famous and productive of the numerous copper properties. The copper output has greatly increased since 1890, and is of slight importance in mineral exports. Iron and manganese have, on the contrary, been greatly developed in the same period. Iron is now the most important mineral product. The iron ores are even more accessible than the famous ones of the Lake Superior region in the United States. No shafts or tunnels are necessary except for exploration; the mining consists entirely in open-cut and terrace work. The cost of exploitation is accordingly slight. Daiquirí, near Santiago, and mines near Nipe, on the north coast, are the chief centres of production. Nearly the entire product goes to the United States. The first exports from the Daiquirí district were made by an American company in 1884; the Nipe (Cagimaya) mines became prominent in promise in 1906. The shipments from Oriente province from 1884 to 1901 aggregated 5,553,847 long tons, almost all going to the United States (which is true of other mineral products also). After 1900 production was greatly increased and by 1906 had come to exceed half a million tons annually. There are small mines in Santander and Camagüey provinces and one near La Maya, not far from El Cobre in Oriente. The traditions as to gold and silver have already been referred to. Evidences of ancient workings remain near Holguín and Gibara, and it is possible that some of these workings are still exploitable. Mining for the precious metals ceased at a very early date, after rich discoveries were made on the continent. Bituminous products, though, as already stated, widely distributed, are not as yet much developed. The most promising deposits and the most important workings are in Matanzas and Santa Clara provinces. Petroleum has been used to some extent both as a fuel and as an illuminant. Small amounts of asphalt have been sent to the United States. Locally, asphalts are used as gas enrichers. Garamite and glance-pitch are common, and are exported for use in varnish and paint manufactures. The commercial product of stones, brick and cement is of rapidly increasing importance. The foundation of the island is in many places almost pure carbonate of lime, and there are numerous small limekilns. The product is used to bleach sugar, as well as for construction and disinfection purposes. The number of small brick plants is legion, almost all very primitive.

Commerce.—Commerce (resting largely upon specialized agriculture) is vastly more prominent as than merely manufacturing and mining in the island's economy. The leading articles of export are sugar, tobacco and fruit products; of import, textiles, foodstuffs, lumber and wood products, and machinery. Sugar and tobacco products together represent seven-eighths (in 1905-1907 respectively 60-3 and 27-3%) of the normal annual exports. In the quinquennial period 1890-1894 (immediately preceding the War of Independence) the average yearly commerce of the island and out was $86,875,663 with the United States; and $28,161,726 with Spain. During the American military occupation of the island in 1899-1902, of the total imports 45-9% were from the United States, 14 from other American countries, 15 from Spain, 14 from the United Kingdom, 6 from France and 4 from Germany; of the exports the corresponding percentages for the same countries were 70-7, 2, 3, 10, 4 and 7. No special favours were enjoyed by the United States in this period, and about the same percentages prevailed in the years following. The total commercial movement of the two countries in 1902 exceeded $177,882,640 (for the whole fiscal years 1902-1903 to 1906-1907, $185,867,020 annually, and of this the share of the United States was $108,431,000 yearly, representing 45-8% of all imports and 81-9% of all exports. The proportion of imports taken from the United States is greatest in foodstuffs, metals and metal manufactures, timber and furniture, mineral oils and lard. The trade of the United States with the island was as great in 1900-1907 as with Mexico and all the other West Indies combined; as great as its trade with Spain, Portugal and Italy combined; and almost as great as its trade with China and Japan.

Communications.—Poor means of communication have always been a great handicap to the industries of the island. The first railroad in Cuba (and the first in Spanish lands) was opened from Havana to Guantánamo in 1837. In succeeding years a fairly ample system was built up between the cities of Pinar del Río and Santa Clara, with a number of short spurs farther eastward into the interior. After the first American occupation a private company built a line from Santa Clara to Santiago, more than half the length of the island, finally connecting its two ends (1902). The policy of the railways was always one rather of extortion than of fairness or of any interest in the development of the country, but better conditions have begun. There was ostensible government regulation of rates after 1877, but the roads were guaranteed outright against any loss of revenue, and in fact practically nothing was ever done in the way of development in them. The total revenue from roadways was 1907 m., of which 12,26 were of 17 public roads and 871 m. of 107 private roads. In August 1908 the mileage of all railways (including electric) in Cuba was 2,320-8 m. The telegraph and telephone systems are owned by the government. Cables connect the island with Florida, Jamaica, Haiti and San Domingo, Porto Rico, the lesser Antilles, Panama, Venezuela and Brazil. Havana, Santiago and Cienfuegos are cable ports. Wagon roads are still of small extent and primitive character save in a very few localities. The peculiar two-wheeled carts of the country, carrying enormous loads of 4 to 6 tons, destroy even the finest road. Similar carts, slightly lighter, used in the cities, quickly destroy any paving but stone block. The only good highways of any considerable length in 1908 were in the two western provinces and in the vicinity of Santiago. During the second American occupation work was begun on a network of good rural highways.

Population.—Various censuses were taken in Cuba beginning in 1774; but the results of those preceding the abolition of slavery, at least, are probably without exception extremely underestimates. The population in 1837 is estimated at 1,631,687, that of 1890 a population of 1,572,792 (the decrease of 3-6% is explained by the intervening war); and by the census of 1907 there were 2,094,980 inhabitants, 30-3% more than in 1890. The average settlement per square mile varied from 1,669 in Havana province to 11-8 in Camagüey, and was 46-4 for all of Cuba; the percentage of urban population (in cities, that is, with more than 1,000 inhabitants) in the different provinces varied from 18-2 in Pinar del Río to 74-7 in Havana, and was 43-9 for the entire island. There were five cities having populations above 25,000—Havana, 207,159; Santiago, 45,470; Matanzas, 36,009; Cienfuegos, 30,100; Puerto Príncipe (or Camagüey), 29,616; and fourteen more above 8,000—Cardenas, Manzanillo, Guanabacoa, Santa Clara, Sagua la Grande, Sancti Spiritus, Guantánamo, Trinidad, Pinar del Río, San Antonio de los Baños, Jovelanas, Marianao, Caibarién and Guantánamo. The proportion of the total population which in 1907 was in cities of 8,000 or more was only 30-3%; and the proportion in cities of 25,000 or more was 21-4%. Mainly owing to the large element of transient foreign whites without families (long charismatics), the city population of 1907 at 91-2 was very small in comparison. The Republic strongly encourages
immigration. In 1900–1906 there were 143,122 immigrants, of whom 124,865 were Spaniards, 45,574 were from the United States, 2,961 were Spanish Americans, and a few were Italian, Syrian, Chinese, French, English, &c. The Chinese element is a remnant of a former coolie population; their numbers in 1907 (11,217) were less than a fourth the number in 1887. Their introduction began in 1847 and ended in 1871. Conjugal conditions in Cuba are peculiar. In 1907 only 20.7% of the total population were legally married; an additional 8.6% were living in more or less permanent consensual unions, these being particularly common among the negroes. Including all unions the total is below the European proportion, but above that of Porto Rico or Jamaica in 1899.

The negro element is strongest in the province of Oriente and weakest in Camagüey; in the former it constituted 43.1% of the population, in the latter 18.3% and in Havana City 25.5%. In Guantánamo, in Santiago de Cuba, and in seven other towns they exceeded the whites in number. Calabrián and San Antonio de los Baños had the largest proportion of white population. The position of the negroes in Cuba is exceptional. Despite the long period of slavery they are decidedly below the whites in number. The Spanish slave laws (although in practice often frightfully abused) were always comparatively generous to the slave, making relatively easy, among other things, the purchase of his freedom, the number of free blacks being always great. Since the abolition of slavery the status of the black has been made more definite, and his rights naturally much greater. The wars of 1868–1878 and 1895–1898 and the threatened war of 1906 all helped to give to the negro element its high position. There is no antagonism between the divisions of the coloured race. All hold their own with the white in industrial usefulness to the community, and though the blacks are more backward in education and various other tests of social advancement, still their outlook is full of promise. There is practically no colour caste in Cuba; politically the negro is the white man's equal; socially there is very little ostensible inequality and almost perfect toleration. The negro in Cuba shows promising though undeveloped traits of landlord- ship. Women labour habitually in the fields. Segregation of blacks and whites was extremely common before emancipation. It is sometimes said that since then there has been a counter- tendency, but it is impossible to prove such a statement conclusively except with the aid of future censuses. Few of the negroes are black; some of the blackest have the regular features of the Caucasian; and racial mixtures are everywhere evidenced by colour of skin and by physiognomy. It seems certain that the African element has been holding its own in the population totals since emancipation.

Cuba is overwhelmingly Roman Catholic in religion, but under the new Republic there is a complete separation of church and state, and liberalism and indifference are increasing. Illiteracy is extremely widespread. In 1907 the census showed 56.0% (43,3 in 1899) of persons above ten years who could read. Of the voting population 53.2% of native white, and 37.3% of coloured Cuban citizens, and 71.6% of Spanish citizens could read. A reformation in education was begun the first year of the United States military occupation and continued under the Republic.

Constitution.—The constitution upon which the government of Cuba rests was framed during the period of the United States military government; it was adopted the 21st of February 1901, and certain amendments or conditions required by the United States were accepted on the 12th of June 1901. The constitution is republican and modelled on the Constitution of the United States, with some marked differences of greater centralization, due to colonial experience under the rule of Spain, notably as regards federalism; the provinces of the island being less important than the states of the American Union. The president of the Republic, who is elected for four years by an electoral college, and cannot hold office for more than two successive terms, has a cabinet whose members he may appoint and remove freely, their number being determined by law. He sanctions, promulgates and executes the laws, and supplements them (partly co-ordinately with congress) by administrative regulations in harmony with their ends; he holds a veto power and pardoning power; controls with the senate political appointments and removals; and conducts foreign relations, submitting treaties to the senate for ratification. Congress consists of two houses. The senate contains four members from each province, chosen for eight years; by a provincial electoral board, which consists of the provincial counsellors plus a double number of electors (half of them paying high taxes) who are selected at a special election by their fellow citizens. Half of the senators retire every four years. The senate is the court of trial for the president, officers of the cabinet, and provincial governors when accused of political offences. It also acts jointly with the president in political appointments and treaty making. The house of representatives, whose members are chosen directly by the citizens for four years, one-half retiring every two years, has the special power of impeaching the president and cabinet officers. Congress meets twice annually, in April and November. Its powers are extensive, including, in addition to ordinary legislative powers, control of financial affairs, foreign affairs, the army and navy and approve treaties of peace, amendments, and electoral legislation for the provinces and municipalities, control of the electoral vote for president and vice-president, and designation of an acting president in case of the death or incapacity of these officers. The subjects of legislative power are very similar to those of the United States congress; but control of railroads, canals and public roads is explicitly given to the federal government. Justice is administered by courts of various grades, with a supreme court at Havana as the head; the members of this being appointed by the president and senate. This court passes on the constitutionality of all laws, decrees and regulations.

There are six provinces—Pinar del Río, Havana, Matanzas, Santa Clara, Camagüey or Puerto Príncipe, and Oriente. Each has a provincial governor and assembly chosen directly by the people, generally charged with independent control of matters affecting the province; but the president may interfere against an abuse of power by either the governor or the assembly. Municipalities are also established by the president and are administered by mayors (alcaldes) and assemblies elected by the people, and control strictly municipal affairs. The “termo municipal” is the chief political and administrative civil division. It is an urban district together with contiguous rural territory. Its divisions are “barrios.” The president may interfere if necessary in the municipality as in the province; and so may the governor of the province. But all interference is subject to review of claims by the courts. Both provinces and municipalities are forbidden by the constitution to contract debts without a coincident provision of permanent revenue for their settlement.

The franchise is granted to every male Cuban twenty-one years of age, not mentally incapacitated, nor previously a convict of crime, nor serving in the army or navy of the state. Foreigners may become citizens in five years by naturalization. Church and state are completely separated, toleration being guaranteed for the profession and practice of all religious beliefs, and the government may not subsidize any religion.

Primary education is declared by the constitution to be free and compulsory; and its expenses are paid by the central government so far as it may be beyond the power of the province or municipality to bear them. Secondary and advanced education is controlled by the state. In the last days of Spanish rule (1894), there were 904 public and 704 private schools, and not more than 60,000 pupils enrolled; in 1900 there were 3550 public schools with an enrolment of 172,273 and an average attendance of 123,162. In the four school years from 1903–1904 to 1906–1907 the figures of enrolment and average attendance were 201,824 and 110,531; 194,957 and 105,706; 186,571 and 98,329; and 189,839 and 93,865. In 1906–1907 the percentage (31.6) of attendants to children of school age was twice as large as in 1898–1899. Private schools, some of very high grade, draw many pupils. Almost all schools are primary. The university of Havana (founded
CUBA

1768) was given greatly improved facilities, especially of material equipment, by the American military government, and seems to have begun an ambitious progress. In 1907 the number of students was 554. Below the university there are six provincial institutes, one in each province, in each of which there is a preparatory department, a department of secondary education, and (this due to peculiar local conditions) a school of surveying; and in that of Havana commercial departments in addition. In Havana, also, there is a school of painting and sculpture, a school of arts and trades, and a national library, all of which are supported or subventioned by the national government, as are also a public library in Matanzas, and the Agricultural Experiment Station at Santiago de las Vegas. In connexion with the university is a botanical garden; with the national sanitary service, a biological laboratory, and special services for small-pox, glanders and yellow fever. Independent of the government are various schools and learned societies in Havana (q.v.). A school was established by the government in Key West, Florida (U.S.A.), in 1905, for the benefit of the Cuban colony there. Finally, the government sustains about two score of penal establishments, reform schools, hospitals, dispensaries and asylums, which are scattered all over the island,—every town or any considerable size having one or more of these charities.

Under the colonial rule of Spain the head of government was a supreme civil-military officer, the governor and captain-general. His control of the entire administrative life of the island was practically absolute. Originally residents at Santiago de Cuba, the captains-general resided after 1850 at Havana. Because of the isolation of the eastern part of the island, the dangers from pirates, and the important considerations which had caused Santiago de Cuba (q.v.) to be the first capital of the island, Cuba was divided in 1697 into two departments, and a governor, subordinate in military matters to the captain-general at Havana, was appointed to rule the territory east of Puerto Príncipe. In 1801, when the audiencia—of which the captain-general was ex officio president—began its functions at that point, the governor of Santiago became subordinated in political matters as much as in military. Two chief courts of justice (audiencias) sat at Havana (after 1832) and Puerto Príncipe (1802–1853); appeals could go to Spain, who appointed presidents and vice-presidents—district judges and ordinary alcaldes or local judges. The audiencias also held important political powers under the Laws of the Indies. The captain-general of Cuba was not originally, however, by any means so broad in powers as the viceregalities of Mexico and Peru; and by the creation in 1765 of the office of intendant—the delegate of the national treasury—his faculties were very greatly curtailed. The great powers of the intendant were, however, merged in those of the governor-general in 1853; and the captain-general having been given by royal order in 1825 (several times later explicitly confirmed, and not revoked until 1870) the absolute powers (to be assumed at his initiative and discretion) of the governor of a besieged city, and by a royal order of 1834 the power to banish at will persons supposed to be inimical to the public peace; and by virtue of his office the president and dominator of all the important administrative boards of the government, held the government of the island, and in any emergency the liberty and property of its inhabitants, in his hand. The royal orders following 1825 developed a system of extraordinary and extreme repression. In 1828, as the result of the Ten Years' War, various administrative reforms, of a decentralizing tendency, were introduced. The six provinces were created, and had governors and assemblies ("diputaciones"); and a municipal law was provided that in many ways was a sound basis for local government. But centralization remained very great. In the municipality the alcalde (mayor) was appointed by the governor-general, and the ayuntamiento (council) was controlled by the veto of the provincial governor and by the assembly of the province. The deputation was subject in turn to the same veto of the provincial governor, and he controlled by the governor-general. There was besides a provincial commission of five lawyers named by the governor-general from the members of the delegation, who settled election questions, and questions of eligibility in this body, gave advice as to laws, acted for the deputation when it was not sitting, and in general facilitated centralised control of the administrative system. The character of this body was altered in 1860, and in 1868, in which latter year its functions were reduced to the essentially judicial. Despite superficial decentralization after 1875 any real growth of local self-government was rendered impossible. Moreover, no great reforms were made in the abuses naturally incident to the old personal system. Exile and imprisonment at the will of the government and without trial were common. Personal liberty, liberty of conscience, speech, assembly, petition, association, press, liberty of movement and security of home, were without real guarantee even within the extremely small limits in which they nominally existed. Under the constitution of the Republic the sphere of individual liberty is large and constitutionally protected against the government.

Finance.—There has been a great change in the budget of Cuba since the advent of the Republic. In 1891–1896 the average annual income was $20,798,930, the average annual expenditure $22,057,150. More than two-thirds of the revenue was derived from customs duties (two-thirds of the total duties). Of the expenditure more than ten million dollars annually went for the public debt, $5 to 6 millions for the army and navy, as much more for civil administration (including more than two millions for purely Peninsular services with which the colony was burdened); and on an average probably one million more went for sinecures. Every Cuban paid about twice as heavy taxes as a Spaniard of the Peninsula. Very little was spent on sanitation, roads, other public works and education. The revenue receipts under the Republic have increased especially over those of the old régime in the item of customs duties; and the expenditure is very differently distributed. Lotteries which were an important source of revenue under Spain were abolished under the Republic. The debt resting on the colony in 1895 (a large part of it as a result of the war of 1868–1878, the entire cost of which was laid upon the island, but a part as the result of Spain's war adventures in Mexico and San Domingo, home loans, &c.) was officially stated at $168,500,000. The attainment of independence freed the island from this debt, and from commercial restrictions in which it was placed, and duties imposed, especially the limitations of 1875, under which the island was burdened by Spain during the last insurrection. The debt of the Republic in April 1908 was $48,146,585, including twenty-seven millions which were assumed in 1902 for the payment of the army of independence, four for agriculture, and four for the payment of revolutionary debts, and $2,065,858, representing obligations assumed by the revolution's representative in the United States during the War of Independence. United States and British investments, always important in the agriculture and manufactures of the island, greatly increased following 1898, and by 1908 those of each nation were supposed to exceed considerably $100,000,000.

Archaeology.—Archaeological study in Cuba has been limited, and has not produced results of great importance. Almost nothing is actually known of prehistoric Cuba; and a few skulls and implements are the only basis existing for conjecture. Very little also is known as to the natives who inhabited the island at the time of the discovery. They were a tall race of copper hue; fairly intelligent, mild in temperament, who lived in poor huts and practised a fixed and primitive agriculture. How numerous they were when the Spaniards first came among them cannot be said; undoubtedly tradition has greatly exaggerated their number. They are supposed to have been practically extinct by 1550. Even in the 19th century reports were spread of communities in which Indian blood was supposedly still plainly dominant; but the conclusion of the competent scientists who have investigated such rumours has been that at least absolutely nothing of the language and traditions of the aborigines has survived.

History.—Cuba was discovered by Columbus in the course of his first voyage, on the 27th of October 1492. He died believing
Cuba was part of a continent. In 1508 Sebastian de Ocampo circumnavigated it. In 1511 Diego Velazquez began the conquest of the island. Baracoa (the landing point), Bayamo, Santiago de Cuba, Puerto Principe, Sancti Spiritus, Trinidad and the original Havana were all founded by 1515. Velazquez's reputation and legends of wealth drew many immigrants to the island. From Cuba went the expeditions that discovered Yucatan (1517), and explored the shores of Mexico, Hernando Cortés's expedition for the invasion of Mexico, and de Soto's for the exploration of Florida. The last two had a pernicious effect on Cuba, draining it of horses, money and of men. At least as early as 1523 the African slave trade was begun. In 1544 the Indians, so far as they had not succumbed to the labours of the mines and fields to which they were put by the Spaniards, were proclaimed emancipated. The administration in the 16th century was loose and violent. The local authorities were divided among themselves by bitter feud, the ecclesiastical against the civil, the ayuntamientos against the governors, and the admiralty officers among themselves; brigandage, mutinies and intestinal struggles disturbed the peace. As a result of the transfer of Jamaica to England, the population of Cuba was greatly augmented by Jamaican immigrants to about 30,000 in the middle of the 17th century.

The activity of English and French pirates began in the 16th century, and reached its climax in the middle of the 17th century. So early also began dissatisfaction with the economic regulations of the colonial system, even grave resistance to their enforcement; and illicit trade with privateers and foreign colonies had begun long before, and in the 17th and 18th centuries was the basis of the island's wealth. In 1762 Havana was captured after a long resistance by a British force under Admiral Sir George Pocock and the earl of Albemarle, with heavy loss to the besiegers. It was returned to Spain the next year in exchange for the Floridas. From this date begins the modern history of the island. The British opened the port to commerce and the slave trade, and revealed its possibilities. The government of Spain, beginning in 1764, made notable breaches in the old monoplastic system of colonial trade throughout America; and Cuba received special privileges, also, that were a basis for real prosperity. Spain paid increasing attention to the island, and in harmony with the policy of the Laws of the Indies many decrees intended to stimulate agriculture and commerce were issued by the crown, first in the form of monopolies, then with increased freedom and with bounties. Various colonial products and the slave trade were favoured in this way. After the cession of the Spanish portion of San Domingo to France hundreds of Spanish families emigrated to Cuba, and many thousand more immigrants, mainly French, followed them from the entire island during the revolution of the blacks. Most of them settled in Oriente province, where their names and blood are still apparent, and with their cafetales and tobacco monopolies, they continued to receive the rewards of their blood and to prosper.

Under a succession of liberal governors (especially Luis de las Casas, 1790–1796, and the marqués de Someruelos, 1799–1813), at the end of the 18th century and the first part of the 19th, the wars in Europe cut off Spain almost entirely from the colony, Cuba was practically independent. Trade was comparatively free, and worked a revolution in culture and material conditions. General Las Casas, in particular, left behind him in Cuba an undying memory of good efforts. Free commerce with foreigners—a fact after 1809—was definitely legalized in 1813 (confirmed in 1824). The state tobacco monopoly was abolished in 1817. The reported populations by the (untrustworthy) censuses of 1774, 1792 and 1817 were 161,670, 273,301 and 555,033. Something of political freedom was enjoyed during the two terms of Spanish constitutional government under the constitution of 1812. The sharp division between creoles and peninsulars (i.e. between those born in Cuba and those born in Spain), the question of annexation to the United States or possibly to some other power, the plotting for independence, all go back to the early years of the century.

Partly because of political and social divisions thus revealed, conspiracies being rife in the decade 1820–1830, and partly as preparation for the defence against Mexico and Colombia, who throughout these same years were threatening the island with invasion, the captains-general, in 1825, received the powers above referred to; which became, as time passed, monstrously in accord with the general tendencies of colonial government and with increasing liberties in Spain, but continued to be the spiritual basis of Spanish rule in the island. Among the governors of the 19th century Miguel Tacon, governor in 1834–1839, a forceful and high-handed soldier, deserves mention, especially in the annals of Havana; he ruled as a tyrant, made many reforms as regards law and order, and left Havana, in particular, full of municipal improvements. The good he did was limited to the spheres of public works and police; in other respects his rule was a pernicious influence for Cuba. Politically his rule was marked by the proclamation at Santiago in 1836, without his consent, of the Spanish constitution of 1834; he repressed the movement, and in 1837 the deputies of Cuba to the Cortes of Spain (to which they were admitted in the two earlier constitutional periods) were excluded from that body, and it was declared in the national constitution that Cuba (and Porto Rico) should be governed by "special laws." The inapplicability of many laws passed for the Peninsula—all of which under a constitutional system would apply to Cuba as to any other province, unless that system was modified—was indeed notorious; and Cuban opinion had repeatedly, through official bodies, protested against laws thus imposed that worked injustice, and had pleaded for special consideration of colonial conditions. The promise of "special laws" based upon such consideration was therefore not, in itself, unjust, nor unwellcome. But as the colony had no voice in the Cortes, while the "special laws" were never passed (Cuba expected special fundamental laws, reforming her government, and the government regarded the old Laws of the Indies as satisfying the obligation of the consulship); the captains-general remained quite supreme, under the will of the crown, and colonial discontent became stronger and stronger. The rule of Leopold O'Donnell was marked in 1844 by a cruel and bloody persecution of negroes for a supposed plot of servile war; O'Donnell's actions being partly due to the iniquity that had prevailed for some years over the supposed machinations of English abolitionists and even of English official residents in the island, and also over the mutual jealousies and supposed annexation ambitions of Great Britain and the United States.

A Cuban international question had arisen before 1820. Spain, the United States, England, France, Colombia and Mexico were all involved in it, the first four continually. In the eighteen-fifties a strong pro-slavery interest in the United States advocated the acquisition of the island. One feature of this was the "Ostend Manifesto" (see Buchanan, James), in which the ministers of the United States at London, Paris and Madrid declared that if Spain refused a money offer for the colony the United States should seize it. Their government gave this document publicity. The Cuban policy of Presidents Pierce and Buchanan (during 1853–1861) was mainly directed to acquiring the island. From 1849 to 1851 there were three abortive filibustering expeditions from the United States, two being under a Spanish general, Narcisco Lopez (1798–1851). The domestic problem, the problem of discontent in the island, had become acute by 1850, and from this time on to 1868 the years were full of conflict between liberal and reactionary sentiment in the colony, centring about the asserted connivance of the captains-general in the illegal slave trade (declared illegal after 1850 by the treaty of 1817 and 1835 between Great Britain and Spain), the notorious immorality and prodigal wastefulness of the government, and the selfish exploitation of the colony by Spaniards and the Spanish government. From early in the 19th century there had always been separatists, reformists and repressionists in the island, but they were individuals rather than groups. The last were peninsulars, the others mainly creoles, and among the wealthy classes of the latter the separatists gradually gained increasing support.
An ineffective and extremely corrupt administration, a grave economic condition, new and heavy taxes, military repression, recurring heavy deficits in the budget, adding to a debt (about $130,000,000 in 1868) already very large and burdensome, and the complete fiasco of the junta of inquiry of Cuban and Porto Rican representatives which met in Madrid in 1866-1867—all were important influences favouring the outbreak of the Ten Years’ War. Among those who waged the war were men who fought to compel reforms, others who fought for annexation to the United States, others who fought for independence. The reformists demanded, besides the correction of the above evils, action against slavery, assimilation of rights between peninsulars and creoles and the practical recognition of equality, e.g., in the matter of office-holding, a grievance centuries old in Cuba as in other Spanish colonies, and guarantees of personal liberties. The separatists, headed by Carlos Manuel de Céspedes (1819-1874), a wealthy planter who proclaimed the revolution at Yara on the 10th of October, demanded the same reforms, including gradual emancipation of the slaves with indemnity to owners, and the grant of free and universal suffrage. War was defined through the year 1868 as almost wholly to the E. provinces. The policy of successive captains-general was alternately uncompromisingly repressive and conciliatory. The Spanish volunteers committed horrible excesses in Havana and other places; the rebels also burned and killed indiscriminately, and the war became increasingly cruel and sanguinary. Intervention by the United States seemed probable, but did not come, and after alternations in the fortunes of war, Martinez Campos in January 1878 secured the acceptance by the rebels of the convention (pacto) of Zanjón, which promised amnesty for the war, liberty to slaves in the rebel ranks, the abolition of slavery, reforms in government, and colonial autonomy. A small rising after peace (the “Little War” of 1879-1880) was easily repressed. Gradual abolition of slavery was declared by a law of the 13th of February 1880; definitive abolition in 1886; and in 1893 the equal civil status of blacks and whites in all respects was proclaimed by General Calleja. There is no more evidence to warrant the wholly erroneous statement sometimes made that emancipation was an economic set-back to Cuba than could be gathered to support a judgment regarding the United States. Coolie importation from China had been stopped in 1871.

As for autonomy and political reforms it has already been remarked that the change from the old régime was only superficial. The Spanish constitution of 1876 was proclaimed in Cuba in 1881. In 1878-1895 political parties had a complex development. The Liberal party was of growing radicalism, the Union Constitutional party of growing conservatism; and after 1893 a Reformist party was launched that drew the compromisers and the waverers. The demands of the Liberals were as in 1868; those for personal and property rights were much more definitely stated, and among explicit reforms demanded were the separation of civil and military power, general recognition of administrative responsibility under a colonial autonomous constitutional régime; also among economic matters, customs reforms and reciprocity with the United States were demanded. As for the representation accorded Cuba in the Spanish Cortes, as a rule a quarter of her deputies were Cuban-born, and the claim of only a few autonomists to control the elections. Reciprocity with the United States was in force from 1891 to 1894 and was extremely beneficial to Cuba. Its cessation greatly increased dissatisfaction.

Discontent grew, and another war was prepared for. On the 23rd of February 1895 General Calleja suspended the constitutional guarantees. The leading chiefs of the Ten Years’ War took the field again—Maximó Gómez, Antonio Maco, Jose Marti, Calixto García and others. Unlike that war, this was carried to the western provinces, and indeed was fiercest there. Among the military means adopted by the Spaniards to isolate their foe were “trocchas” (i.e., entrenchments, barbwire fences, and lines of block-houses) across the narrow parts of the island, and “reconcentration” of non-combatants in camps guarded by the Spanish forces. The latter measure produced extreme suffering and much starvation (as the reconcentrados were largely thrown upon the charity of the beggarly communities in which they were huddled). In October 1897 the Spanish premier, P. M. Sagasta, announced the policy of autonomy, and the new dispensation was proclaimed in Cuba in December. But again all final authority was reserved to the captain-general. The system was never to have a practical trial, although a full government was quickly organized under it. The American people had sent food to the reconcentrados; President McKinley, while opposing recognition of the rebels, affirmed the possibility of intervention; Spain resented this attitude; and finally, in February 1898, the United States battleship “Maine” was blown up—by whom will probably never be known—in the harbour of Havana.

On the 20th of April the United States demanded the withdrawal of Spanish troops from the island. War followed immediately. A fine Spanish squadron seeking to escape from Santiago harbour was utterly destroyed by the American blockading force, on the 3rd of July; Santiago was invested by land forces, and on the 20th of July the city surrendered. Other operations in Cuba were slight. By the treaty of Paris, signed on the 10th of December, Spain “relinquished” the island to the United States in trust for its inhabitants; the temporary character of American occupation being recognized throughout the treaty, in accord with the terms of the American declaration of war, in which the United States disclaimed any intention to control the island except for its pacification, and expressed the determination to leave the island thereupon to the control of its people. Spanish authority ceased on the 1st of January 1899, and was followed by American “military” rule (January 1, 1899—May 20, 1902). During these three years the great majority of offices were filled by Cubans, and the government was made as different as possible from the military control to which the colony had been accustomed. Very much was done for public works, sanitation, the reform of administration, civil service and education. Most notable of all, yellow fever was eradicated where it had been endemic for centuries. A constitutional convention sat at Havana from the 5th of November 1900 to the 21st of February 1901. The provisions of the document that emerged had already been referred to. In the determination of the terms that should subsist between the new republic and the United States there were constant and prolonged discussions. The Platt Amendment was formally adopted by the United States in 1899, and accepted by Cuba (12th of June 1901) as a part of her constitution. By these Cuba was bound not to incur debts her current revenues will not bear; to continue the sanitary administration undertaken by the military government of intervention; to lease naval stations (since located at Bahia Honda and Guantánamo) to the United States; and finally, the right of the United States to intervene, if necessary, in the affairs of the island was explicitly affirmed in the provision, “That the government of Cuba consents that the United States may exercise the right to intervene for the protection of Cuban independence, the maintenance of a government adequate for the protection of life, property and individual liberty, and for discharging the obligations with respect to Cuba imposed by the treaty of Paris on the United States, now to be assumed and undertaken by the government of Cuba.” This status thus created is very exceptional in the history of international relations. The status of the Isle of Pines was left an open question by the treaty of Paris, but a decision of the Supreme Court of the United States has declared it (in a question of customs duties) to be a part of Cuba, and though a treaty to the same end did not secure ratification (1908) by the United States Senate, repeated efforts by American residents thereon to secure annexation to the United States were ignored by the United States government.

The first Cuban congress met on the 5th of May 1902, prepared to take over the government from the American military authorities, which it did on the 20th of May. Tomas Estrada Palma (1835-1908) became the first president of the Republic.
In material prosperity the progress of the island from 1902 to 1906 was very great; but in its politics, various social and economic elements, and political habits and social conditions of Cubans, which for convenience if ill befitted a democracy, led once more to revolution. Congress neglected to pass certain laws which were required by the constitution, and which, as regards municipal autonomy, independence of the judiciary, and congressional representation of minority parties, were intended to make impossible the abuses of centralized government that had characterized Spanish administration. Political parties were forming without very evident basis for differences outside questions of political patronage and the good or ill use of power; and, in the absence of the laws just mentioned, the Moderates, being in power, used every instrument of government to strengthen their hold on office. The preliminaries of the elections of December 1905 and March 1906 being marked by frauds and injustice, the Liberals deserted the polls at those elections, and instead of appealing to judicial tribunals controlled by the Moderates, issued a manifesto of revolt on the 28th of July 1906. This insurrection rapidly assumed large proportions. The government was weak and lacked moral support in the whole island. After repeated petitions from President Palma to intervene by the United States, commissioners (E. H. Taft, Secretary of War, and R. M. W. von Ahlen, Acting Secretary of State) were sent from Washington to act as peace mediators.

All possible efforts to secure a compromise that would preserve the Republic failed. The president resigned (on the 28th of September), Congress dispersed without choosing a successor, and as an alternative to anarchy the United States was compelled to proclaim on the 29th of September 1906 a provisional government,—to last "long enough to restore order and public confidence," and hold new elections. The insurrectionists promptly disbanded. Government was maintained under the Cuban flag,—the diplomatic and consular relations with even the united States remaining in outward forms unchanged; and the regular forms of the constitution were scrupulously maintained so far as possible. No use was made of American military force save as a passive background to the government. The government of intervention at first directed its main effort simply to holding the country together, without undertaking much that could divide public opinion or seem of unpalatable foreign impulse; and later to the establishment of a few fundamental laws which, with a few exceptions, were uniformly simple and liberal, and stability to a new native government. These laws strictly defined the powers of the president; more clearly separated the executive departments, so as to lessen friction and jealousies; reformed the courts; reformed administrative routine; and increased the strength of the provinces at the expense of the municipalities. On the 28th of January 1909 the American administration ceased, and the Republic was a second time inaugurated, with General José Miguel Gomez (b. 1856), the leader of the Miguelista faction of the Liberal party, as president, and Alfredo Zayas, the leader of the Zavista faction of the same party, as vice-president. The last American troops were withdrawn from the island on the 1st of May 1909.

Authorities.—General Description.—There is no trustworthy recent work on Cuba. A Gazetteer of Cuba (14 vols., Havana, 1854); M. Rodriguez-Ferrer, Naturalia y civilizacion de ... Cuba, vol. i. (Madrid, 1876). See also United States Geological Survey, Bulletin 102 (1902), H. Gannett, "A Gazetteer of Cuba," Ol general descriptions in English, in addition to travels cited below, may be cited R. T. Hill, Cuba and Porto Rico with the other West Indies (New York, 1868).

Fauna and Flora.—A. H. R. Grisebach, Catalogus plantarum Cubensium (Leipzig, 1866), and A. H. R. Grisebach, Flora Cubana: enumeratio plantarum novarum in insula Cuba (Leipzig, 1868); and Flora Cubana: enumeratio nova plantarum Cubensium (Havana, 1873); F. Poey et al., Repertorium florae-vegetabilis of the island of Cuba (2 vols., Havana, 1865-1868); and F. Poey, Memorias sobre la historia natural de ... Cuba (3 vols., Havana, 1842-1851, 12 vols.; issued also in French; vols. 3-12 being the 4th edition).
CUBE (Gr. κύβος, a cube), in geometry, a solid bounded by six equal squares, so placed that the angle between any pair of adjacent faces is a right angle. This solid is of particular importance in the geography and cosmology of the Greeks Plato (Timaeus) described the figure in the following terms: "The isosceles triangle which has its vertical angle a right angle . . . combined in sets of four, with the right angles meeting at the centre, form a single square. Six of these squares joined together formed eight solid angles, each produced by three plane right angles: and the shape of the body thus formed was cubical, having six square planes for its surfaces." In his cosmology Plato assigned this solid to "earth," for "earth" is the least mobile of the four (elements of fire, water, air and earth) and most plastic of bodies: and that substance must possess this nature in this highest degree which has its bases most stable.

The mensuration of the cube, and its relations to other geometrical solids are treated in the article POLYHEDRON; in the same article are treated the Archimedean solids, the truncated and snub-cube; reference should be made to the article CRYSTALLOGRAPHY for its significance as a crystal form.

A famous problem concerning the cube, namely, to construct a cube of twice the volume of a given cube, was attacked with great vigour by the Pythagoreans, Sophists and Platonists. It became known as the "Delian problem" or the "problem of the duplication of the cube," and ranks in historical importance with the problems of "trisecting an angle" and "squaring the circle." The origin of the problem is open to conjecture. The Pythagorean discovery of "squaring a square," i.e., constructing a square of twice the area of a given square (which follows as a corollary to the Pythagorean property of a right-angled triangle, viz. the square of the hypotenuse equals the sum of the squares on the sides), may have suggested the strictly analogous problem of doubling a cube. Eratosthenes (c. 200 B.C.), however, gives a picturesque origin to the problem. In a letter to Ptolemy Euergetes he narrates the history of the problem. The Delians, suffering a dire pestilence, consulted their oracles, and were ordered to double the volume of the altar to their tutelary god.

An attempt was made to solve the problem by means of the original; but the plague was unabated, the oracles not having been obeyed. The error was discovered, and the Delians applied to Plato for his advice, and Plato referred them to Eudoxus. This story is mere fable, for the problem is far older than Plato.

Hippocrates of Chios (c. 430 B.C.), the discoverer of the square of a lune, showed that the problem reduced to the determination of two mean proportions between two given lines, one of them being twice the length of the other. Algebraically expressed, if \( x \) and \( y \) be the required mean proportional and \( a, 2a \), the lines, we have \( a : x = x : y = 2a \), from which it follows that \( x^2 = 2a^2 \).

Although Hippocrates could not determine the proportions, his statement of the problem in this form was a great advance, for it was perceived that the problem of trisecting an angle was reducible to a similar form which, in the language of algebraic geometry, is to solve geometrically a cubic equation. According to Proclus, a man named Hippias, probably Hippias of Elis (c. 460 B.C.), trisected an angle with a mechanical curve, named the quadratrix (q.v.). Archytas of Tarentum (c. 450 B.C.) solved the problem by means of a spiral of a helix-cylinder; according to Eutocius, Menachmus solved them by means of the intersections of conic sections; and Eudoxus also gave a solution.

All these solutions were condemned by Plato on the ground that they were mechanical and not geometrical, i.e., they were not effected by means of circles and lines. However, no proper geometrical solution, in Plato's sense, was obtained; in fact it is now generally agreed that, with such a restriction, the problem is insoluble. The pursuit of mechanical methods furnished a stimulus to the study of mechanical loci, for example, the locus of a point carried on a rod which is caused to move according to a definite rule. Thus Nicomedes invented the conchoid (q.v.); Diocles the cissoid (q.v.); Diocles and Menelaus solved the quadratrix invented by Hippias; all these curves furnished solutions, as is also the case with the trisectrix, a special form of Pascal's limaçon (q.v.). These problems were also attacked by the Arabian mathematicians; Tobi ben Korra (836-901) is credited with a solution, while Abul Gud solved it by means of a parabola and an equilateral hyperbola.

In algebra, the "cube" of a quantity is the quantity multiplied by itself twice, i.e., if \( a \) be the quantity \( a \times a \times a = a^3 \) is its cube. Similarly the "cube root" of a quantity is another quantity which when multiplied by itself twice gives the original quantity; thus \( a^3 \) is the cube root of \( a \) (see ARITHMETIC and ALGEBRA).

A "cubic equation" is one in which the highest power of the unknown is the cube (see EQUATION); similarly, a "cubic curve" has an equation containing no term of a power higher than the third, the powers of a compound term being added together.

In mensuration, "cubature" is sometimes used to denote the volume of a solid; the word is parallel with "quadrature," to determine the area of a surface (see MENSURATION; INFINITESIMAL CALCULUS).
CUBEBS—CUBITT, SIR WILLIAM

CUBEBS (Arab. kabūbāḥ), the fruit of several species of pepper (Piper), belonging to the natural order Piperaceae. The cubebes of pharmacy are produced by Piper Cubeba, a climbing shrub indigenous to south Borneo, Sumatra, Prince of Wales Island and Java. It has round, ash-coloured, smooth branches; lanceolate, or ovate-oblong, somewhat leathery, shining leaves, 4 to 6½ in. long and 1½ to 2 in. broad. Male and female flowers are borne on different plants. The fruits are small, globose, about ½ in. in diameter, and not so large as white pepper; their contracted stalk-like bases are between ½ and ¾ in. in length; and from forty to fifty of them are borne upon a common stem. The cubeb is cultivated in Java and Sumatra, the fruits are gathered before they are ripe, and carefully dried. Commercial cubebes consist of the dried berries, usually with their stalks attached; the pericarp is greyish-brown, or blackish and wrinkled; and the seed, when present, is hard, white and oily. The odour of cubebes is agreeable and aromatic; the taste, pungent, acrid, slightly bitter and persistent. About 15% of a volatile oil is obtained by distilling cubebes with water; after rectification with water, or on keeping, this deposits rhombic crystals of camphor of cubebes, C_{16}H_{26}O, the liquid portion, has the formula C_6H_4. Cubebine, CH_2(O)C_6H_4.CH.CH.CH.OH, is a crystalline substance existing in cubebes, discovered by Eugène Soubeiran and Capitaine in 1839; it may be prepared from cubebine, or from the pulp left after the distillation of the oil. The drug, along with gum, fatty oils, and malates of magnesia and calcium, contains also about 1% of cubebic acid, and about 6% of a resin.

The dose of the fruit is 30 to 60 grains, and the British Pharmacopoeia contains a tincture with a dose of ½ to 1 drachm. The volatile oil—oleum cubebae—is also official, and is the form in which this drug is most commonly used; the dose being 5 to 20 minims, which may be suspended in mucilage or given after meals in a cachet. The drug has the typical actions of a volatile oil, but exerts some of them in an exceptional degree. Thus it is liable to cause a cutaneous erythema in the course of its excretion by the skin; it has a marked diuretic action; and it is a fairly efficient disinfectant of the urinary passages. Its administration causes the appearance in the urine of a salt of cubebic acid which is precipitated by heat or nitric acid, and is therefore liable to be mistaken for albumin, when these two most common tests for the occurrence of albuminuria are applied. Cubebes is frequently used in the form of cigarettes for asthma, chronic pneumonia and hay-fever. A small percentage of cubebes is also commonly included in lozenges designed for use in bronchitis, in which the antiseptic and expectorant properties of the drug are useful. But the most important therapeutic application of this drug is in gonorrhoea, where its antiseptic action is of much value. As compared with copiaba in this connexion cubebes has the advantages of being less disagreeable to take and somewhat less likely to disturb the digestive apparatus in prolonged administration. The introduction of the drug into medicine is supposed to have been due to the Arabian physicians in the middle ages. Cubebes were formerly candied and eaten whole, or used ground as a seasoning for meat. Their modern employment is for maintaining the internal action of a drug; and they were purchased in 1284 and 1285 by Lord Clare at 2s. 3d. and 2s. 9d. per lb respectively; and in 1307 1 lb for the king's wardrobe cost 9s., a sum representing about £3, 12s. in present value (Rogers, *Hist. of Agriculture and Prices*, i. 627-628, ii. 344).

A closely allied species, *Piper Chaul*, produces the African cubebes or West African black-pepper, the berry of which is smoother than that of common cubebes and usually has a curved pedicle. In the 14th century it was imported into Europe from the Grain Coast, under the name of pepper, by merchants of Rouen and Lippe.

CUBICLE (Lat. cubiculum), a small chamber containing a couch or a bed. The small rooms opening into the atrium of a Pompeian house are known as cubicula. In modern English schools "cubicle" is the term given to the separate small bedrooms into which the dormitories are divided, as opposed to the system of large open dormitories.

CUBITT, THOMAS (1788-1855). English builder, was born at Buxton, near Norwich, on the 25th of February 1788. Few men have exhibited greater self-reliance as early life in the pursuit of a successful career. In his nineteenth year, when he was working as a journeyman carpenter, his father died, and he tried to better his position by going on a voyage to India, as captain's joiner. He returned to London, two years after, in the possession of a small capital, and began business as a carpenter. The growth of his establishment was steady and rapid. He was one of the first to combine several trades in a "builder's" business; and this very much increased his success. One of the earlier works which gave him reputation was the London Institution in Finsbury Circus; but it is from 1834 that the vast building operations date which identify his name with many splendid ranges of London houses, such as Tavistock, Gordon, Belgrave and Lowndes Squares, and the district of South Belgravia. While these and similar extensive operations were in progress, a financial panic, which proved ruinous to many, was surmounted in his case by a determined spirit and his integrity of character. He took great interest in sanitary measures, and published, for private circulation, a pamphlet on the general drainage of London, the substance of which was afterwards embodied in a letter to *The Times*; the plan he advocated was subsequently adopted by the conveyance of the sewage matter some distance below London. He advocated the provision of open spaces in the environs of London as places of public recreation, and was one of the originators of Battersea Park, the first of the people's parks. At a late period he received professionally the recognition of royalty, the palace at Osborne being erected after his designs, and under his superintendence; and in the *Life of the Prince Consort* he is described by Queen Victoria as one "than whom a better and kinder man did not exist." In 1851, although he was not identified with the management of the Great Exhibition, he showed the warmest sympathy with its objects, and aided its projector in many ways, especially in the profitable investment of its surplus funds. Cubitt, when he rose to be a capitalist, never forgot the interests and well-being of his workpeople. He was elected president of the Builders' Society some time before his death, which took place at his seat Denbies, near Dorking, on the 20th of December 1855.

His son, George Cubitt (1828-...), who had a long and useful parliamentary career, as Conservative member for West Surrey (1860-1865) and Mid-Surrey (1883-1892), was in 1892 raised to the peerage as Baron Ashcombe.

CUBITT, SIR WILLIAM (1785-1861). English engineer, was born in 1785 at Dilham in Norfolk, where his father was a miller. After serving an apprenticeship of four years (1800-1804) as a joiner and cabinetmaker at Stalham, he became associated with an agricultural-machine maker, named Cook, who resided at Swanton. In 1807 he patented self-regulating sails for windmills, and in 1812 he entered the works of Messrs Ransome of Ipswich, where he soon became chief engineer, and ultimately a partner. Meanwhile, the subject of the employment of criminals had been much in his thoughts; and the result was his introduction of the treadmill about 1818. In 1826 he removed to London, and in 1831 he was appointed to the office of civil engineer. Among his works were the Oxford canal, the Birmingham & Liverpool Junction Canal, the improvement of the river Severn, the Bute docks at Cardiff, the Black Sluice drainage and its outfall sluice at Boston harbour, the Middlesborough docks and coal drops in the Tees, and the South-Eastern railway, of which he was chief engineer. The Hanoverian government consulted him about the harbour and docks at Harburg; the water-works of the city of Berlin were constructed under his immediate superintendence; he was asked to report on the construction of the Paris & Lyons railway; and he was consulting engineer for the line from Boulogne to Amiens. Among his later works were two floating landing stages at Liverpool, and the bridge for carrying the London turnpike across the Medway at Rochester. In 1853, when he was president of the Institution of Civil Engineers, he was knighted for his services in connexion with the buildings erected in Hyde Park for the exhibition of that year.
CUCHULINN — CUCKOO

He retired from active work in 1838, and died on the 13th of October 1866, at his house on Clapham Common, London. He was born to Joseph Cubitt (1817–1872), was trained under him, and was engineer of various railways, including the Great Northern, London, Chatham & Dover, and part of the London & South-Western.

CUCHULINN (Cuchulinn; pronounced “Coooolinn”), the chief warrior in the Conchobar-Cuchulinn or older heroic (Ulster) cycle of Ireland. The story of his origin is very obscure. The god Lug is represented as having been swallowed in a draught of wine by his mother Dechtire, sister of Conchobar, who was king of Ulster. But it is not unlikely that this story was invented to supersede the account of the incestuous union of Conchobar with his sister, which seems to be hinted at on various occasions. Usually, however, he is styled son of Sualdam, an Ulster warrior who plays a very inferior part in the cycle. His earliest name was Setanta, and he was brought up at Dun Imhrith (Louth). When he was six years of age he announced his intention of going to Conchobar’s court at Emain Macha (Navan Rath near Armagh) to play with the boys there. He defeats all the boys in moveable fashion and is received as one of their number. Shortly after he kills Culann, the smith’s hound, a huge watch-dog. The smith laments that all his property is of no value now that his watchman is slain, whereupon the young hero offers to guard his domains until awhelp of the hound’s has grown. From this the boy received the name of Cú Chulinn or Culann’s Hound.

The next year Cuchulinn receives arms, makes his first foray, and slays the three sons of Necht, redoubtable hereditary foes of the Ulstermen, in the plain of Meath. The men of Ulster decide that Cuchulinn must marry, as all the women of Ireland are in love with him. Chosen envoys fail to find a bride worthy of him after a year’s search, but the hero goes straight to Emer, the daughter of Forgall the Wily, at Lusk (county Dublin). The lady is promised to him if he will go to learn chivalry of Domnall the Soldierly and the amazon Scathach in Alba. After enduring great hardships he goes through the course and leaves a son Conlaech behind in Scotland by another amazon, Aife. On his return he carries off and weds Emer. He is represented as living at Dun Delgan (Dundalk). The greatest of all the hero’s achievements was the defence of the frontier of Ulster against the forces of Medb, queen of Connaught, who had come to carry off the famous Brown Bull of Cualinga (Cooley). The men of Ulster were all suffering from a strange debility, and Cuchulinn had to undertake the defence single-handed from November to February. This was when he was seventeen years of age. The cycle contains a large number of episodes, such as the gaining of the champion’s portion and the tragic death by the warrior’s hand of his own son Conlaech. When he was twenty-seven he met with his end at the hands of Lugaid, son of Caróí MacDaire, the famous Munster warrior, and the children of Calatin Dána, in revenge for their father’s death (see CERR: Irish Literature).

Medieval Christian syncretists make Cuchulinn’s death take place about the beginning of the Christian era. It is not necessary to regard Cuchulinn as a form of the solar hero, as some writers have done. Most, if not all, of his wonderful attributes may be ascribed to the Irish prehistoric period, and it is true that Cuchulinn seems to stand in a special relation to the Tuatha De Danann leader, the god Lug, but in primitive societies there is always a tendency to ascribe a divine parentage to men who stand out pre-eminently in prowess beyond their fellows.

See A. Nutt, Cuchulainn, the Irish Achilles (London, 1900); E. Hull, The Cuchulinn Saga (London, 1898). (E. C. Q.)

CUCKOO, or Cuckoo, as the word was formerly spelt, the common name of a well-known and often-heard bird, the Cuculus canorus of Linnaeus. In some parts of the United Kingdom it is more frequently called gowk, and it is the Gr. κουκου, the Ital. cuccuò or cucco, the Fr. coucou, the Ger. Kuckuck, the Dutch kookhoek, the Dan. kubber or gjob, and the Swed. gök. The oldest English spelling of the name seems to have been cucco.

No single bird has perhaps so much occupied the attention of both naturalists and of those who are not naturalists, or has had so much written about it, as the common cuckoo, and of no bird perhaps have more idle tales been told. Its strong and, according to the experience of most people, its singular habit of entrusting its offspring to foster-parents is enough to account for much of the interest which has been so long felt in its history; but this habit is shared probably by many of its Old World relatives, as well as in the New World by birds which are not in any degree related to it. The cuckoo is a summer visitor to the whole of Europe, reaching even far within the Arctic circle, and crossing the Mediterranean from its winter quarters in Africa at the end of March or beginning of April. Its arrival is at once proclaimed by the peculiar and in nearly all languages onomatopoeic cry of the cock—a true song in the technical sense of the word, since it is confined to the male sex and to the season of love. In a few days the cock is followed by the hen, and amorous contests between keen and loud-voiced suitors are to be commonly noticed, until the respective pretensions of the rivals are decided. Even by night they are not silent; but as the season advances the song is less frequently heard, and the cuckoo seems rather to avoid observation as much as possible, the more so since whenever it shows itself it is a signal for all the small birds of the neighbourhood to be up in its pursuit, just as though it were a hawk, to which indeed its mode of flight and general appearance give it an undoubted resemblance—a resemblance that misleads some into confounding it with the birds of prey, instead of recognizing it as a harmless if not a beneficial destroyer of hairy caterpillars. Thus pass away some weeks. Towards the middle or end of June its “plain-song” cry alters; it becomes rather hoarser in tone, and its first syllable or note is doubled. Soon after it is no longer heard at all, and by the middle of July an old cuckoo is seldom to be found in the British Islands, though a stray example, or even, but very rarely, two or three in company, may occasionally be seen for a month longer. Of its breeding comparatively few have any personal experience. Yet a diligent search for and peering into the nests of several of the commonest little birds—more especially the pied wagtail (Motacilla lugubris, the titlark (Anthus pratensis), the reed-bunting (Emberiza schoeniclus), and the hedge-sparrow (Accenter modularis)—will be rewarded by the discovery of the egg of the mysterious stranger which has been surreptitiously introduced, and those who wait till this egg is hatched may be witnesses (as was Edward Jenner in the 18th century) of the murderous eviction of the rightful tenants of the nest by the intruder, who, hoisting them one after another on his broad back, heaves them over to die neglected by their own parents, of whose solicitous care he thus becomes the only object. In this manner he thrives, and, so long as he remains in the country of his birth his wants are anxiously supplied by the victims of his mother’s dupery. The actions of his foster-parents become, when he is full grown, almost ludicrous, for they often have to perch between his shoulders to place in his gaping mouth the delicate morsels he is too indolent or too stupid to take from their bills. Early in September he begins to shift for himself, and then follows the seniors of his kin to more southern climes. So much caution is used by the hen cuckoo in choosing a nest in which to deposit her egg that the act of insertion has been but seldom witnessed. The nest selected is moreover often so situated, or so built, that it would be an absolute impossibility for a bird of her size to lay her egg therein by sitting upon the fabric as birds commonly do; and there have been a few fortunate observers who have actually seen the deposition of the egg upon the ground by the cuckoo, who, then taking it in her bill, introduces it into the nest. Of these, the earliest in Great Britain seem to have been two Scottish lads, sons of Mr Trimen, a farmer in Coxmore, who, as recorded by Macgillivray (Brit. Birds, iii. 130, 131) from information communicated to him by Mr Durham Weir, saw most part of the operation performed, June 24, 1838. But perhaps the most satisfactory evidence on the point is that of Adolf Müller, a forester at Gladenbach in Darmstadt, who says (Zool. Garten, 1866, pp. 374, 375) that through a telescope he watched a cuckoo as she laid her egg on a
bank, and then conveyed the egg in her bill to a wagtail's nest. Cuckoos, too, have been not unfrequently shot by they were carrying a cuckoo's egg, presumably their own, in their bill, and this has probably given rise to the vulgar, but seemingly groundless, belief that they suck the eggs of other kinds of birds. More than this, Mr. G. D. Rowley, who had much experience of cuckoos, declares (Ibis, 1865, p. 185) his opinion to be that traces of violence and of a struggle between the intruder and the owners of the nest at the time of introducing the egg often appear, whence we are led to suppose that the cuckoo ordinarily, when inserting her egg, excites the fury (already stimulated by her hawk-like appearance) of the owners of the nest by turning out one or more of the eggs that may be already laid therein, and thus induces the dupe to brood all the more readily and more strongly what is left to her. Of the assertion that the cuckoo herself takes any interest in the future welfare of the egg she has foisted on her victim, or of its product, there is no good evidence.

But a much more curious assertion has also been made, and one that at first sight appears so incomprehensible as to cause little surprise at the neglect it long encountered. To this currency is first given by Salerne (L'Hist. nat. &c., Paris, 1751, p. 42), who was, however, hardly a believer in it, and it is to this effect, as he was told by an inhabitant of Sologne, that the egg of a cuckoo resembles in colour that of the eggs normally laid by the kind of bird in whose nest it is placed. In 1853 the same notion was prominently and independently brought forward by Dr A. C. E. Baldamus (Naumannia, 1853, pp. 307-325), and in time became known to English ornithologists, most of whom were naturally sceptical as to its truth, since no likeness whatever is ordinarily apparent in the very familiar case of the blue-green egg of the hedge-sparrow and that of the cuckoo, which is so often found beside it. Dr Baldamus based his notion on a series of eggs in his cabinet,1 a selection from which he figured in illustration of his paper, and, however the thing may be accounted for, it seems impossible to resist, save on one supposition, the force of the testimony these specimens afford. This one supposition is that the eggs have been wrongly ascribed to the cuckoo, and that they are only exceptionally large examples of the eggs of the birds in the nests of which they were found, for it cannot be gainsaid that some such abnormal examples are occasionally to be met with. But it is well known that abnormally large eggs are not only often deficient in depth of colour, but still more often in stoutness of shell. Applying these rough criteria to Dr Baldamus's series, most of the specimens stood the test very well.

There are some other considerations to be urged. For instance, Herr Braune, a forester at Greiz in the principality of Reuss (Naumannia, tom. cit. pp. 307, 313), shot a hen cuckoo as she was leaving the nest of an icterine warbler (Hypolais icterina). In the oviduct of this cuckoo he found an egg coloured very like that of the warbler, and on looking into the nest he found there an exactly similar egg, which there can be no reasonable doubt had just been laid by that very cuckoo. Moreover, Herr Gronau (Journ. far Orn., 1873, p. 434) afterwards found one of these most abnormally coloured specimens, quite unlike the ordinary egg of the cuckoo, to contain an embryo so fully formed as to show the characteristic cygodactyl feet of the bird, thus proving unquestionably its parentage.

On the other hand, we must bear in mind the numerous instances in which not the least similarity can be traced—as in the not uncommon case of the hedge-sparrow already mentioned, and if we attempt any explanatory hypothesis it must be one that will fit all round. Such an explanation seems to be this. We know that certain kinds of birds resent interference with their nests much less than others, and among them it may be asserted that the hedge-sparrow will patiently submit to various experiments. She will brood with complacency the egg of a redbreast (Erithacus rubecula), so unlike her own, and for aught we know to the contrary may even be colour-blind. In the case of such a species there would be no need of anything further to ensure success—the terror of the nest-owner a. seeing her home invaded by a hawk-like giant, and some of her treasures tossed out, would be enough to stir her motherly feelings so deeply that she would without misgiving, if not with joy that something had been spared to her, resume the duty of incubation so soon as the danger was past. But with other species it may be, and doubtless is, different. Here assimilation of the introduced egg to those of the rightful owner may be necessary, for there can hardly be a doubt as to the truth of Dr Baldamus's theory as to the object of the assimilation being to render the cuckoo's egg "less easily recognized by the foster-parents as a substituted one." It is especially desirable to point out that there is not the slightest ground for imagining that the cuckoo, or any other bird, can voluntarily influence the colour of the egg she is about to lay. Over that she can have no control, but its destination she can determine. It would seem also impossible that a cuckoo, having laid an egg, should look at it, and then decide for its appearance in the nest of the same nest she should put it. That the colour of an egg-shell can be in some mysterious way affected by the action of external objects on the perceptive faculties of the mother is a notion too wild to be seriously entertained. Consequently, only one explanation of the facts can here be suggested. Every one who has sufficiently studied the habits of animals will admit the influence of heredity. That there is a reasonable probability of each cuckoo most commonly putting her eggs in the nest of the same species of bird, and of this habit being transmitted to her posterity, does not seem to be a very violent supposition. Without attributing any wonderful sagacity to her, it does not seem unlikely that the cuckoo which had once successfully foisted her egg on a reed-wren or a titlark should again seek for another reed-wren's or another titlark's nest (as the case may be), when she had another egg to dispose of, and that she should continue her practice from one season to another. It stands on record (Zoologist, 1865, p. 307) that magpies placed their nest for eight or ten years running in almost exactly the same spot, and that in each of those years they fostered a young cuckoo, while many other cases of like kind, though not perhaps established on so good authority, are believed to have happened. Such a habit could hardly fail to become hereditary, so that the daughter of a cuckoo which always put her egg into a reed-wren's, titlark's or wagtail's nest would do as her mother. Furthermore it is unquestionable that whatever variation there may be among the eggs laid by different individuals of the same species, there is a strong family likeness between the eggs laid by the same individual, even at the interval of many years, and it can hardly be questioned that the eggs of the daughter would more or less resemble those of her mother. Hence the supposition may be fairly credited that the habit of laying a particular style of egg is also likely to become hereditary. Combining this supposition with that as to the distinct habit of laying the nest of the same species becoming hereditary, it will be seen that it requires only an application of the principle of natural selection to show the probability of this principle operating in the course of time to produce the facts asserted by the anonymous Solognot of the 18th century, and by Dr Baldamus and others since. The particular genus of cuckoo which inherited and transmitted the habit of depositing in the nest of any particular species of bird eggs having more or less resemblance to the eggs of that species would prosper most in those members of the genus where the likeness was strongest, and the other members would (ceteris paribus) in time be eliminated. As already shown, it is not to be supposed that all species, or even all individuals of a species, are duped with equal ease. The operation of this kind of natural selection would be most needed in those cases where the species are not easily duped—that is, in those cases which occur the least frequently. Here it is we find it, for observation shows that eggs of the cuckoo incubated in nests of the red-backed shrike (Lanius collurio), of the hunting (Emberiza miliaria), and of the icterine warbler approximate in their colouring to eggs of those species—species in whose nests the cuckoo rarely (in comparison with others) deposits eggs.
Of species which are more easily duped, such as the hedge-sparrow, mention has already been made.

More nearly allied to the British cuckoo are many other forms of the genus from various parts of Africa, Asia and their islands, while one even reaches Australia. In some cases the chief difference is said to lie in the diversity of voice—a character only to be appreciated by those acquainted with the living birds, and though of course some regard should be paid to this distinction, the possibility of birds using different “dialects” according to the locality they inhabit may make it a slender specific diagnostic. All these forms are believed to have essentially the same habits as the British cuckoo, and, as regards parasitism, the same is to be said of the large cuckoo of southern Europe and North Africa (Coccyx glandarius), which victimizes pies (Pica maurusa) and Cyanopica cooks) and crows (Corus cornix).

True it is that an instance of this species, commonly known as the great spotted cuckoo, having built a nest and hatched its young, is on record, but the later observations of others tend to cast doubt on the credibility of the ancient report. It is worthy of remark that the eggs of this bird so closely resemble those of the closely related species in whose nest they have been found, that even expert zoologists have been deceived by them, only to discover the truth when the cuckoo’s embryo had been extracted from the supposed pie’s egg. This species of cuckoo, easily distinguishable by its large size and long crest, has more than once made its appearance as a stranger in the British Isles. Equally parasitic are many other cuckoos, belonging chiefly to genera which have been more or less clearly defined as Cacomantis, Chrysococcyx, Eudynamis, Oryxophas, Polyphumia and Surniculus, and inhabiting parts of the Ethiopian, Indian and Australian regions; but there are certain aberrant forms of Old World cuckoos which unquestionably do not shirk parental responsibilities. Among these especially are the birds placed in or allied to the genera Centropus and Cucu— the former having a wide distribution from Egypt to New South Wales, living much on the ground and commonly called lark-heeled cuckoos; the latter bearing no English name, and limited to the island of Madagascar. These build a nest, not perhaps in a highly finished style of architecture, but one that serves its end.

Respecting the cuckoos of America, the evidence, though it has been impugned, is certainly enough to clear them from the charge which attaches to so many of their brethren of the Old World. There are two species very well known in parts of the United States and some of the West Indian Islands (Coccyx americanus and C. erythropthalmus), and each of them has occasionally visited Europe. They both build nests remarkably small structures when compared with those of other birds of their size—and faithfully incubate their delicate sea-green eggs. In the south-western states of the Union and thence into Central America is found another curious form of cuckoo (Geococcyx)—the chaparral-cock of northern and paisano of southern settlers. The first of these names it takes from the low brushwood (chaparral) in which it chiefly dwells, and the second is said to be due to its pheasant-like (Jassian corrupt into paisano, properly a courser) cry. As is usual in such cases, one of the two species of the genus was formerly described as a Phasianus. They both have short wings, and seem never to fly, but run with great rapidity. Returning to arboresal forms, the genera Neomorphus, Diplopterus, Saurothero and Physa (the last two commonly called rain-birds, from the belief that their cry portends rain) may be noticed—all of them belonging to the Neotropical region; but perhaps the most curious form of American cuckoos is the ani (Crotophaga), of which three species inhabit the same region. The best-known species (C. ani) is found throughout the Antilles and on the opposite continent. In most of the British colonies it is known as the black witch, and is accused of various malpractices—it being, in truth, a perfectly harmless if not a beneficial bird. As regards its propagation this aberrant form of cuckoo departs in one direction from the normal habit of birds, for several females, unite to lay their eggs in one nest. It is evident that incubation is carried on socially, since an intruder on approaching the rule nest will disturb perhaps half a dozen of its sable proprietors, who, loudly complaining, seek safety either in the leafy branches of the tree that holds it, or in the nearest available covert, with all the speed that their feeble powers of flight permit. (A. N.)

**CUCUCKO-SPIT.** A frothy secretion found upon plants, and produced by the immature nymphal stage of various plant-lice of the familiar Cercopoidea and Jassidea, belonging to the homopterous division of the Hemiptera, which in the adult condition are sometimes called frog-hoppers.

**CUCUMBER** *(Cucumis sativus, Fr. concoumbr, O. Fr. concombre, whence the older English spelling and pronunciation "cowmber," the standard in England up to the beginning of the 18th century), a creeping plant of the natural order Cucurbitaceae. It is widely cultivated, and originated probably in northern India, where Alphonse de Candolle affirms (Origin of Cultivated Plants) that it has been cultivated for at least three thousand years. It spread westward to Europe and was cultivated by the ancient Greeks under the name of *Cucumis*, and it did not reach China until two hundred years before the Christian era. It is an annual with a rough succulent trailing stem and stalked hairy leaves with three to five pointed lobes; the stem bears branched tendrils by means of which the plant can be trained to supports. The short-stalked, bell-shaped flowers are unisexual, but staminate and pistillate are borne on the same plant; the latter are recognized by the swollen warty green ovary below the rest of the flower. The ovary develops into the “cucumber” without fertilization, and unless seeds are wanted, it is advisable to pinch off the male flowers.

There are a great many varieties of cucumber in cultivation, which may be grouped under the two headings (1) forcing, (2) field varieties.

1. The former are large-leaved strong-growing plants, not suited to outdoor culture, with long smooth-fruited fruit; there are many excellent varieties such as Telegraph, Son House, Duke of Edinburgh, &c. The plants are grown in a hot-bed which is prepared towards the end of February from rich stable manure, leaves, &c. A rich turfy loam with a little well-decomposed stable manure forms a good soil. The seeds are sown singly in rich, sandy soil in small pots early in February and plunged in a bottom heat. After they have made one or two foliage-leaves the seedlings are transferred to larger pots, and ultimately about the middle of March to the hot-bed. Each plant is placed in the centre of a mound of soil about a foot deep and well watered with tepid water. The plants should be well watered during their growing period, and the foliage sprinkled or syringed two or three times a day. In bright sunshine the plants are lightly shaded. When grown in frames the tops of the main stems are pinched off when the stems are about 2 ft. long; this causes the development of side shoots on which fruits are borne. When these have produced one or two fruits, they are also stopped at the joint beyond the fruit. When grown in greenhouses the vines may be allowed to reach the full length of the house before they are stopped. If the fruit is to be kept for long, they may be grown in cylindrical glass tubes, and supported by small wooden troughs. If seeds are required one or more female flowers should be selected and pollen from male flower placed on their stigmas.

2. The outdoor varieties are known as hill or ridge cucumbers. They may be grown in any good soil. A warm, sheltered spot with a south aspect and a mound of rich, sandy loam with a little leaf-mould placed over a hot-bed of dung and leaves is recommended. The mounds or ridges should be 4 to 5 ft. apart, and one plant is placed in the centre of each. The seeds are sown in March in light, rich soil in small pots with gentle heat. The seedlings are repotted and well hardened for planting out in June. The plants must be well watered in and, until established, shaded by a hand-light from bright sunshine. When the leading shoots are from 13 to 2 ft. long the tips are pinched off to induce the formation of fruit-bearing side-shoots. If seed is required a pistillate
flower is selected and pollinated. There are numerous varieties distinguished by size and the smooth or prickly rind. King of the Ridge has smooth fruits a foot or more long; gherkin, a short, prickly form, is much used for pickling.

Cucumber is subject to the attacks of green fly, red spider and thrips; for the two latter, infected leaves should be sponged with soapy water; for green fly careful fumigating is necessary.

The Sikkim cucumber, C. sativus var. sikkimensis, is a large fruited form, reaching 15 in. long by 6 in. thick, grown in the Himalayas of Sikkim and Nepal. It was discovered by Sir Joseph Hooker in the eastern Himalayas in 1848. He says "so abundant were the fruits, that for days together I saw gnawed fruits lying by the natives' paths by thousands, and every man, woman and child seemed engaged throughout the day in devouring them." The fruit is reddish-brown, marked with yellow, and is eaten both raw and cooked.

The West India gherkin is Cucumis Anguria, a plant with small, slender vines, and very abundant small ellipsoid green fruit covered with warts and spines. It is used for pickling.

Cucumbers were much esteemed by the ancients. According to Pliny, the emperor Tiberius was supplied with them daily, both in summer and winter. The kishuim or cucumbers of the scriptures (Num. xi. 5; Isa. i. 8) were probably a wild form of C. Medo, the melon, a plant common in Egypt, where a drink is prepared from the ripe fruit. Peter Forskal, one of the early botanical writers on the country, describes its preparation. The pulp is broken and stirred by means of a stick thrust through a hole cut at the umbilicus of the fruit; the hole is then closed with wax, and the fruit, without removing it from its stem, is buried in a little pit; after some days the pulp is found to be converted into an agreeable liquor (see Flora egyptiaca-arabica, p. 168, 1775). The squirting cucumber, Ecballium Elaterium, the Dioscurypos of Theophrastus, furnishes the drug elaterium (q.v.).

See Naudin in Annal. des sci. nat. ser. 4 (Botany), t. xi. (1859); G. Nicholson, Dictionary of Gardening (1885); L. H. Bailey, Cyclopedia of American Horticulture (1900).

CUCURBITACEAE, a botanical order of dicotyledons, containing 87 genera and about 600 species, found in the temperate and warmer parts of the earth but especially developed in the tropics. The plants are generally annual herbs, climbing by means of tendrils and having a rapid growth. The long-stalked leaves are arranged alternately, and are generally palmately lobed and veined. The flowers or inflorescences are borne in the leaf-axils, in which a vegetative bud is also found, and at the side of the leaf-stalk is a simple or branched tendril. There has been much difference of opinion as to whether members or members the tendril represents; the one which seems most in accordance with facts regards the tendril as a shoot, the lower portion representing the stem, the upper twining portion a leaf. The flowers are unisexual, and strikingly epigynous, the perianth and stamens being attached to a bell-shaped prolongation of the receptacle above the ovary. The five narrow pointed sepals are followed by five petals which are generally united to form a more or less bell-shaped corolla. There are five stamens in the male flowers; the anthers open towards the outside, are one-celled, with the pollen-sacs generally curved and variously united. The carpels, normally three in number, form an ovary with three thick, fleshy, bifid placentas bearing a large number of ovules on each side, and generally filling the interior of the ovary with a juicy mass. The short thick style has generally three branches, each bearing a fleshy, usually forked stigma. The fruit is a fleshy many-seeded berry with a tough rind (known as a pepo), and often attains considerable size. The embryo completely fills the seed.

The order is represented in Britain by Bryonia (Bryonia dioica), (fig. 1) a hedge-climber, perennial by means of large fleshy tubers which send up each year a number of slender angular stems. The leaves are heart-shaped with wavy marginated lobes. The flowers are greenish, ½ to ¾ in. in diameter; the fruit, a red several-seeded berry, is about ½ in. in diameter.

Many genera are of economic importance; Cucumis (fig. 2) affords cucumber (q.v.) and melon (q.v.); Cucurbita, pumpkin and marrow; Citrus vulgaris is water-melon, and C. Colocynthis, colocynth; Ecballium Elaterium (squirtling cucumber) is medicinal; Sechium edule (chocho), a tropical American species, is largely cultivated for its edible fruit; it contains one large seed which germinates in situ. Lageneria is the gourd (q.v.). The fruits of Luffa angulata have a number of closely netted vascular bundles in the pericarp, forming a kind of loose felt which supplies the well-known loofah or bath-sponge.

Cuddalore, a town of British India, in the South Arcot district of Madras, on the coast 125 m. S. of Madras by rail. Pop. (1901) 52,216, showing an increase of 10% in the decade. It lies low, but is regarded as exceptionally healthy, and serves as a kind of sanatorium for the surrounding district. The principal exports are sugar, oil-seeds and indigo. There are two colleges and two high schools. In the neighbourhood are the ruins of Fort St David situated on the river Gadilam, which has
CUDDAPAH—CUDWORTH

as stirring a history...any spot in the Presidency. As a small fort built by a Hindu merchant it fell into the hands of the Maharrats after the capture of Gingi by Sivaji in 1667. From them it was purchased by the English in 1690, the purchase including not only the fort but the adjacent towns and villages “within ye random shott of a piece of ordnance.” A great gun was fired to different points of the compass and all the country within its range, including the town of Cuddalore, passed into the possession of the English. The villages thus obtained are still spoken of as “cannon ball villages.” From 1725 onwards the fortifications were greatly strengthened. In 1746 Fort St. David became the British headquarters for the south of India, and Dupleix’ attack was successfully repulsed. Clive was appointed its governor in 1756; in 1758 the French captured it, but abandoned it two years later to Sir Eyre Coote. In 1782 they again took it and restored it sufficiently to withstand a British attack in 1783. In 1785 it finally passed into British possession.

CUDDAPAH, a town and district of British India, in the Madras Presidency. The town is 6 m. from the right bank of the river Pennar, and 161 m. by rail from Madras. Pop. (1901) 17,414. It is a market-place, but has some trade in cotton and indigo, and manufactures of cotton cloth. Hills surround it on three sides, and it has a bad reputation for unhealthiness.

The District of Cuddapah has an area of 8723 sq. m. It is in shape an irregular parallelogram, divided into two nearly equal parts by the range of the Eastern Ghats, which intersects it throughout its entire length. The two tracts thus formed possess totally different features. The first, which constitutes the north, east and south-east of the district, is a low-lying plain; while the other, which comprises the southern and south-western portion, forms a high table-land from 1500 to 2500 ft. above sea-level. The chief river is the Pennar, which enters the district from Bellary on the west, and flows eastwards into Nellore. Though a large and broad river, and in the rains containing a great volume of water, in the hot weather months it dwindles down to an incon siderable stream. Its principal tributaries are the Kundaur, Saglaier, Chennar, and Papagni rivers. One of the most interesting antiquities in the district is the ancient fort of Gurramkonda. The fort is supposed to have been built by the Golconda sultans; it stands on a hill 500 ft. high, three sides of which consist of almost perpendicular precipices. According to a local legend the name Gurramkonda, meaning “horse hill,” was derived from the fact that a horse was supposed to be guardian of the fort and that the place was impregnable so long as the horse remained there. The story goes that a Maharrat chief at length succeeded in scaling the precipice and in carrying off the horse, and although the thief was captured before reaching the base of the hill, the spell was broken and the fort, when next attacked, fell. The population of the district in 1901 was 1,291,267. The principal crops are millet, rice, other food grains, pulse, oil-seeds, cotton and indigo. The two last are largely exported. There are several steam factories for pressing cotton, and indigo vats. The district is served by lines of the Madras and the South Indian railways.

CUDWORTH, RALPH (1617-1688), English philosopher, was born at Aller, Somersetshire, the son of Dr. Ralph Cudworth (d. 1624), rector of Aller, formerly fellow of Emmanuel College, Cambridge. His father died in 1624, and his mother then married the Rev. Dr. Stoughton, who gave the boy a good home education. Cudworth was sent to his father’s college, was elected fellow in 1636, and became a successful tutor. In 1642 he published A Discourse concerning the true Notion of the Lord’s Supper, and a tract entitled The Union of Christ and the Church. In 1645 he was appointed master of Clare Hall and the same year was elected Regius professor of Hebrew. He was now recognized as a leader among the remarkable group known as the Cambridge Platonists (q.v.). The whole party were more or less in sympathy with the Commonwealth, and Cudworth was consulted by John Thurloe, Cromwell’s secretary of state, in regard to university and government appointments. His sermons, such as that preached before the House of Commons, on the 31st of March 1649, advocate principles of religious toleration and charity. In 1650 he was presented to the college living of North Cadbury, Somerset. From the diary of his friend John Worthington we learn that Cudworth was nearly compelled, through poverty, to leave the university, but in 1654 he was elected master of Christ’s College, whereupon he married. On the Restoration he contributed some Hebrew verses to the Academiae Cantabrigiensis Sororpa, a congratulatory volume addressed to the king. In 1662 he was presented to the rectory of Ashwell, Herts. In 1665 he almost quarrelled with his fellow-Platonist, Henry More, because the latter had written an ethical work which Cudworth feared would interfere with his own long-contemplated treatise on the same subject. To avoid clashing, More brought out his book, the Enchiridion ethicum, in Latin; Cudworth’s never appeared. In 1678 he published The True Intellectual System of the Universe: the first part, wherein all the reason and philosophy of atheism is confuted and its impossibility demonstrated (imprimatur dated 1671). No more was published, perhaps because of the theological clamour raised against this first part. Cudworth was installed prebendary of Gloucester in 1678. He died in the first week of June 1688, and was buried in the chapel of Christ’s. His only surviving child, Damaris, a devout and talented woman, became the second wife of Sir Francis Masham, and was distinguished as the friend of John Locke. Much of Cudworth’s work still remains in manuscript; A Treatise concerning eternal and immutable Morality was published in 1731; and A Treatise of Free-will, edited by John Allen, in 1838; both are connected with the design of his magnus opus, the Intellectual System.

The Intellectual System arose, so its author tells us, out of a discourse refuting “fatal necessity,” or determinism. Enlarging his plan, he proposed to prove three matters: (a) the existence of God; (b) the naturalness of moral distinctions; and (c) the reality of human freedom. These three together make up the intellectual (as opposed to the physical) system of the universe; and they are opposed respectively by three false principles, atheism, religious fatalism which refers all moral distinctions to the will of God, and thirdly the fatalism of the ancient Stoics, who recognized God and yet identified Him with nature. The intellectual system deals with the soul, and was published by its author. Cudworth criticizes two main forms of materialistic atheism, the atomic, adopted by Democritus, Epicurus and Hobbes; and the hylozoic, attributed to Strato, which explains everything by the supposition of an inward self-organizing life in matter. Atomic atheism is by far the more important, if only because Hobbes, the great antagonist whom Cudworth always has in view, is supposed to have held it. It arises out of the combination of two principles, neither of which is atheistic taken separately, i.e. atomism and corporeality, or the doctrine that nothing exists but body. The example of Stoicism, as Cudworth points out, shows that corporeality may be theistic. Into the history of atomism Cudworth plunges with vast erudition. It is, in its purely physical application, a theory that he fully accepts; he holds that it was taught by Pythagoras, Empedocles, and in fact, nearly all the ancient philosophers, and was only perverted to atheism by Democritus. It was then invented, he believes, before the Trojan war, by a Sidonian theologian named Mochus, who is identical with the Moses of the Old Testament. In dealing with atheism Cudworth’s method is to marshal the atheistic arguments elaborately, so elaborately that Dryden remarked “he has raised such objections against the being of a God and Providence that many think he has not answered them”; then in his last chapter, which by itself is as long as an ordinary treatise, he confines them with all the reasons that his reading could supply. A subordinate matter in the book that attracted much attention at the time is the conception of the “Plastic Medium,” which is a mere revival of Plato’s “World-Soul,” and is meant to explain the existence and laws of nature without referring all to the direct operation of God. It occasioned a long-drawn controversy between Pierre Bayle and Le Clerc, the former
CUEUC——CUIRASS
Real belong to the wide plain of La Mancha (q.v.). The rocky and bare highland of Cuenca on the north and east includes the upper valley of the Jucar and its tributary streams, but in the north-west the province is watered by tributaries of the Tagus. The forests are proverbial for their pine timber, and rival those of Soria; considerable quantities of timber are floated down the Tagus to Aranjuez and thence taken to Madrid for building purposes. Excessive droughts prevail; the climate of the hills and of the high plateaus is harsh and cold, but the valleys are excessively hot in summer. The soil, where well watered, is fertile, but little attention is paid to agriculture, and three-fourths of the area is left under pasture. The rearing of cattle, asses, mules and sheep is the principal employment of the people; olive oil, nuts, wine, wheat, silk, wax and honey are the chief products. Iron, copper, alum, salt-petre, jasper and agates are found, but in 1903 all the workings had been abandoned except three salt mines; and there are few manufactures except the weaving of coarse cloth. The roads are in such a backward condition that they cripple not only the mining interests but also the exports of timber, and at the beginning of the 20th century there was no railway except a branch line which passed westwards from Almansa through Tarancón to Cuenca, the capital (Pop. in 1900, 10,756). No other town has as many as 8,000 inhabitants, and no other Spanish province is so thinly populated as Cuenca. In 1900 there were only 37,6 inhabitants per sq. m. Education is backward, and extreme poverty almost universal among the peasantry. See also CASTILE.

CUEUC, the capital of the Spanish province of Cuenca; 123 m. by rail E. by S. of Madrid. Pop. (1900) 10,756. Cuenca occupies a height of the well-watered Serrania de Cuenca, at an elevation of 2060 ft., overlooking the confluence of the rivers Jucar and Huecar. A fine bridge, built in 1523, crosses the Jucar to the convent of San Pablo. Among several interesting churches in the city, the most noteworthy is the 13th-century Gothic cathedral, celebrated for the beautiful carved woodwork of its 16th-century doorway, and containing some admirable examples of Spanish sculpture. The city has a considerable trade in timber, and was long the headquarters of the provincial wool industry; the loss of which, in modern times, has partly been compensated by the development of soap, paper, chocolate, match, and leather. The Moors, who finally captured the city in 1097, were driven out by Alphonso VIII of Castile in 1177, and shortly afterwards became an episcopal see. In 1874 it offered a prolonged and gallant resistance to the Carlist rebels.

CUESTA, a name of Spanish origin used in New Mexico for low ridges of steep descent on one side and gentle slope on the other. It has been proposed as a term for the land form which consists of the two elements of a steep scarp or "strike" face, and an inclined plain or gentle "dip" slope.

CUEVAS DE VERA, a town of south-eastern Spain, in the province of Almeria; on the right bank of the river Almanzora, 8 m. W. of the Mediterranean Sea. Pop. (1900) 20,562. Cuevas de Vera is built at the eastern extremity of the Sierra de los Filabres (683 ft.), which isolate it from the railway system of Almeria. It is, however, the chief market for the rich agricultural districts towards the south and for the argentineferous and other mines among the mountains. In appearance it is modern, with wide streets, two fine squares, and a parish church in Doric style. From 1691 to 1758. But in reality the town is of considerable antiquity. One of the towers in the Moorish palace owned by the marquesses of Villafranca is probably of Roman origin.

CUFF. (1) (Of uncertain origin), the lower edge of a sleeve turned back to show an ornamental border, or with an addition of lace or trimming; now used chiefly of the stiff bands of linen worn under the coat-sleeve either loose or attached to the shirt. (2) Also uncertain in origin, but with no connexion, probably, with (1), a blow with the hand either open or closed, as opposed to the use of weapons.

CUIRASS (Fr. cuirasse, Lat. coriaceus, made of leather, from corium, the original breastplate being of leather), the plate armour, whether formed of a single piece of metal or other material or composed of two or more pieces, which covers the

maintaining, the latter denying, that the Plastic Medium is really favourable to atheism.

No modern reader can endure to toll through the Intellectual System; its only interest is the light it throws upon the state of religious thought after the Restoration, when, as Birch puts it, "irreligion began to lift up its head." It is immensely diffuse and pretentious, loaded with digressions, its argument buried under masses of fantastic, uncritical learning, the work of a vigorous but quite unoriginal mind. As Bolingbroke said, Cudworth "read too much to think enough, and admired too much to think freely." It is no canality that natural procrastination, or the clamour caused by his candid treatment of atheism and by certain heretical tendencies detected by orthodox criticism in his view of the Trinity, made Cudworth leave the work unfinished.

A much more favourable judgment must be given upon the short Treatise on eternal and immutable Morality, which deserves to be read by those who are interested in the historical development of British moral philosophy. It is an answer to Hobbes's famous doctrine that moral distinctions are created by the state, an answer from the standpoint of Platonism. Just as knowledge contains a permanent intelligible element over and above the flux of sense, so also the intellectual ideas of morality. Cudworth's ideas, like Plato's, have a constant and never-failing entity of their own," such as we see in geometrical figures; but, unlike Plato's, they exist in the mind of God, whence they are communicated to finite understandings. Hence "it is evident that wisdom, knowledge and understanding are eternal and self-subsistent things, superior to matter and all sensible beings, and independent upon them"; and so also are moral good and evil. At this point Cudworth stops; he does not attempt to give any list of Moral Ideas. It is, indeed, the cardinal weakness of this form of intuitionism that no satisfactory list can be given and that no moral principles have the "constant and never-failing entity," or the definiteness, of the concepts of geometry. Henry More, in his Enchiridion ethicum, attempts to enumerate the "nomens moralia"; but, so far from being self-evident, most of his moral axioms are open to serious controversy.

The Intellectual System was translated into Latin by J. L. Mosheim and furnished with notes and dissertations which were translated into English by H. Harrow's edition (1845). Our chief biographical authority is T. Birch's "Account," which appears in editions of the Works. There is a good chapter on Cudworth in J. Tulloch's Rational Theology, vol. ii. Consult also P. Janet's Essai sur le médiateur plastique (1866), W. R. Scott's Introduction to the "Treatise," and J. Martineau's Types of Ethical Theory, vol. ii. (H. St.)

CUEUC, a city and the capital of the province of Azuay, Ecuador, about 190 m. S. of Quito and 70 m. S.E. of Guayaquil. Pop. (1908 estimate) 30,000 (largely Indians), including the suburb of Ejido. Cuenca stands at the northern end of a broad valley, or basin, of the Andes, lying between the transverse ridges of Azuay and Loja, and is about 8640 ft. above sea-level. Near by is the hill of Tarqui which the French astronomers chose for their meridian in 1742. Communication with the coast is difficult. Cuenca is the third most important city of Ecuador, being the seat of a bishopric, and having a college, a university faculty, a cathedral, and several churches, and a considerable industrial and commercial development. It manufactures sugar, woolen goods and pottery, and exports Peruvian bark (cinchona), hats, cereals, cheese, hides, &c. It was founded in 1557 on the site of a native town called Tumibamba, and was made an episcopal see in 1786.

CUEUC, a province of central Spain bounded on the N. by Guadalajara, N.E. by Teruel, E. by Valencia, S. by Albacete, S.W. by Ciudad Real, W. by Toledo and N.W. by Madrid. Pop. (1900) 249,606; area, 6636 sq. m. Cuenca occupies the eastern part of the ancient kingdom of New Castile, and slopes from the Serrania de Cuenca (highest point the Cerro de San Felipe, on the north-eastern border of the province, 2905 ft.), down into the great southern Castilian plain watered by the upper streams of the Guadiana. The lowlands bordering on Ciudad
CUIRASSIERS—

front of the wearer's person. In a suit of armour, however, since this important piece was generally worn in connexion with a corresponding defence for the back, the term is understood to imply the complete body-armour, including the breast and the back plates. Thus this complete body-armour appears in the middle ages frequently to have been described as both a "pair of plates." The corselet (Fr. corselet, diminutive of the O. Fr. corse, body), a comparatively light cuirass, is more strictly a breast-plate only. As parts of the military equipment of classical antiquity, cuirasses and corselets of bronze, and at later periods also of iron or some other rigid substance, were habitually in use; but while some special kind of secondary protection for the breast had been worn in earlier times by the men-at-arms in addition to their mail hauberks and their "cotes" with splints and studs, it was not till the 14th century that a regular body-defence of plate can be said to have become an established component of medieval armour. As this century continued to advance, the cuirass is found gradually to have come into general use, in connexion with plate defences for the limbs, until, at the close of the century, the long familiar interlinked chain-mail is no longer visible in knighthly figures, except in the camaril of the bassinet and at the edge of the hauberk. The prevailing, and indeed almost the universal, usage throughout this century was that the cuirass was worn covered. Thus, the 14th century form of the breast-armour of the Black Prince, in his effigy in Canterbury cathedral, 1376, indicates that a breast-plate as well as a hauberk is to be considered to have been covered by the royalty-emblazoned jupon of the prince. The cuirass, thus worn in the 14th century, was always made of sufficient length to rest on the hips; otherwise, if not thus supported, it must have been suspended from the shoulders, in which case it would have effectively interfered with the free and vigorous action of the wearer. Early in the 15th century, the entire panoply of plate, including the cuirass, began to be worn without any surcoat; but in the concluding quarter of the century the short surcoat, with full short sleeves, known as the tabard, was in general use over the armour. At the same time that the disuse of the surcoat became general, small plates of various forms and sizes (and not always made in pairs, the plate for the right or sword-arm often being smaller and lighter than its companion), were attached to the armour in front of the shoulders, to defend the otherwise vulnerable points where the plate defences of the upper-arms and the cuirass left a gap on each side. About the middle of the century, instead of being formed of a single plate, the breast-plate of the cuirass was made in two parts, the lower adjoined to the upper, to overlap the upper, and contrived by means of a strap or sliding rivet. As the period of chivalry, during which the half of the 15th century the cuirass occasionally was superseded by the "brigantine jacket," a defence formed of some textile fabric, generally of rich material, lined throughout with overlapping scales (resembling the earlier "imbricated" form) of metal, which were attached to the jacket by rivets, having their heads, like studs, visible on the outside. In the 16th century, when occasionally, and by personages of exalted rank, splendid surcoats were worn over the armour, the cuirass—its breastplate during the first half of the century, globular in form—was constantly reinforced by strong additional plates attached to it by rivets or screws. About 1550 the breast-piece of the cuirass was characterized by a vertical central ridge, called the "tapul," having near its centre a projecting point; this projection, somewhat later, was brought lower down, and eventually the profile of the plate, the projection having been carried to its base, assumed the singular form which led to this fashion of the cuirass being distinguished as the "peascod cuirass."

Corselets provided with both breast and back pieces were worn by foot-soldiers in the 17th century, while their mounted companions wore half-cuirasses in heavier and stronger cuirasses; and these defences continued in use after the other pieces of armour, one by one, had gradually been laid aside. Their use, however, never altogether ceased, and in modern armies mounted cuirassiers, armed as in earlier days with breast and back plates, have in some degree emulated the martial splendour of the body-armour of the era of medieval chivalry. Some years after Waterloo certain historical cuirasses were taken from their regiment in the town of London, and adapted for service by the Life Guards and the Horse Guards. For parade purposes, the Prussian Gardes du Corps and other corps wear cuirasses of richly decorated leather.

CUIRASSIERS, a kind of heavy cavalry, originally developed out of the men-at-arms or gendarmes forming the heavy cavalry of feudal armies. Their special characteristic was the wearing of full armour, which they retained long after other troops had abandoned it. Hence they became distinguished as cuirassiers. The first Austrian corps of kyrissers was formed in 1484 by the emperor Maximilian and was 100 strong. In 1705 Austria possessed twenty regiments of cuirassiers. After the war of 1666, however, the existing regiments were converted into dragoons. Russia has likewise in modern times abolished all but a few guard regiments of cuirassiers. The Prussian cuirassiers were first so called under Frederick William I, and in the wars of his successor Frederick the Great they bore a conspicuous part. After the Seven Years' War they ceased to wear the cuirass on service, but after 1814 these were reintroduced, the spoils taken from the French cuirassiers being used to equip the troops. The cuirass is now worn only on ceremonial parades. In France the cuirassiers date from 1666, when a regiment, subsequently numbered 8th of the line, was formed. During the time that Emperor Charles V was created, until in 1812 there were fourteen. The number was reduced after the fall of Napoleon, but in modern times it has been again increased. The French regiments alone in Europe wear the cuirass on all parades and at manoeuvres.

CUJAS (or Cujactus), Jacques (or as he called himself, Jacques de Cujas) (1520-1560), French jurist, was born at Toulouse, where his father, whose name was Cujas, was a fuller. Having taught himself Latin and Greek, he studied law under Arnaud Ferrier, then professor at Toulouse, and rapidly gained a great reputation as a lecturer on Justinian. In 1554 he was appointed professor of law at Cahors, and about a year after L'Hôpital called him to Bourges. Duren, however, who also held a professorship at Bourges, stirred up the students against the new professor, and such was the disorder produced in consequence that Cujas was glad to yield to the storm, and accept an invitation he had received to the university of Valence. Recalled to Bourges at the death of Duren in 1559, he remained there till 1567, when he returned to Valence. There he gained a European reputation, and collected students from all parts of the continent, among whom were Joseph Scaliger and de Thou. In 1575 Charles IX appointed Cujas counsellor to the parlement of Grenoble, and in the following year a pension was bestowed on him by Henry III. Margaret of Savoy induced him to remove to Turin; but after a few months (1575) he once more took his old place at Bourges. But the religious wars drove him thence. He was called by the king to Paris, and permission was granted him by the parlement to lecture on civil law in the university of the capital. A year after, however, he finally took up his residence at Bourges, where he remained till his death in 1560, in spite of a handsome offer made him by Gregory XIII. In 1584 to attract him to Bologna.

The life of Cujas was altogether that of a scholar and teacher. In the religious wars which filled all the thoughts of his contemporaries he steadily refused to take any part. *Nihil hoc ad *edictum praetoris, "this has nothing to do with the edict of the praetor," was his usual answer to those who spoke to him on the subject. His surpassing merit as a jurisconsult consisted in the fact that he turned from the ignorant commentators on Roman law to the Roman law itself. He consulted a very large number of manuscripts, of which he had collected more than 500 in his own library; but, unfortunately, he left orders in his will that his library should be divided among a number of purchasers, and his collection was thus scattered, and in great part lost. His emendations, on which a large number were published under the title of *Animadversiones et observationes*, were not confined to law-books, but extended to many of the Latin and Greek classical
authors. In jurisprudence his study was far from being devoted solely to Justianin; he recovered and gave to the world a part of the Theodosian Code, with explanations; and he procured the manuscript of the Basilica, a Greek abridgment of Justianin, afterwards published by Fabrot (see BASILICA). He also composed a commentary on the Constituciones Feudorum, and on some books of the Decretals. In the Parotilia, or summaries which he made of the Digest, and particularly of the Code of Justinian, he condensed into short axioms the elementary principles of law, and gave definitions remarkable for their admirable clearness and precision. His lessons, which he never dictated, were continuous discourses, for which he made no other preparation than that of profound meditation on the subjects to be discussed. He was impatient of interruption, and upon the least noise he would instantly quit the chair and retire. He was strongly attached to his pupils, and Scaliger affirms that he lost more than 4000 livres by lending money to such of them as were in want.

In his lifetime Cujas published an edition of his works (Neville, 1577). It is beautiful and exact, but incomplete; it is now very scarce. The edition of Colombet (1604) is also incomplete. Fabrot, however, collected the whole in the edition which he published at Paris (1658), in 10 vols. 12mo, and which was reprinted at Naples (1722, 1727), in 11 vols. folio, and at Naples and Venice (1758), in 10 vols. folio, with an index forming an eleventh volume. In the editions of Napoleon and of the Continent 1 the gaps which were not to be found in that of Fabrot, particularly a general table, which will be found very useful, and interpretations of all the Greek words used by Cujas.

See Barrière-Masson, Vie de Cujas (Paris, 1590); Terrasson, Histoire de la jurisprudence romaine, et Maîtrises d'histoire, de littérature, et de jurisprudence; Bernardi, Eloge de Cujas (Lyons, 1775); Hugo, Civilistisches Magazin; Berriat Saint Prix, Mémoires de Cujas, appended to his Histoire du droit romain; Biographie universelle; Gravina, De ortu et progressu juris civilis; Spangenberg, Cujacius und seine Zeitgenossen (Leipzig, 1882).

CULDees, an ancient monastic order with settlements in Ireland and Scotland. It was long fondly imagined by Protestant and especially by Presbyterian writers that they had preserved primitive Christianity free from Roman corruptions in one remote corner of western Europe, a view enshrined in Thomas Campbell's Requulpta:

"Peace to their shades. The pure Culldees
Were Albyn's earliest priests of God,
Ere yet an island of her sea
By foot of Saxon monk was trod."

Another view, promulgated like the above by Hector Boece in his Latin history of Scotland (1516), makes them the direct successors in the 9th to the 12th century of the organized Irish and Culldean monasticism of the 6th to the 8th century. Both these views were disproved by William Reeves (1815-1892), bishop of Down, Connor and Dromore.

As found in the Irish MSS. the name is Céile Dé, i.e. God's orvade or sworn ally. It was latinated as Coli dei, whence Boece's culdei. The term seems, like the Latin vir dei, to have been applied generally to monks and hermits. There are very few trustworthy ancient sources of information, but it seems probable that the Rule of Chrodegang, 1 archbishop of Metz (d. 766), was brought by Irish monks to their native land from the monasteries of north-eastern Gaul, and that Irish anchorites originally unfettered by the rules of the cloister bound themselves by it. In the course of the 9th century we find mention of nine places in Ireland (including Armagh, Clonmacnoise, Clones, Devenish and Sligo) where communities of these Culdees were established as a kind of annex to the regular monastic institutions. They seem especially to have had the care of the poor and the sick, and were interested in the musical part of worship. Meanwhile in Scotland the Iona monks had been expelled by the Pictish king Nechtan in 717, and the vacancies thus caused were filled by the Roman monks who throned into the north from Northumbria. Into the gap, towards the end of the 8th century, came the Culdees from Ireland. The features of their life in Scotland, which is the most important epoch in the history of the order, resemble closely those of the secular canons of England and the continent. From the outset they were more or less isolated, and, having no fixed forms or common head, tended to decay. In the 12th century the Celtic Church was completely metamorphosed on the Roman pattern, and in the process the Culdees also lost any distinctiveness they may formerly have had, being brought, like the secular clergy, under canonical rule. The pictures that we have of Culdece life in the 12th century vary considerably. The chief houses in Scotland were at St Andrews, Dunkeld, Lochleven, Monymusk in Aberdeenshire, Abernethy and Brechin. Each was an independent establishment controlled entirely by its own abbot and apparently divided into two sections, one priestly and the other lay and even married. At St Andrews about the year 1100 there were thirteen Culdees holding office by hereditary tenure and paying more regard to their own prosperity and aggrandizement than to the services of the church or the needs of the populace. A much-needed measure of reform, inaugurated by Queen Margaret, was carried through by her sons Alexander I. and David I.; gradually the whole position passed into the hands of Turgot and his successors in the bispohip. Canons Regular were instituted and some of the Culdees joined the new order. Those who declined were allowed a liferent of their revenues and lingered on as separate bodies even dwindling both till the beginning of the 14th century, when, excluded from voting at the election of the bishop, they disappear from history. At Dunkeld, Crinan, the grandfather of Malcolm Canmore, was a lay abbot, and tradition says that even the clerical members were married, though like the priests of the Eastern Church, they lived apart from their wives during their term of sacerdotal service. The Culdees of Lochleven lived on St Sert's Inch, which had been given them by a Pictish prince, Brude, about 850. In 1093 they surrendered their island to the bishop of St Andrews in return for perpetual food and clothing, but Robert, who was bishop in 1144, handed over all their vestments, books, 2 and other property, with the island, to the newly founded Canons Regular, in which probably the Culdees were incorporated. There is no trace of such partial independence as was experienced at St Andrews itself, possibly because the bishop's grant was backed up by a royal charter. In the same fashion the Culdees of Monymusk, originally perhaps a colony from St Andrews, became Canons Regular of the Augustinian order early in the 13th century, and those of Abernethy in 1273. At Brechin, famous like Abernethy for its round tower, the Culdee prior and his monks helped to form the chapter of the diocese founded by David I. in 1145, though the name persisted for a generation or two. Similar absorptions account for the disappearance of the Culdees of York, a name borne by the canons of St Peter's about 925, and of Snowdon and Bardsey Island in north Wales mentioned by Gildas Cambrensis (c. 1100) in his Speculum Ecclesiae and Itinerarium respectively. The former community was, he says, sorely oppressed by the covetous Cistercians. These seem to be the only cases where the Culdees are found in England and Wales. In Ireland the Culdees of Armagh endured until the dissolution in 1541, and enjoyed a fleeting resurrection in 1627, soon after which their ancient property passed to the vicars choral of the cathedral.

See W. Reeves, The Culdees of the British Islands (Dublin, 1864); W. F. Skene, Celtic Scotland (1876-1880), especially vol. ii., W. Beveridge, Makers of the Scots Church (1908). The older view will be found in J. Jamieson's Historical Account of the Ancient Culdees (1811).

Culebra, the smaller of two islands lying in the Virgin Passage immediately E. of Porto Rico and known as the Islas de Passaje. It is about 18 m. distant from Cape San Juan and rises from the same submerged plateau with the larger islands of the Antilles. Its extreme dimensions are 3 by 6 m., and its surface is low and comparatively uniform, which gives the

1 Devised originally for the clergy of Chrodegang's cathedral, it was largely an adaptation of St Benedict's rule to secular clergy living in common. In 816 it was confirmed, with certain modifications, by the synod of Aix-la-Chapelle, and became the law for collegiate and cathedral churches in the Frankish empire. See CANON.
prevailing winds an unbroken sweep across it. For this reason the rainfall is limited to a short season, and the population is compelled to store rainwater in cisterns for drinking purposes. Its soil is fertile, and cattle, poultry, vegetables and small fruits are produced. The island has been a dependency of Porto Rico since 1879, when its colonization was formally undertaken, and it is now described as a ward of the Vieques district of the department of Humacao. In 1902 the American naval authorities selected the Playa Sardinas harbour on the S. side of Culebra as a rendezvous of the fleet and marine encampments were located on shore. The strategic position of the island, its healthiness and its continued use as a naval station have given it considerable importance. Its population was 704 in 1899, which had increased to nearly 1200 in 1903.

CULLEN, PAUL (1803-1878), cardinal and archbishop of Dublin, was born near Ballyitore, Co. Kildare, and educated first at the Quaker school at Carlow and afterwards at Rome, where he joined the Urban College of the Propaganda and, after passing a brilliant course, was ordained in 1830. He then became vice-rector, and afterwards rector, of the Irish National College during the Revolution of 1848; he was rector of the Urban College, saving the property under the protection of the American flag. In 1849, on the strong recommendation of Archbishop John MacHale of Tuam, Cullen was nominated as successor to the primatial see of Armagh; and, on his return to Ireland, presided as papal delegate at the national council of Thurlres in the August of 1850. Taking a strong line on the educational question which was then agitating Ireland, he took a leading part in the national movement of 1850-1852, and at first supported the Tenant Rights League. In May 1852 he was translated to Dublin, and soon a divergence of opinion broke out between him and the more ardent Nationalists under Archbishop MacHale. When the Irish university was started, with Newman, appointed by Cullen, at its head, the scheme was wrecked by the personal opposition to the archbishop of Dublin. As time went on, his distrust of the national movement grew deeper; and in 1853 he sternly forbade his clergy to take part publicly in politics, and for this he was denounced by the *Toblet* newspaper. His own political opinion had been best told in his own words: "For thirty years I have studied the revolution on the continent, and for nearly thirty years I have watched the Nationalist movement in Ireland. It is tainted at its sources with the revolutionary spirit. If any attempt is made to abridge the rights and liberties of the Catholic Church in Ireland, it will not be by the English government nor by a ‘No Popery’ cry in England, but by the revolutionary and irreligious Nationalists of Ireland." (Purcell’s *Life of Manning*, vol. ii. 610.) Cullen, therefore, while an ardent patriot, was consistently an opponent of Fenianism. He was made cardinal in 1866, being the first Irish cardinal. Energetic as an administrator, churches and schools rose throughout his diocese; and the excellent Mater Misericordiae Hospital and the seminary at Clonliffe are lasting memorials of his zeal. He took part in the Vatican Council as an ardent infallibilist. In 1873 he was defendant in a libel action brought against him by the Rev. R. O’Keefe, parish priest of Callan, on account of two sentences of ecclesiastical censure pronounced by the cardinal as papal delegate. The damages were laid at £10,000. Three of the four judges allowed the defence of the cardinal to be valid; it was held that the principles on which he relied for his extra-legal action as delegate was illegal under statute; and the lord chief justice decided that the plaintiff could not renounce his natural and civil liberty. After several days’ trial, during which Cullen was submitted to a very close examination, the verdict was given for the plaintiff with £1,000 damages. The cardinal died in Dublin on the 24th of October 1878. (E. T.)

CULLEN, WILLIAM (1710-1790), Scottish physician and medical teacher, was born at Hamilton, Lanarkshire, on the 1st of April 1710. He received his early education at the grammar-school of Hamilton, and he appears to have subsequently attended some classes at the university of Glasgow. He began his medical career as apprentice to John Paisley, a Glasgow surgeon, and after completing his apprenticeship he became surgeon to a merchant vessel trading between London and the West Indies. On his return he was in 1725 settled as a practitioner in the parish of Shotts, Lanarkshire, and in 1734-1736 studied medicine at Edinburgh, where he was one of the founders of the Royal Medical Society. In 1736 he began to practise in Hamilton, where he rapidly acquired a high reputation. From 1737 to 1740 William Hunter was his resident pupil, and at one time they proposed to enter into partnership. In 1740 Cullen took the degree of M.D. at Glasgow, whither he removed in 1744. During his residence at Hamilton, besides the arduous duties of medical practice, he found time to devote to the study of the natural sciences, and especially of chemistry. On coming to Glasgow he appears to have begun to lecture in connexion with the university, the medical school of which was as yet imperfectly organized. Besides the subjects of theory and practice of medicine, he lectured systematically on botany, materia medica and chemistry. His great abilities, enthusiasm and power of conveying instruction made him a successful and highly popular teacher, and his classes increased largely in numbers. At the same time he diligently pursued the practice of his profession. Chemistry was the subject which at this time seemed to demand the greatest share of his attention. He was himself a diligent investigator and experimenter, and he did much to encourage original research among his pupils, one of whom was Dr Joseph Black. In 1751 he was appointed professor of medicine, but continued to lecture on chemistry, and in 1756 he was elected joint professor of chemistry at Edinburgh along with Andrew Plummer, on whose death in the following year the sole appointment was conferred on Cullen. This chair he held for ten years—his classes always increasing in numbers. He also practised his profession as a physician with eminent success. From 1757 he delivered lectures on clinical medicine in the Royal Infirmary. This was a work for which his experience, habits of observation, and scientific training peculiarly fitted him, and in which his popularity as a teacher, no less than his power as a practical physician, became more than ever conspicuous. On the death of Charles Alston in 1766, Cullen at the request of the students undertook to finish his course of lectures on materia medica; he completed the unfinished contents, which were published in an unauthorized edition in 1771, but which he re-wrote and issued as *A Treatise on Materia Medica* in 1780.

On the death of Robert Whytt (1714-1766), the professor of the institutes of medicine, Cullen accepted the chair, at the same time resigning that of chemistry. In the same year he had been an unsuccessful candidate for the professorship of the practice of physic, but subsequently an arrangement was made between him and John Gregory, who had gained the appointment, by which they agreed to deliver alternate courses on the theory and practice of physic. This arrangement proved eminently satisfactory, but it was brought to a close by the sudden death of Gregory in 1773. Cullen was then appointed sole professor of the practice of physic, and he continued in this office till a few months before his death, which took place on the 4th of February 1790.

As a lecturer Cullen appears to have stood unrivalled in his day. His clearness of statement and power of imparting interest to the most abstruse topics were the conspicuous features of his teaching, and in his various capacities as a scientific lecturer, a physiologist, and a practical physician, he was ever surrounded with large and increasing classes of intelligent pupils, to whom his eminently suggestive mode of instruction was specially attractive. Living at the time he did, when the doctrines of the humoral pathologists were carried to an extreme extent, and witnessing the ravages which disease made on the solid structures of the body, it was not surprising that he should oppose a doctrine which adopted him to lead to a false practice and to fatal results, and which attributed more to the agency of the solids and very little to that of the fluids of the body. His chief works were *First Lines of the Practice of Physic* (1774); *Institutions of Medicine* (1770); and *Synopsis*...
CULLEN—CULM

Nosologicae Medicæ (1783), which contained his classification of diseases into four great classes—(1) Pyrexiae, or febrile diseases, as typhus fever; (2) Neuroses, or nervous diseases, as epilepsy; (3) Cachexiae, or diseases resulting from bad habit of body, as scurvy; and (4) Locales, or local diseases, ascancer.

Cullen's eldest son Robert became a Scottish judge in 1796 under the title of Lord Cullen, and was known for his powers of mimicry.

The first volume of an account of Cullen's Life, Lectures and Writings was published by Dr John Thomson in 1832, and was re-issued with the second volume (completing the work) by Drs W. Thomson and D. Craigie in 1859.

CULLEN, a royal, municipal and police burgh of Banffshire, Scotland. Pop. (1901) 1936. It is situated on Cullen Bay, \( \frac{1}{2} \) m. W. by N. of Banff and 66\(^{\circ}\) W. N.W. of Aberdeen by the Great North of Scotland railway. Deskford Burn, after a course of 8 m., enters the sea at Cullen, which it divides into two parts, Seatinw, the older, and Newtown, dating only from 1822. St Mary's, the parish church, a cruciform structure, was founded by Robert Bruce, whose second wife died at Cullen. The industries include rope and sail making, boat-building, brewing and fishing. This harbour, constructed between 1817 and 1828, though artificial, is one of the best on this coast. About 1 m. to the S. is Cullen House, a seat of the earl of Seafield, which contains some fine works of art. A mile and a half to the W. is the picturesque fishing village of Port Knockie with a deep-sea harbour, built in 1891. On the cliffs, 2 m. to the E., stand the ruins of Findlater Castle, fortified in 1455. From 1638 to 1811, when the title expired, it gave the title of earl to the Oglivies, whose name was adopted in addition to his own by Sir Lewis Alexander Grant, when he succeeded, as 5th earl of Seafield, to the surviving dignitaries. Five miles to the E. of Cullen is the thriving fishing town of Portsoy, with a small, safe harbour and a station on the Great North of Scotland railway. Besides the fisheries there is fish-curing and a distillery; and the quarrying of a pink-coloured variety of granite and of Portsoy marble is carried on. Good limestone is also found in the district. Pop. (1901) 2601.

Cullera, a seaport of eastern Spain, in the province of Valencia; on the Mediterranean Sea, at the mouth of the river Jucar, and on the northwest of the Valencia-Silla-Cullera railway. Pop. (1881) 11,947. Cullera is a walled town, containing a ruined Moorish citadel, large barracks, several churches and convents and a hospital. It occupies the Jucar valley, south of the Sierra de Zorras, a low range of hills which terminates eastward in Cape Cullera, a conspicuous headland surmounted by a lighthouse. To the south and west extends a rich agricultural district, noted for its rice. Besides farming and fishing, the inhabitants carry on a coasting trade with various Mediterranean ports. In 1903 the harbour was entered by 66 vessels of about 25,000 tons, engaged in the exportation of grain, rice and fruit, and the importation of guano. The town of Sueca (q.v.) is 4 m. W.N.W. by rail.

Cullinan, a town of the Transvaal, 36 m. by rail E. by N. of Pretoria. It grew up round the Premier diamond mine and dates from 1903, being named after T. Cullinan, the purchaser of the ground on which the mine is situated. Here was discovered in January 1905 a diamond—the largest on record—weighing 3025\(^{\circ}\) carats. This diamond was in 1907 procured by the Transvaal government to Edward VII. and was subsequently cut into stones, one of 5165 carats, the other of 309 carats, intended to ornament the sceptre and crown of England. The "chippings" yielded several smaller diamonds (see DIAMOND).

CULODDEN, a desolate tract of moorland, Inverness-shire, Scotland. It forms part of the north-east of Drumossie Muir, and is situated about 6 m. by road E. of Inverness, and \( \frac{1}{2} \) m. from Culloden Muir station on the Highland railway from Aviemore to Inverness via Daviot. It is celebrated as the scene of the battle of the 16th of April 1746 (see CUMBERLAND, WILLIAM AUGUSTUS, DUKE OF, and MURRAY, LORD GEORGE), by which the fate of the house of Stuart was decided. By Highlanders the battle is more generally described as the battle of Drumossie.

Memorial stones bearing the names of the clans engaged in the conflict were erected in 1881 at the head of each trench where the clansmen—about 1000 in number—were buried. A monument cairn, 20 ft. high, marks the chief scene of the fight, and the Cumberland Stone, a huge boulder, indicates the spot where the English commander took up his position. A mile to the north is Culloden House, which belonged to Duncan Forbes, the president of the Court of Session. The Culloden Papers, a number of historical documents ranging from 1525 to 1748, were discovered in this mansion in 1872 and published in 1875 by Duncan George Forbes. On the death of the 10th laird, the collection of Jacobite relics and works of art was sold by auction in 1875. About 1 m. to the south of the field, on the right bank of the Nairn, is the plain of Clava, containing several stone circles, monoliths, cairns and other prehistoric remains. The circles, some apparently never completed, vary in circumference from 12 yds. to 140 yds.

CULM, in geology, the name applied to a peculiar local phase of the Carboniferous system. In 1837 A. Sedgwick and R. I. Murchison classified into two divisions the dark shales, grits and impure limestones, each of which occupies a large area in Devonshire and extends into the neighbouring counties of Cornwall and Somerset. These two divisions were the Upper and Lower Culm Measures, so named from certain impure coals, locally called "culm," contained within the shales near Bideford. Subsequently, these two geologists, when prosecuting their researches in Germany and Austria, applied the same name to similar rocks which contained, amongst others, Posidonoma Becheri, common to the phase of sedimentation in both areas.

The Culm measures of the Devonshire district are folded into a broad syncline with its axis running east and west; but within this major fold the rocks have been subjected to much compression accompanied by minor folding. This circumstance, together with the apparent barrenness of the strata, has always made a correct interpretation of their position and relationships a matter of difficulty; and for long they were regarded as an abnormal expression of the Lower Carboniferous, with the uppermost beds as doubtful equivalents of the Millstone Grit of other parts of Britain. The labours of W. A. E. Usher and of G. J. Hinde and H. Fox have resulted in the differentiation of the following subdivisions in the Devonshire Culm: (1) Upper Culm Measures or Eggsford grits; (2) Middle Culm Measures, comprising the Marchord, Tiverton and Ugborough lithological types overlying the Exeter type; (3) Lower Culm, the Posidonoma limestone and shale overlying the Coddon Hill beds with radiolaria. Usher's subdivisions were introduced to satisfy the exigencies of geological mapping, but, as he pointed out, while they are necessary in some parts of the district and convenient in others, the lithological characters upon which they are founded are variable and inconsistent. More recently E. A. N. Arber (1904-1907) clearly demonstrated that no palaeontological subdivision of the Upper Culm (Middle and Upper) is possible, and that these strata, on the evidence of the fossil plants, represent the Middle Coal Measures of other parts of the country. Wheelon Hind has called attention to the probability that the Posidonoma limestone and shale may represent the Pennsile group of Lancashire, Derbyshire, &c. The Coddon Hill beds may belong to this or to a lower horizon. Thus the English Culm is an Upper Carboniferous and a Lower Carboniferous group, while in Germany, Austria and elsewhere (where it is important to bear in mind) the Culm, or "Kulm," stage is shown by its contained fossils to belong to the lower division alone.

The typical Carboniferous limestone of the Franco-Belgian area changes as it is traced towards the east and south into the sandy, shaly Culm phase, with the characteristic "Posidonia" (Posidonoma) shists. This aspect of the Culm is found in Saxony, where there are workable coals, in Bohemia, Thuringia, the Fichtelgebirge, the Harz, where the beds are traversed by mineral veins, and in Moravia and Silesia. In the last-mentioned region the thickness of the Culm formation has been estimated as

"This word is possibly connected with col, coal; distinguish "culm," the stem of a plant, Lat. culmus."

CULROSS
CULMINATION
m.
other
clerk
ready
lower.

CULMINATION
(from Lat. culmen, summit), the attainment of the highest point. In astronomy the term is given to the
passage of a heavenly body over the meridian of a place. Two
culminations take place in the course of the day, one above
and the other below the pole. The first is called the upper, the second
the lower. Either or both may occur below the horizon and
therefore be invisible.

CULMINATION
of the
prisoner at the bar, one accused of a
crime; so used, generally, of one guilty of an offence. In
origin the word is a combination of two Anglo-French legal
words, culpable, guilty, and prit or prist, i.e. prest, Old French for
prêt, ready. On the prisoner at the bar pleading “not guilty,”
the clerk of the crown answered “culpable,” and stated that he
was ready (prêt) to join issue. The words cul. prist (or pril) were
then entered on the roll as showing that issue had been joined.
When French law terms were discontinued the words were taken
as forming one word addressed to the prisoner. The formula
“Culpit, how will you be tried?” in answer to a plea of “not
guilty,” is first found in the trial for murder of the 7th earl of
Pembroke in 1678.

CULROSS (locally pronounced Coo-ros), a royal and police
burgh, Fife sheriffdom, Scotland, 63 m. W. by S. of Dunfermline and
25 m. from East Grange station on the North British railway
company's line from Dunfermline to Stirling. Pop. 348. Until 1890
it belonged to the detached county of Perthshire. Attractively
situated on a small island sloping gently to the Forth, its
placid old-world aspect is in keeping with its great antiquity.
Here St Serf carried on his missionary labours, and
church and cemetery, and here he died and was buried. For
centuries the townfolk used to celebrate his day (July 1st) by
walking in procession bearing green boughs. Kentigern, the
apostle to Cumbria and first bishop of Glasgow, was born at
Culross, his mother having been driven ashore during a tempest,
and was adopted by St Serf as his son. These religious
associations, coupled with the fertility of the soil, led to the founding
of a Cistercian abbey in 1217. Of this structure the only remains
are the western tower and the choir, which, greatly altered as
well as repaired early in the 19th century, now forms the parish
curch. It is supposed that a chapel of which some traces exist
in the east end of the church was dedicated to Kentigern. James
VI. made Culross a royal burgh in 1558. In 1608 there was
discovered in the abbey church, embalmed in a silver casket,
still preserved there, bearing his name and arms, the heart of
Edward, Lord Bruce of Kinnoul, who was killed in August 1615
near Bergen-op-Zoom in a duel with Sir Edward Sackville,
 afterwards earl of Dorset. Robert Pont (1524–1606), the
Reformer, was born at Shiresmith, or Shiresmeil, a hamlet in Culross
parish. Nearly all its old industries—the coal mines, salt
works, linen manufacture, and even the making of iron girdles for
the baking of scones—have dwindled, but its pleasant climate and
picturesqueness make it a holiday resort. Dunimarle Castle,
a handsome structure on the sea-shore, adjoins the site of the
castle where, according to tradition, Macbeth slew the wife
and children of Macduff. Culross belongs to the Stirling district
of parliamentary burghs.

CULTIVATOR, also called SCUFFIER, SCRAPPER or GRUBBER,
an agricultural implement employed in breaking up land or in
scraping it after ploughing. The first all-iron cultivator, known
as Finlayson's grubber, was a large harrow with curved teeth
carried on wheels, and was brought out about 1820. It was
designed to meet the need for some implement of intermediate
caracter between the plough and harrow, which should
stir the soil deeply and expeditiously without reversing it, and
bring the weeds unbroken to the surface. The
cultivar chief improvement has been
the imparting of
vibratory
movement and hence greater
stirring capacity to
the
tines, either by
making them
of
spring steel
or by
fitting springs to the
point of attachment of the
tines to the
framework
of
the machine.

In its
modern form the implement consists of a framework fitted
with rows of curved stems or tines, which may be raised clear of
the ground or lowered into work by means of a lever, and differ
from the harrow in that it is provided with two wheels, which
prevent the tines from embedding themselves too deeply in the
soil. The stems may be fitted either with chisel-points or with
broad shares, according as it is required to merely stir the soil
or to bring up weeds and clean the surface. In the disk cultivator
revolving disks take the place of tines. The implement is usually
provided with a seat for the driver and is drawn by horses, but
steam power is also commonly applied to it, the speed of
the operation in that case increasing its effectiveness. The method
is the same as that of steam-ploughing (see PLOUGH).

CUMAE (Gr. Κύμη), an ancient city of Campania, Italy, about
12 m. W. of Neapolis, on the W. coast of Campania, on a volcanic
eminence, overlooking the plain traversed by the Vulturno.
There are many legends as to its foundation, but even the
actual period of its colonization by the Greeks is so early (ancient
authorities give it as 1050 B.C.) that there is some doubt as to
who established it, whether Chalcidians from Euboea or Aeolians
from Cyme (Cyme), and it should probably be regarded as a joint
settlement. It was certainly, as Strabo says, the oldest of the
Greek colonies on the mainland of Italy or in Sicily. Livy tells
us (vii. 22) that the settlers first landed on Pithecusae (Ischia)
and thence transferred their position to the mainland, which
seems a probable story. We find it in 721 B.C. founding Zancle
(Messina) in Sicily jointly with Chalcis, and it extended its
power gradually over the coast of the Gulf of Puteoli and the
harbours of the promontory of Misenum. Puteoli itself under
the name Dicaearchia was probably founded by Cumae. In the
7th century, according to the legends, Parthenope, whither the
demos of Cumae had taken refuge after an unsuccessful rising
against the aristocracy, was attacked by the latter and destroyed,
but soon rebuilt under the name of Neapolis (New City, the
present Naples). The most fertile portion of the Campanian
plain was also under its dominion; the name "ossa Graeca"
still lingered on in 205 B.C. to testify to its ancient limits.
Cumae was now at the height of its power, and many fine coins testify
to its prosperity. In 224 B.C. it was the object of a joint attack
by the Etruscans of Capua, the Daunians of the district of Nola,
and the Aurunci of the Mons Massicus. A brilliant victory was,
however, won in the hilly district outside the town, largely owing

1 From Late Lat. cultivare, through cultus, from colere, to till,
cultivate; whence cultus, worship, form of religion, cult.
2 Mons Megg., however (Corpus Inscr. Latin. x., Berlin, 1883,
p. 170), rightly throws considerable doubt on the existence of
Parthenope and even of Palaope, of which there is some
mention in Roman annals; under both he inclined to trace Cumae
itself.
to the bravery of Aristodemus, who then led a force to the relief of Aricia, which was being attacked by the Etruscans, and, returning at the head of his victorious army, overthrew the aristocracy and made himself tyrant, but was ultimately murdered by the aristocrats. These were unable to repel a renewed Etruscan attack without the help of Hiero of Syracuse, who in the battle of Cumae of 474 B.C. drove the Etruscan fleet from the sea, and broke their power in Campania.

The Samnites finally destroyed the Etruscan supremacy by the capture of Capua in the latter half of the 5th century (see Capua; CAMPANIA), and the Greeks of Cumae were overthrown by the same invasion, either in 420 B.C. (Livy iv. 44) or in 421 (Diodor. Sic. xii. 76), if his statement is drawn from Greek sources, if it is to be dated by the Roman consuls to whose year he ascribes it. This catastrophe brought to an end the beautiful series of Greek coins from the town (B. V. Head, Historia Numorum, p. 31), and Oscar became its language, though in many respects the Greek character of the town survived (Strabo v. 4. 3, and the other references given by R. S. Conway, Italic Dialects, p. 84). One or two inscriptions in Oscar survive (id. ib. 88-92), one of which is a Livia or herlidal dedication.

The date of the general disuse of Oscar in the town appears to be fixed about 180 B.C. by the request (Livy xiv. 50) which the Cumaeans addressed to Rome that they might be allowed to use Latin for public purposes. Cumae now ceased to have any independent history. It came to Rome in 343 (or 340) as Capua did, obtained the civitas sine suffragio and was governed after 318 by the praefecti Capuae Cumanum.

(R. S. C.)

In the Hannibalic wars it remained faithful to Rome. It probably acquired civil rights in the Social War and remained a municipium until Augustus established a colony here. Under the empire it is spoken of as a quiet country town, in contrast to the gay and luxurious Baiae, which, however, with the lacus Imerius and lacus Lucernus, formed a part of its territory. Cicero's villa on the east bank of the latter, for example, which he called the Academia, was also known as Cumanum. In the Gothic wars the aeropolis of Cumae was, except Naples, the only fortified town in Campania, and it retained its military importance until it was destroyed by the Neapolitans in 1205, since which time it has been deserted.

The acropolis hill (269 ft. above sea-level), a mass of trachyte which has broken through the surrounding tufa, lies hardly 100 yds. from the low sandy shore. It is traversed by caves, which are at three different levels with many branches. Some of them may belong to a remote date, while others may be quarries, but they have not been thoroughly investigated. They are famous in legend as the seat of the oracle of the Cumaean Sibyl.

The acropolis has only one approach, on the south-east; on all other sides it falls away steeply. Remains of fortifications of all ages run round the edge of the hill; some of the original Greek work, in finely hewn rectangular tufa blocks, exists on the east. The medieval line follows the ancient, except on the N.E., where it takes in a larger area.

Within the acropolis stood the temple of Apollo, erected, according to tradition, by Daedalus himself, the remains of which, restored in Roman times, were discovered in 1817, on the eastern and lower summit. On the higher western summit stood another temple, excavated in 1792, but now covered up again. This may be that of the Olympic Zeus (Livy xvii. 23).

There are also various remains of buildings of the Imperial period, and these are far more frequent on the site of the lower town (now occupied by the city of Ocer) near the isthmus of Cumae, than on the south. The line of the city walls can be traced both on the E. and on the W., though the remains on the E. are insignificant, and on the W. (the seaward side) only the scarping of the hill remains. To the S. of the town, just outside the wall, is the amphitheatre. To the N. of it is the point where the roads from Liternum (the Via Domitiana running along the sandy coast), Capua (a branch of the Via Campana), Misenum and Puteoli meet. The last passes through the Arco Felice, an arch of brick-faced concrete 63 ft. high which spans a cutting through the Monte Grillo, made by Domitian to shorten the course of the road, which had hitherto run farther north. The Grotto della Pala leads to the shores of Avnemus. On the E. side of Cumae are considerable remains of the Roman period, among them those of the temple of Demeter, as restored by the family of the Luccei.

The cemeteries of Cumae extended on all sides of the ancient city, except towards the sea, but the most important lay on the north, between this temple and the Lago di Licola. Excavations during the 19th century in Greek, Samnite and Roman graves have produced many important objects, now in the various museums of Europe, but especially at Naples. Recent discoveries in this necropolis (including that of a circular archaic tomb with a conical roof) have led to considerable discussion as to the true date of the foundation of Cumae, and have made it clear that, in any case, a pre-Hellenic indigenous settlement existed here—a result of great importance.

CUMANÁ, a city and port of Venezuela, capital of the state of Bermudez, situated on the Manzanares river about 1 m. above its mouth, 52 ft. above sea-level and 180 m. E. of Caracas. It is the oldest existing European settlement on the South American continent, having been founded by Diego Castellón in 1523 under the name of Nueva Toledo. The city was almost totally destroyed by an earthquake in 1766, and again in 1797. Slight shocks are very frequent, some of them severe enough to cause considerable damage to the buildings. The mean annual temperature is 83° F. and the climate is enervating. In colonial times the city was rich and prosperous and enjoyed a lucrative trade with the mother country; its population at that time being estimated at 30,000, but much of its prosperity has disappeared, and its population is now estimated at 10,000. Excellent fruits are produced in its vicinity, and its exports include cacao, coffee, sugar, hides, tobacco and sundry products in small quantities. A tramway connects the city with its port at the mouth of the Manzanares.

CUMBERLAND, DUKES AND EARLS OF. The earldom of Cumberland was held by the family of Clifford (q.v.) from 1525 to 1643, when it became extinct by the death of Henry, the 5th earl. The 1st earl of Cumberland was Henry, 11th Lord Clifford (1493-1542), a son of Henry, 10th Lord Clifford (c. 1454-1532). Created an earl by Henry VIII. in 1525, Henry remained loyal during the great rising in the north of England in 1536, and died on the 22nd of April 1542. His son and successor, Henry, the 2nd earl (c. 1517-1579), married Eleanor (d. 1547), a daughter of Charles Brandon, duke of Suffolk, and Mary, daughter of King Henry VII; he had the tastes of a scholar rather than a soldier, and died early in 1570. By his first wife, Eleanor, he left an only daughter Margaret (1540-1596), who married Henry Stanley, 4th earl of Derby, and who in 1557 was regarded by many as the rightful heiress to the English throne. By his second wife he left two sons and a daughter; his elder son George succeeding to the earldom in 1570, and his younger son Francis succeeding his brother in 1605. George, 3rd earl of Cumberland (1558-1605), was born on the 8th of August 1558, and married Margaret (c. 1560-1616), daughter of his guardian, Francis, 2nd earl of Bedford. Although interested in mathematics and geography he passed his early years in dissipation and extravagance; then he took to the sea, commanded the "Bonaventure" against the Spanish Armada, and from this time until his death he was engaged in fitting out and leading plundering expeditions, some of which, especially the one undertaken in 1589, gained a large amount of booty. The earl left no sons, and his barony was claimed by his only daughter Anne (1590-1676), the wife successively of Richard Sackville, 3rd earl of Dorset, and of Philip Herbert, 4th earl of Pembroke and Montgomery; while his earldom was inherited by his brother Francis (1559-1641). A long law-suit between the new earl and the countess Anne over the possession of the
family estates was settled in 1617. The 5th earl was Francis's only son Henry (1591-1661), who was born on the 28th of February 1591, and was educated at Christ Church, Oxford.

He was a supporter of Charles I. during his two short wars with the Scots, and also during the Civil War until his death on the 11th of December 1643. He left no sons; his heirloom became extinct; his new barony of Clifford, created in 1628, passed to his daughter Elizabeth (1618-1661), wife of Richard Boyle, earl of Cork and Burlington; and the Cumberland estates to his cousin Anne, countess of Dorset and Pembroke.

In 1644 the English title of duke of Cumberland was created in favour of Rupert, son of Frederick V, elector palatine of the Rhine, and nephew of Charles I. Having lapsed on Rupert's death without legitimate issue in 1682, it was created again in 1689 to give an English title to George, prince of Denmark, who had married the lady who afterwards became Queen Anne. It again became extinct when George died in 1708, but was revived in 1726 in favour of William Augustus, third son of George II. As this was never married the title passed on his death in 1765, but was revived in the following year in favour of Henry Frederick (1745-1790), son of Frederick, prince of Wales, and brother of George III. Having again become extinct on Henry Frederick's death, the title of duke of Cumberland was created for the fifth time in favour of Ernest Augustus, who was made duke of Cumberland and Teviotdale in 1790. In 1837 Ernest (g.v.) became king of Hanover, and on his death in 1851 the title descended with the kingdom of Hanover to his son King George V (g.v.), and on George's death in 1878 to his grandson Ernest Augustus (b. 1843). In 1866 Hanover was annexed by Prussia, but King George died without renouncing his rights. His son Ernest, while maintaining his claim to the kingdom of Hanover, is generally known by his title of duke of Cumberland.

CUMBERLAND, RICHARD (1632-1718), English philosopher and bishop of Peterborough, the son of a citizen of London, was born in the parish of St Ann, near Aldgate, in Christ Church college, Cambridge, where he obtained a fellowship. He took the degree of B.A. in 1653; and, having proceeded M.A. in 1656, was next year incorporated to the same degree in the university of Oxford. For some time he studied medicine; and although he did not adhere to this profession, he retained his knowledge of anatomy and medicine. He took the degree of B.D. in 1663 and that of D.D. in 1680. Among his contemporaries and intimate friends were Dr Hezekiah Burton, Sir Samuel Morland, who was distinguished as a mathematician, Sir Orlando Bridgeman, who became keeper of the great seal, and Samuel Pepys. To this academical connexion he appears to have been in a great measure indebted for his advancement in the church. When Bridgeman was appointed lord keeper, he nominated Cumberland and Burton as his chaplains, nor did he afterwards neglect the interest of either. Cumberland's first preferment, bestowed upon him in 1658 by Sir John Northwood, was the rectory of Allington in Northamptonshire. In 1661 he was appointed one of the twelve preachers of the university. The lord keeper, who obtained his office in 1667, invited him to London, and soon afterwards bestowed upon him the rectory of Allhallows at Stamford, where he acquired new credit by the fidelity with which he discharged his duties. In addition to his ordinary work he undertook the weekly lecture. This labour he constantly performed, and in the meantime found leisure to prosecute his scientific and philosophical studies.

At the age of forty he published his earliest work, entitled De legibus naturae disquisitio philosophica, in qua earum formam, summa copia, ordo, promulgatio, et obligatione et rerum natura investigatur; quin etiam elementa philosophiae Hobbianae, cum moralis tam civilis, consideratur et refutatur (London, 1671). It is dedicated to Sir Orlando Bridgeman, and is prefixed by an "Alloquio ad Lectorum," contributed by Dr Burton. It appeared during the same year as Pufendorf's De jure naturae et gentium, and was highly commended in a subsequent publication by Pufendorf, whose approbation must have had the effect of making it known on the continent. Having thus established a solid reputation, Cumberland next prepared a work on a very different subject—An Essay towards the Recovery of the Jewish Measures and Weights, comprehending their Manners; by help of ancient standards, compared with ours of England: useful also to state many of those of the Greeks and Romans, and the Eastern Nations (London, 1806). This work, dedicated to Pepys, obtained a copious notice from Le Clerc, and was translated into French.

About this period he was depressed by apprehensions respecting the growth of Popery; but his fears were dispelled by the Revolution, which brought along with it another material change in his circumstances. One day in 1691 he went, according to his custom on a post-day, to read the newspaper at a coffee-house in Stamford, and there, to his surprise, he read that the king had nominated him to the bishopric of Peterborough. The bishop elect was scarcely known at court, and he had resorted to none of the usual methods of advancing his temporal interest.

"Being then sixty years old," says his great-grandson, "he was with difficulty persuaded to accept the offer, when it came to him from authority. The persuasion of his friends, particularly Sir Orlando Bridgeman, at length overcame his repugnance; and to that see, though very moderately endowed, he for ever after devoted himself, and resisted every offer of translation, though repeatedly pressed to make another. He resolved to marry his friends as pressed an exchange upon him he was accustomed to reply, that Peterborough was his first espoused, and should be his only one."

He discharged his new duties with energy and kept up his episcopal visitations till his eightieth year. His charges to the clergy are described as plain and unambitious, the earnest breathings of a pious mind. When Dr Wilkins (David Wilkie) published the New Testament in Coptic he presented a copy to the bishop, who began to study the language at the age of eighty-three.

"At this age," says his chaplain, "he mastered the language, and went through great part of this version, and would often give me excellent hints and remarks, as he proceeded in it."

He died in 1718, in the eighty-seventh year of his age; he was found sitting in his library, in the attitude of one asleep, and with a book in his hand.1 His great-grandson was Richard Cumberland, the dramatist.

Bishop Cumberland was distinguished by his gentleness and humility. He could not be roused to anger, and spent his days in unbroken serenity. The basis of his ethical theory is Benevolence, and is the natural outcome of his temperament. He was a man of a sound understanding, improved by extensive learning, and left behind him several monuments of his talents and industry. His favourite motto was that a man had better "wear out than rust out."

The philosophy of Cumberland is expounded in the treatise De legibus naturae. The merits of the work are almost confined to its speculative theories; its style is destitute of strength and grace, and its reasoning is diffuse and unmethodical. Its main design is to combat the principles which Hobbes had promulgated in his "Elements of man, the nature of morality, and the way to prevent the degeneracy of man; that force is not the source of personal obligation to moral conduct or the foundation of social rights, and that the state of nature is not a state of war. The views of Hobbes seem

1The care of his posthumous publications devolved upon his domestic chaplain and son-in-law, Squier Payne, who soon after the bishop's death edited "Sanchoniaton's Phoenician History, translated from the first book of Eusebius, De praeparatione evangelica: with a continuation of Sanchoniaton's history of Erotherosines Cyrenaeus's Cynemon, English Dialect with the first Odes; and these authors are illustrated with many historical and chronological remarks, proving them to contain a series of Phoenician and Egyptian chronology, from the first man to the first Olympiad, agreeable to the horizon of the accounts" (London, 1720). The preface contains an account of the life, character and writings of the author, which was likewise published in a separate form, and exhibits a pleasing picture of his happy old age. A German translation appeared under the title of Cumberland's phämiatische Historie der Sanchoniaton's, ubersetzt von J ohn Philip, Cassel (Magdeburg, 1755). The sequel to the work was likewise published by Payne—Origines gentium antiquissimae: or Attempts for discovering the Times of the First Planting of Nations: in several Tracts (London, 1724).
CUMBERLAND, BISHOP

621
to Cumberland utterly subversive of religion, morality and civil society, and he endeavours, as a rule, to establish directly antagonistic propositions. He refrains, however, from denunciation, and is a fair opponent up to the measure of his insight.

Laws of nature are defined by him as "immutably true propositions regulative of voluntary actions as to the choice of good and the avoidance of evil, and which carry with them an obligation to outward acts of obedience, even apart from civil laws and from any considerations of compacts constituting government." This definition, he says, will be admitted by all parties. Some deny that such laws exist, but they will grant that this is what ought to be understood by them. There is thus common ground for the two opposing schools of moralists to join issue. The question between them is, Do such laws exist or do they not? In reasoning thus Cumberland obviously forgot what the position maintained by his principal antagonist really was. Hobbes must have refused to accept the definition proposed. He did not deny that there were laws of nature, laws antecedent to government, laws even in a sense eternal and immutate. The virtues as means to happiness seemed to him to be such laws. He expressly denied, however, that "they carry with them an obligation to outward acts of obedience, even apart from civil laws and from any consideration of compacts constituting governments." And many besides Hobbes must have felt dissatisfied with the definition. It is ambiguous and obscure. In what sense is a law of nature a "proposition"? Is it as the expression of a constant relation among facts, or as it is the expression of a divine commandment? A proposition is never in itself an ultimate fact although it may be the statement of such a fact. And in what sense is a law of nature an "immutably true" proposition? Is it so because men always and everywhere accept and act on it, or merely because they always and everywhere ought to accept and act on it? The definition, in fact, explains nothing.

The existence of such laws may, according to Cumberland, be established in two ways. The inquirer may start either from effects or from causes. The former method had been taken by Grotius, Robert Sharrock (1630–1684) and John Selden. They had sought to prove that there were universal truths, entitled to be called laws of nature, from the concurrence of the testimonies of many men, peoples and ages, and through generalizing the operations of certain active principles. Cumberland admits this method to be valid, but he prefers the other, that from causes to effects, as showing more convincingly that the laws of nature carry with them a divine obligation. It shows not only that these laws are universal, but that they were intended as such; that man has been constituted as he is in order that they might be. In the prosecution of this method he expressly declares to have recourse to what he calls "the short and easy expedient of the Platonists," the assumption of innate ideas of the laws of nature. He thinks it ill-advised to build the doctrines of natural religion and morality on a hypothesis which many philosophers, both Gentile and Christian, had rejected, and which could not be proved against Epicureans, the principal impugners of the existence of laws of nature. He cannot assume, he says, that such ideas existed from eternity in the divine mind, but must start from the data of sense and experience, and thence by search into the nature of things discover their laws. It is the inherent nature that we can rise to nature's God. His attributes are not to be known by direct intuition. He, therefore, held that the ground taken up by the Cambridge Platonists could not be maintained against Hobbes. His sympathies, however, were all on their side, and he would do nothing to diminish their chances of success. He would not even oppose the doctrine of innate ideas, because it looked with a friendly eye upon piety and morality. He granted that it might, perhaps, be the case that ideas were both born with us and afterwards impressed upon us from without.

Cumberland's ethical theory (see EPICS) is summed up in his principle of universal Benevolence, the one source of moral good. "No action can be morally good which does not in its own nature contribute somewhat to the happiness of men." The theory is important in comparison (1) with that of Hobbes, and (2) with modern utilitarianism.

1. Cumberland's Benevolence is, deliberately, the precise antithesis to the Egoism of Hobbes. To this fact it owes its existence and also its extravagance. Feeling that the most forcible method of attacking Hobbes was to assert the opposite in the same form, he maintained that the whole-hearted pursuit of the good of all contributes to the good of each and brings personal happiness; that the opposite process involves misery to individuals including the self. If, then, Hobbes went to the one extreme of postulating selfishness as the sole motive of human action, Cumberland was equally extravagant as regards Benevolence. The testimony of history shows, prima facie at least, that both motives have operated throughout, and just as self-interest has been increasingly modified by conscious benevolence, so benevolence alone does not explain all personal virtue nor love to God. But it is essential to notice that Cumberland never appealed to the evidence of history, although he believed that the law of universal benevolence had been accepted by all nations and generations, and he carefully abjures from arguments founded on revealed religion, to establish the principles of moral right on nature as a basis. His method was the deduction of the propriety of certain actions from the consideration of the character and position of rational agents in the universe. He argues that all that we see in nature is framed so as to avoid and reject what is dangerous to the integrity of its constitution; that the human race would be an anomaly in the world had it not for end its conservation in its best estate; that benevolence of all to all is what in a rational view of the creation is alone accordant with its general plan; that various peculiarities of man's body indicate that he has been made to co-operate with his fellow men and to maintain society; and that certain faculties of his mind show the common good to be more essentially connected with his perfection than any pursuit of private advantage. The whole course of his reasoning proceeds on, and is pervaded by, the principle of final causes.

2. To the question, What is the foundation of rectitude?, he replies, the greatest good of the universe of rational beings. He may be regarded as the founder of English utilitarianism, but his utilitarianism is distinct from what is known as the selfish system; it goes to the contrary extreme, by almost absorbing individual in universal good. Nor does it look merely to the lower pleasures, the pleasures of sense, for the constituents of good, but rises above them to include especially what tends to perfect, strengthen and expand our true nature. Existence and the extension of our powers of body and mind are held to be good for their own sakes without respect to enjoyment. Cumberland's views on this point were long abandoned by utilitarians as destroying the homogeneity and self-consistency of their theory; but J. S. Mill and some recent writers have reproduced them as necessary to its defence against charges not less serious than even inconsistency.

The answer which Cumberland gives to the question, Whence comes our obligation to observe the laws of nature?, is that happiness flows from obedience, and misery from disobedience to them, not as the mere results of a blind necessity, but as the necessary effects of the divine will. Reward and punishment, supplemented by future retribution, are, in his view, the foundations of the laws of nature, the sources of our obligation to obey them. To the other great ethical question, How are moral distinctions apprehended?, he replies that it is by means of right reason. But by right reason he means merely the power of rising to general laws of nature from particular facts of experience. It is no peculiar faculty or distinctive function of mind; it involves no original element of cognition; it begins with sense and experience; it is gradually generated and wholly derivative. This doctrine lies only in germ in Cumberland, but will be found in full flower in Hartley, Mackintosh and later associationists.

BIBLIOGRAPHY.—Editions of the De legibus naturae (Lübeck, 1683 and 1694; English versions by John Maxwell, prebendary of
CUMBERLAND, RICHARD (1732-1811), English dramatist, was born in the master's lodge of Trinity College, Cambridge, on the 10th of February 1732. He was the great-grandson of the bishop of Peterborough; and his father, Dr Denison Cumberland, became successively bishop of Clonfert and of Kilmore. His mother was Joanna, the youngest daughter of the great scholar Richard Bentley, and the heroine of John Byrom's once popular little elegy, Colin and Phoebe. Of great mastery of Trinity his grandson has left a kindly account; he afterwards collected all the pamphlets bearing on the Letters of Phalaris controversy, and piously defended the reputation of his ancestor in his Letter to Bishop Lowth, who had called Bentley "aut caprimulgus aut fossor." Cumberland was in his seventh year sent to the grammar-school at Bury St Edmunds, and he relates how, on the head-master Arthur Kinman undertaking, in conversation with Bentley, to make the grandson as good a scholar as the grandfather himself, the latter retorted: "Pshaw, Arthur, how can that be, when I have forgot more than thou ever knewest?" Bentley died during his grandson's Bury school-days; and in 1744 the boy, who, while rising to the head of his school, had already begun to "try his strength in several slight attempts towards the drama," was removed to Westminster, then at the height of its reputation under Dr Nichols. Among his schoolfellows here were Warren Hastings, George Colman (the elder), Lloyd, and (though he does not mention them as such) Churchill and Cowper. From Westminster Cumberland passed, in his fourteenth year, to Trinity College, Cambridge, where in 1750 he took his degree as tenth wrangler. His account of his degree examination, as well as that for a fellowship at his college, part of which he underwent in the "judges' chamber," where he was born, is curious; he was by virtue of an alteration in the statutes elected to his fellowship in the second year of his degree.

Meanwhile his projects of work as a classical scholar had been interspersed with attempts at imitating Spenser—whom, by his mother's advice, he "laid upon the shelf"—and a dramatic effort (unprinted) on the model of Mason's Elfrida, called Caractacus. He had just begun to read for his fellowship, when he was offered the post of private secretary by the earl of Halifax, first lord of trade and plantations in the duke of Newcastle's ministry. His family persuaded him to accept the office, to which he returned after his election as fellow. It left him abundant leisure for literary pursuits, and included the writing of a poem in blank verse on India. He resigned his Trinity fellowship on his marriage—in 1759—to his cousin Elizabeth Ridge, to whom he had paid his addresses on receiving through Lord Halifax "a small establishment as crown-agent for Nova Scotia." In 1761 he accompanied his patron (who had been appointed lord-lieutenant) to Ireland as Ulster secretary; and in acknowledgment of his services was afterwards offered a baronetcy. By declining this he thinks he gave offence; at all events, when in 1762 Halifax became secretary of state, Cumberland in vain applied for the post of under-secretary, and could only obtain the clerkship of reports at the Board of Trade under Lord Hillsborough. While he takes some credit to himself for his incorruptibility when in Ireland, he showed zeal for his friend and secured a bishopric for his father. On the accession to office of Lord George Germaine (Sackville) in 1775, Cumberland was appointed secretary to the Board of Trade and Plantations, which post he held till the abolition of that board in 1782 by Burke's economical reform. Before this event he had, in 1780, been sent on a confidential mission to Spain, to negotiate a separate treaty of peace with that power; but though he was well received by King Charles III, and his minister Floridablanca, the question of Gibraltar was a supposed obstacle to his mission, and the Gordon riots at home a most untoward occurrence. He was recalled in 1781, and was refused repayment of the expenses he had incurred, towards which only £1000 had been advanced to him. He had himself lent £4500 out of pocket: in vain, he says, "I wearied the door of Lord North till his very servants drove me from it"; his memorial remained unread or unnoticed either by the prime minister or by secretary Robinson, through whom the original promise had been made. Soon after this experience he lost his office, and had to retire on a compensation allowance of less than half-pay. He now took up his residence at Tunbridge Wells; but during his last years he mostly lived in London, where he died on the 7th of May 1811. He was buried in Westminster Abbey, a short oration being pronounced on this occasion by his friend Dean Vincent.

Cumberland's numerous literary productions are spread over the whole of his long life; but it is only by his contributions to the drama, and perhaps by his Memoirs, that he is likely to be remembered. The collection of essays and other pieces entitled The Observer (1785), afterwards republished together with a translation of The Clouds, found a place among The British Essayists. For the accounts given in The Observer of the Greek writers, especially the comic poets, Cumberland availed himself of Bentley's MSS. and annotated books in his possession; his translations from the Greek fragments, which are not elegant but lack closeness, are republished in James Bailey's Comitia Graecorum (part i., 1840) and Hermesianacis, Archi-Iochi, et Pratinca fragmenta. Cumberland further produced Anecdotes of Eminent Painters in Spain (1782 and 1787); a Catalogue of the King of Spain's Paintings (1787); two novels—Arundel (1789), a story in letters, and Henry (1793), a "diluted comedy" on the construction and polishing of which he seems to have expended great care; a religious epic, Catuvry, or the Druid (1750); his last publication was a poetical entitled Retrospection. He is said to have proposed to have joined Sir James Bland Burges in an epic, the Exodiad (1807), and in John de Lancaster, a novel. Besides these he wrote the Letter to the Bishop of Oxford in vindication of Bentley (1767); another to the Bishop of Llandaff (Richard Watson) on his proposal for equalizing the revenues of the Established Church (1783); a Character of the late Lord Sackville (1785), whom in his Memoirs he vindicates from the stigma of cowardice; and an anonymous pamphlet, Curtius rescued from the Gulf, against the redoubtable Dr Parr. He was also the author of a version of fifty of the Psalms of David; of a tract on the evidences of Christianity; and of other religious exercises in prose and verse, the former including "as many sermons as would make a large volume, some of which have been delivered from the pulpit." Lastly, he edited, in 1809, a short-lived critical journal called The London Review, intended to be a rival to the Quarterly, with signed articles.

Cumberland's Memoirs, which he began at the close of 1804, and concluded in September 1805, were published in 1806, and a supplement was added in 1807. This narrative, which includes a long account of his Spanish mission, contains some interesting reminiscences of several persons of note—more especially Bubb Dodington, Single-Speech Hamilton, and Lord George Sackville among politicians, and of Garrick, Foote and Goldsmith; but the accuracy of some of the anecdotes concerning the last-named is not beyond suspicion. The book exhibits its author as an amiable egotist, careful of his own reputation, given to prolixity and undistinguished by wit, but a good observer of men and manners. The uneasy self-absorption which Sheridan immortalized in the character of Sir Fretful Puglasy in The Critic is apparent enough in this autobiography, but presents itself there in no offensive form. The incidental criticisms of actors have been justly praised.

Cumberland was hardly warranted in the conjecture that no English author had yet equalled his list of dramas in point of number; but his plays, published and unpublished, have been
CUMBERLAND, DUKE OF

computed to amount to fifty-four. About 35 of these are regular plays, to which have been added a operas and a farce; and about half of the whole list are comedies. The best known of them belong to what he was pleased to term "legitimate comedy," and to that species of it known as "sentimental." The essential characteristic of these plays is the combination of plots of domestic interest with the rhetorical enforcement of moral precepts, and with such small comic humour as the author possesses. These comedies are primarily, to borrow Cumberland’s own phraseology, designed as “attempts upon the heart.”

He takes great credit to himself for weaving his plays out of “homy stuff, right British druggie,” and for eschewing “the vile refuse of the Gallic stage”; on the other hand, he borrowed from the sentimental fiction of his own country, including Richardson, Fielding and Sterne. The favourite theme of his plays is virtue in distress or danger, but safe of its reward in the fifth act; their most constant characters are men of feeling and young ladies who are either prudes or coquettes. Cumberland’s comic power—such as it was—lay in the invention of comic characters taken from the “outskirts of the empire,” and professedly intended to vindicate from English prejudice the good elements of French spirit and temper.

For the rest, patriotic sentiment liberally asserts itself by the side of general morality. If Cumberland’s dialogue lacks brilliance and his characters reality, the construction of the plots is as a rule, skilful, and the situations are contrived with what Cumberland indisputably possessed—a thorough insight into the secrets of theatrical effect. It should be added that, though Cumberland’s sentimentality is often wearisome, his morality is generally sound; that if he was without the genius requisite for elevating the national drama, he did his best to keep it pure and sweet; and that if he borrowed much, as he undoubtedly did, it was not the vicious attractions of other dramatists of which he was the plagiarist.

His début as a dramatic author was made with a tragedy, The Banishment of Cicerio, published in 1761 after its rejection by Garrick; this was followed in 1765 by a musical drama, The Summer’s Tale, subsequently compressed into an afterpiece Amelia (1768). Cumberland first essayed sentimental comedy in The Brothers (1759). The theme of this comedy is inspired by Fielding’s Tom Jones; its main characteristics are the old man Captain Irondyes, and the benpecked husband Sir Benjamin Dove, whose progress to self-assertion is genuinely comic, though not altogether original. Horace Walpole said that it acted well, but read ill, though he could distinguish in it “strokes of Mr Bentley.” The epilogue paid a compliment to Garrick, who helped the production of Cumberland’s second comedy The West-Indian (1771). The hero of this comedy, which probably owes much to the suggestion of Garrick, is a young scapegrace fresh from the tropics, “with rum and sugar enough belonging to him to make all the water in the Thames into punch,”—a libertine with generous instincts, which in the end prevail. This early example of the modern drame was received with the utmost favour; it was afterwards translated into German by Boden, and Goethe acted in it at the Weimar court.

The Fashionable Lover (1772) is a sentimental comedy of the most pronounced type. The Choleric Man (1774), founded on the Adelphi of Terence, is of a similar type, the comic element rather predominant, but philanderesses of the West-Indian type are by a virtuous lawyer called Manlove. Among his later comedies may be mentioned The Natural Son (1783), in which Major O’Flaherty who had already figured in The West-Indian, makes his reappearance; The Impostors (1780), a comedy of intrigue; The Box Lobby Challenge (1794), a protracted farce; The Jew (1794), a serious play, highly effective when the character of Sheva was played by the great German actor Theodor Döring; The Wheel of Fortune (1795), in which John Kemble found a celebrated part in the misanthropist Penruddoc, who cannot forget but learns to forgive (a character declared by Kotzebue to have been stolen from his Menchenkass and Renne), while the lawyer Timothy Weasel was made comic by Richard Suet; First Love (1795); The Last of the Family (1795); False Impressions (1797); The Sailor’s Daughter (1804); and a Hint to Husbands (1806), which, unlike the rest, is in blank verse. The other works published during his lifetime include his autograph Note To Hand (1774), a farce; the songs of his musical comedy, The Widow of Delphi (1780); his tragedies of The Battle of Hastings (1778); and The Carmelite (1784), a romantic domestic drama in blank verse, in the style of Home’s Douglas, furnishing some effective scenes for Mrs Siddons and John Kemble as mother and son; and the domestic drama (in prose) of The Mysterious Husband (1783). His posthumously printed plays (published in 2 vols. in 1813) include the comedies of The Walloons (acted in 1782); The Passive Husband (acted as A Word for Nature, 1798); The Eccentric Lover (acted 1798); and Lovers’ Resolutions (once acted in 1802); the serious quasi-historic drama Conjunction; the drama Don Pedro (acted 1796); and the tragedies of Acanor (acted as The Arab, 1785); Torrendal; The Sibyl, or The Elder Brubis (afterwards amalgamated with other plays on the subject into a very successful tragedy for Edmund Kean by Payne); Tiberius in Capreae; and The False Demetrius (on a theme which attracted Schiller). Cumberland translated the Clouds of Etruria (1797), and altered for the stage Shakespeare’s Timon of Athens for Lord Massey’s The Bondman and The Duke of Milan (both 1797).

In 1806–1807 appeared Memoirs of R. Cumberland, written by himself. Cumberland’s novel, Henry, was printed in Ballantyne’s Novelist’s Library (1821), with a prefatory notice of the author by Sir Walter Scott. A so-called Critical Examination of Cumberland’s works and a memoir of the author, based on his autobiography, with the addition of some more or less feeble criticisms, by William Madforf, appeared in 1812. An excellent account of Cumberland is included in “George Paston’s” Little Memoirs of the Eighteenth Century (1901). Hettner well characterizes Cumberland’s position in the history of the English drama in Literaturgesch. d. 18. Jahrhunderts (2nd ed., 1865). l. 520. Cumberland’s portrait by Romney (whose talent he was one of the first to encourage) is in the National Portrait Gallery.

CUMBERLAND, WILLIAM AUGUSTUS, DUKE OF (1721–1765), son of King George II. and Queen Caroline, was born on the 15th of April 1721, and when five years of age was created duke of Cumberland. His education was well attended to, and his courage and capacity in outdoor exercises were notable from his early years. He was intended by the king and queen to succeed the future George III. as a captain; and in 1740 he sailed as a volunteer in the fleet under the command of Lord Norris, but he quickly became dissatisfied with the navy, and early in 1742 he began a military career. In December 1742 he was made a major-general, and in the following year he first saw active service in Germany. George II. and the “martial boy” shared in the glory of Dettingen (June 27), and Cumberland, who was wounded in the action, displayed an energy and valour, the report of which in England founded his military popularity. After the battle he was made lieutenant-general. In 1745, having been made captain-general of the British land forces at home and in the field, the duke was again in Flanders as commander-in-chief of the allied British, Hanoverian, Austrian and Dutch troops. Advancing to the relief of Tournay, which was besieged by Marshal Saxe, he engaged that great general in the battle of Fontenoy (q.v.) on the 11th of May. It cannot now be doubted that, had the duke been supported by the allies in his marvellously courageous attack on the superior positions of the French army, he would not have been recorded as a defeat to the British arms. He himself was in the midst of the heroic column which penetrated the French centre, and his conduct of the inevitable retreat was unusually cool and skilful.

Notwithstanding the severity of his discipline, the young duke had the power to inspire his men with a strong attachment to his person and a very lively esprit de corps. As a general his courage and resolution were not sufficiently tempered with sagacity and tact; but he displayed an energy and power in military affairs which pointed him out to the British people as the one commander upon whom they could rely to put a decisive stop to the successful career of Prince Charles Edward in the rebellion of 1745–1746. John (Earl) Ligonier wrote of him at this time: "Ou je suis fort trompé ou il se forme là un grand capitaine."
He was recalled from Flanders, and immediately proceeded with his preparations for quelling the insurrection. He joined the midland army under Sir John Ligonier, and was at once in pursuit of his swift-footed foe. But the retreat of Charles Edward from Derby disconcerted his plans; and it was not till they had reached Penrith, and the advanced portion of his army had been repulsed on Clifton Moor, that he became aware how hopeless an attempt to overtake the retreating Highlanders would then be. Carlisle having been retaken, he retired to London, till the news of the defeat of Hawley at Falkirk roused again the fears of the English people, and centered the hopes of Britain on the royal duke. He was appointed commander of the forces in Scotland.

Having arrived in Edinburgh on the 30th of January 1746, he at once proceeded in search of the young Pretender. He diverged, however, to Aberdeen, where he employed his time in training the well-equipped forces now under his command for the peculiar nature of the warfare in which they were about to engage. What the old and experienced generals of his time had failed to accomplish or even to understand, the young duke of Cumberland, as yet only twenty-four years of age, effected with simplicity and ease. He prepared to dispose his army so as to withstand with firmness that onslaught on which all Highland successes depended; and he reorganized the forces and restored their discipline and self-confidence in a few weeks.

On the 8th of April 1746 he set out from Aberdeen towards Inverness, and on the 15th he fought the decisive battle of Culloden, in which, and in the pursuit which followed, the forces of the Pretender were completely destroyed. He had become convinced that the sternest measures were needed to break down the Jacobitism of the Highlanders. He told his troops to take notice that the enemy's orders were to give no quarter to the "troops of the elector," and they took the hint. No trace of such orders remains (see Murray, Lord George), and it is probable that Cumberland had merely received word of wild talk in the enemy's camp, which he credited the more easily as he thought that those who were capable of rebellion were capable of any crime. On account of the merciless severity with which the fugitives were treated, Cumberland received the nickname of the "Butcher." That the implied taunt was unjust need not be laboured. It was used for political purposes in England, and his own brother, the prince of Wales, encouraged, it appears, the virulent attacks which were made upon the duke. In any case there is a marked similarity between Cumberland's campaign and that in Scotland and that of Cromwell in Ireland. Both dared to do acts which they knew would be cast against them for the rest of their lives, and terrorized an obstinate and unyielding enemy into submission. How real was the danger of a protracted guerrilla warfare in the Highlands may be judged from the explicit declarations of Jacobite leaders that they intended to continue the struggle. As it was, the war came to an end almost at once. Here, as always, Cumberland preserved the strictest discipline in his camp. He was inflexible in the execution of what he deemed to be his duty, without favour to any man. At the same time he exercised his influence in favour of clemency in special cases that were brought to his notice. Some years later James Wolfe spoke of the duke as "for ever doing noble and generous actions."

The relief occasioned to Britain by the duke's victorious efforts was acknowledged by his being voted an income of £40,000 per annum in addition to his revenue as a prince of the royal house. The duke took no part in the Flanders campaign of 1746, but in 1747 he again opposed the still victorious Marshal Saxe; and received a heavy defeat at the battle of Lauffeld, or Val, near Maastricht (2nd of July 1747). During the ten years of peace Cumberland occupied himself chiefly with his duties as captain-general, and the result of his work was clearly shown in the conduct of the army in the Seven Years' War. His unpopularity, which had steadily increased since Culloden, interfered greatly with his success in politics, and when the death of the prince of Wales brought a minor next in succession to the throne the duke was not able to secure for himself the contingent regency, which was vested in the princess-dowager of Wales. In 1757, the Seven Years' War having broken out, Cumberland was placed at the head of a motley army of ill-disciplined Hanover. At Hastenbeck, near Hameln, on the 26th of July 1757, he was defeated by the superior forces of D'Estrees (see Seven Years' War). In September of the same year his defeat had almost become disgrace. Driven from point to point, and at last hemmed in by the French under Richelieu, he capitulated at Klosterzeven on the 8th of the month, agreeing to disband his army and to evacuate Hanover. His disgrace was completed on his return to England by the king's refusal to be bound by the terms of the duke's agreement. In chagrin and disappointment he retired into private life, after having formally resigned the public offices he held. In his retirement he made no attempt to justify his conduct, applying in his own case the discipline he had enforced on others. For a few years he lived quietly at Windsor, and subsequently in London, taking but little part in politics. He did much, however, to displace the Bute ministry and that of Grenville, and endeavoured to restore Pitt to office. Public opinion had now set in his favour, and he became almost as popular as he had been in his youth. Shortly before his death the duke was requested to open negotiations with Pitt for a return to power. This was, however, unsuccessful. On the 31st of October 1795 the duke died.

A Life of the duke of Cumberland by Andrew Henderson was published in 1796, and an edition in 1876, (Richard Rolle) Historical Memoirs appeared in 1767. See especially A. N. Campbell Maclachlan, William Augustus, Duke of Cumberland (1876).

CUMBERLAND, the north-westernmost county of England, bounded N. by the Scottish counties of Dumfries and Roxburgh, E. by Northumberland, S. by Westmorland and Lancashire, and W. by the Irish Sea. Its area is 1520-4 sq. m. In the south the county includes about one-half of the celebrated Lake District (q.v.), with the highest mountain in England, Scafell Pike (3210 ft.), and the majority of the principal lakes, among which are Derwentwater and Bassenthwaite, Buttermere and Crummock Water, Ennerdale, Waswater, and, on the boundary with Westmorland, Ullswater. From this district valleys radiate north, west and south to a flat coastal belt, the widest part of which (about 8 m.) is found in the north in the Solway Plain, bordering Solway Firth, which here intervenes between England and Scotland. The valley of the Eden, opening upon this plain from the south-east, separates the mountainous Lake District from the straight, westward face of a portion of the Pennine Chain (q.v.), which, with the Solway Firth, in this county, reaches its highest point within it in Cross Fell (2930 ft.). A well-marked pass, called the Tyne Gap, at the water-parting between the rivers Irthing and South Tyne, traversed by the Newcastle & Carlisle railway, intervenes between these hills and their northerward continuation in the hills of the Scottish border. Besides the waters of the Eden, Solway Firth receives those of the Esk, which enter Cumberland from Scotland. Liddel Water, joining this river from the north east, from Liddisdale, forms a large part of the boundary with Scotland. The Eden receives the Irthing from the east, and from the Lake District the Calder, rising beneath Skiddaw and joining the main river at Carlisle, and the Eamont, draining Ullswater and forming part of the boundary with Westmorland. The principal streams flowing east and south from the Lake District are the Derwent, from Borrowdale and Derwentwater, the Eden from Ennerdale, the Esk from Eskdale, and the Duddon, forming the greater part of the boundary with Lancashire. There are valuable salmon fisheries in the Eden, and trout are taken in many of the streams and lakes.

Geology.—The mountainous portion of Cumberland is built up of two different types of rock. The older, a sedimentary slaty series of Ordovician age, the Skiddaw slates, surrounds Bassenthwaite, Saddleback, Crummock Water, Keswick and Cockermouth and the western end of Ennerdale Water. The same formation is found in the northern flanks of Ullswater also north and east of Whitebeck. The other type of rock is volcanic; it gives a more rugged aspect to the scenery, as may be seen in comparing the rough outlines of Scafell and Helvellyn with the smoother form of Saddleback or Skiddaw. These volcanic rocks, owing to much
alteration, are often slaty; they have been called the "green slates and porphyries" or the Borrowdale Series. The Skiddaw slates are usually separated from the newer green slates above them by a plane of differential movement, for both have been thrust by earth-pressure from south to north, but the former rocks have travelled further than the latter which have lagged behind; hence Messrs Marr and Barker describe the plane of separation as a "lag-fault." Much general faulting and folding have resulted from the movement; the thrusting took place in Devonian times. About the same period, granitic rock was intruded into the slates in the form of laccolites, which often lie along the lap lages. Such rocks are the granophyre hills of Buttermere and Ennerdale, the granite patches on either side of the Vale of St John, and the great mass of diabase which separates the Warsash and Black Combe blocks of Black Combe. At Carrock Fell, N.E. of Skiddaw, is an extremely interesting complex of volcanic rocks, and in many other places are diabase and other forms, e.g. the well-known rock at Castle Head, Keswick.

From Pooley Bridge, Ullswater, on the east, by Udale round to Egremont on the west, the mountainous region just described, is surrounded by the Carboniferous Limestone series, with a conglomeration at the base. Upon these rocks the coalfield of Whiteside rests and extends as far as Maryport. The coal seams are worked for some distance beneath the sea. The vale of Eden between Penrith, Hornby and Wray is occupied by Permian sandstone. Usually bright red in colour, red Triassic rocks form a strip about 4 m. wide, the Permian outcrop; a similar strip forms a coastal fringe from St Bees Head to Duddon Sands. The same formations are spread out round Carlisle, Brampton, Longtown, Wigton and Aspatria. East of Carlisle they are covered by an outwash of the Solway sands. The Eskdale Slates form a broad series on the eastern side of the vale of Eden; it throws up the Lower Carboniferous limestones with their associated shales and sandstones to form the elevated ground in the north and north-east of the county. Several basic intrusive rocks are the limestone series, the best known being the Whin Sill, which may be traced for a number of miles northward from Criffell. Evidences of glacial action are abundant; till with sands and gravel lie on the lower ground; striated rocks and rocks famous are common; peridot blocks are found on the plateau by Sprinkling Tarn and elsewhere. Moraine mounds are quite numerous in the valleys, and have frequently been the cause of small lakes.

Climate and Agriculture.—The climate is generally temperate, but in the higher parts bleak, snow sometimes lying fully six months of the year on Cross Fell and the mountains of the Lake District. As regards rainfall, the physical configuration makes for contrast. At Carlisle, on the Solway plain, the mean annual fall is 30.6 in. At Penrith, on the north-eastern flank of the Lake District, it is 37.67 in.; on the western flank, 41.33 in.; at Ravenglass, close to the coast, and 41.78 in. Cockermouth, some miles inland. In the heart of the district, however, the fall is as a rule much heavier, in fact, the heaviest recorded in the British Isles (see Lake District). Somewhat less than three-fifths of the total area of the county is under cultivation, the proportion being higher than that of the neighbouring counties of Northumberland and Westmorland, but still much below the average of the English counties. Black peaty earth is the most prevalent soil in the mountainous districts; but dry loams occur in the lowlands, and are well adapted to green crops, grain and pasture. Wheat and barley are practically neglected, but large crops of oats are grown. Turnips and swedes form the bulk of the green crops. Hill pasture amounts to nearly 270,000 acres, and a good number of cattle are reared, but the principal resource of the farmer is sheep-breeding. The sheep on the lowland farms are generally of the Leicester class or cross-bred between the Leicester and Herdwick, with a few Southdowns. Throughout the mountainous districts the Herdicks have taken the place of the smaller black-faced heath variety of sheep once bred there; they are peculiar to this part of England; the ewes and wethers and many of the rams are polled, the faces and legs are speckled, and the wool is finer and heavier in fleece than that of the heath breed. They originally came from the neighbourhood of Muncaster in the Duddon and Esk district, and tradition ascribes their origin variously to introduction by Scandinavian settlers, or to parents that escaped from a wrecked ship of the Spanish Armada. In general they belong to the proprietors of the sheep-walks, and have been farmed out with them from time immemorial, from which circumstance it is said they obtained the name of "Herdwicks." Long after the Norman Conquest Cumberland remained one of the most densely forested regions of England, and much of the low-lying land is still well wooded, the Lake District in particular displaying beautiful contrasts between bare mountain and tree-clad valley. The oak, ash and birch are the principal natural trees, while yew, thorn and juniper flourish locally.

Land and property was formerly much divided in this county, and the smaller holdings were generally occupied by their owners, who were known as "statesmen," i.e. "estatesmen," a class of men long noted for their sturdy independence and attachment to routine husbandry. Most of these estates were held of the lords of manors under customary tenure, which subjected them to the payments of fines and heriots on alienation as well as on the death of the lord or tenant. According to the Agricultural Survey printed in 1794, about two-thirds of the county was held by this tenure, in parcels worth from £15 to £30 rental. On large estates, also, the farms were in general rather small, few then reaching £200 a year, held on verbal contracts, or very short leases, and burdened like the small estates with payments or services over and above a money rent. In modern times these constraints, the "chain" of holdings, are gradually becoming extinct as a class, and most of the small holdings falling into the hands of the larger landed proprietors.

Other Industries.—Carlisle is the seat of a variety of manufactures; there are also in the county cotton and woollen industries, pencil mills at Keswick, and iron shipbuilding yards at Whitehaven. But the mining industry is the most important, coal being raised principally in the district about Whitehaven, Workington and Maryport. Side by side with this industry much iron ore is raised, and there is a large output of pig-iron, and ore is also found in the south, in the neighbourhood of Millom. Gypsum, zinc and some lead are mined. Copper was formerly worked near Keswick, and there was a rich deposit of black lead at the head of Borrowdale. Granite and limestone are extensively quarried. Stone is very largely used even for housebuilding, a fine green slate being often employed. Shap and other granites are worked for building and roadstones.

Communications.—The chief ports of Cumberland are Whitehaven, Workington, Maryport, Harrington and Silloth. The London and North-Western railway enters the county near Penrith, and terminates near Carlisle, by the Midland. The Caledonian, North British and Glasgow & South-Western lines further serve this city, which is thus an important junction in through communications between England and Scotland. The North-Eastern railway connects Carlisle with Newcastle. The Maryport & Carlisle, the Cockermouth, Keswick & Penrith, and the Cleator & Workington Junction lines serve the districts indicated by their names, while the Furness railway passes along the west coast from the district of Furness in Lancashire as far north as Whitehaven, also serving Cleator and Egremont. The Ravenglass & Eskdale light railway gives access from this system to Boot in Eskdale. Coaches and motor cars maintain passenger communications in the Lake District where the railways do not penetrate.

Population and Administration.—The area of the ancient and the administrative county is 973,866 acres, with a population in 1891 of 266,049 and in 1901 of 266,933. The county contains five wards, divisions which in this and neighbouring counties correspond to hundreds, and also appear in Lanarkshire and Renfrewshire. The county is divided into 27 civil parishes, with the exception of the townships of Carlisle (pop. 45,480), a city and the counties of Whitehaven (19,324) and Workington (26,143). The other urban districts are Arlecdon and Frizington (5341), Aspatria (2885), Cleator Moor (8120), Cockermouth (5355), Egremont (5791), Harrington (5679), Holme Cultram (2472), Keswick (4451), Maryport (11,897), Millom (10,426), Penrith (9872), Wigton (3692). Of these except Keswick, Millom and Penrith are in the industrial district of the west and north-west. The urban district of Holme Cultram includes the port of Silloth. Among lesser towns may be mentioned St Bees (1236), on the coast south of Whitehaven,
until 1897 the seat of a Church of England theological college. The grammar school here, founded in 1533, is liberally endowed, with scholarships and exhibitions. Cumberland is in the northern circuit, and asizes are held at Carlisle. It has one court of quarter sessions and 12 petty sessional divisions. The city of Carlisle has a separate commission of the peace and court of quarter sessions. There are 213 civil parishes. Cumberland is in the diocese of Carlisle, with a small portion in that of Newcastle. There are 167 ecclesiastical parishes or districts within the county. There are four parliamentary divisions, the Northern or Eskdale, Mid or Penrith, Cockermouth and Western or Egremont, each returning one member; while the parliamentary boroughs of Carlisle and Whitehaven each return one member.

History.—After the withdrawal of the Romans (of whose occupation there are various important relics in the county) little is known of the region which is now Cumberland, until the great battle of Arderyd in 573 resulted in its consolidation with the kingdom of Strathclyde. About 670-680 the western district between the Solway and the Merey was conquered by the Angles of Northumbria and remained an integral portion of that kingdom until the Danish invasion of the 9th century. In 875 the kingdom of the Cumbri is referred to, but without any indication of its extent, and the first mention of Cumberland to denote a geographical area occurs in 945 when it was ceded by Edmund to Malcolm of Scotland. At this date it included the territory north and south of the Solway from the Firth of Forth to the river Duddon. The Scottish supremacy was not uninterrupted, for the district at the time of its invasion by Ethelred in 1000 was once more a stronghold of the Danes, whose influence is clearly traceable in the nomenclature of the Lake District. At the time of the Norman invasion Cumberland was a dependency of the earldom of Northumbria, but its history at this period is very obscure, and no notice of it occurs in the Domesday Survey of 1086; Kirkcanton, Bootle and Whicham, however, are entered under the possessions of the earl of Northumbria in the West Riding of Yorkshire. The real Norman conquest of Cumberland took place in 1092, when William Rufus captured Carlisle, repaired the city, built the castle, and after sending a number of English husbandmen to till the land, placed the district under the lordship of Ranulf Mescines. The see of Ranulf was called the Power or Honour of Carlisle, and a sheriff of Carlisle is mentioned in 1166. The district was again captured by the Scots in the reign of Stephen, and on its recovery in 1137 the boundaries were readjusted to include the great barony of Copland. At this date the district was described as the county of Carlisle, and the designation county of Cumberland is not adopted in the sheriff's accounts until 1177. The five present wards existed as administrative areas in 1278, when they were termed bailiwicks, the designation ward not appearing until the 16th century, though the bailiwicks of the Forest of Copland and the Vale of Eden were in the 14th century. In the 17th and 18th centuries each of the five wards was under the administration of a chief constable.

Owing to its position on the Border Cumberland was the scene of constant warfare from the time of its foundation until the union of England and Scotland, and families like the Tilliols, the Luics, the Greystokes, and the Dacres were famous for their exploits in checking or avenging the depredations of the Scots. During the War of Independence in the reign of Edward I. Carlisle was the headquarters of the English army. In the Wars of the Roses the prevailing sympathy was with the Lancastrian cause, which was actively supported by the representatives of the families of Egremont, Dacre and Greystoke. In 1452 the Scottish army under James V. suffered a disastrous defeat at Solway Moss. After the union of the crowns of England and Scotland in 1603, the countries hitherto known as 'the Borders' were called 'the Middle Shires,' and a period of comparative peace ensued. On the outbreak of the Civil War of the 17th century the northern counties associated in raising forces for the king, and the families of Howard, Dalston, Dacre and Musgrave rendered valuable service to the royalist cause. In 1645 Carlisle was captured by the parliamentary forces, but in April 1648 it was retaken by Sir Philip Musgrave and Sir Thomas Glenham, and did not finally surrender until the autumn of 1648. Cumberland continued, however, to support the Stuarts; it was one of the first counties to welcome back Charles II.; in 1715 it was associated with the rising on behalf of the Pretender, and Carlisle was the chief seat of operations in the 1745 rebellion.

In 685 Carlisle and the surrounding district was annexed by Egfrith king of Northumbria to the diocese of Lindisfarne, to which it continued subject, at least until the Danish invasion of the 9th century. In 1135 Henry I. created Carlisle (q.v.) a bishopric. The diocese included the whole of modern Cumberland (except the barony of Coupland and the parishes of Alston, Over-Denton and Kirkandrews), and also the barony of Appleby in Westmorland. The archdeaconry of Carlisle, co-extensive with the diocese, comprised four deaneries. Carlisle was a deanship in the archdeaconry of Richmond and diocese of York until 1541, when it was annexed to the newly created diocese of Chester. In 1546 the area of the deanship of Carlisle was extended, so as to include the whole of Cumberland except the parish of Alston, the whole of Westmorland, and the Furness district of Lancashire. In 1585 the deaneries were made to number eighteen, and in 1670 were increased to twenty.

The principal industries of Cumberland have been from earliest times connected with its valuable fisheries and abundant mineral wealth. The mines of Alston and the iron mines about Egremont were worked in the 12th century. The Keswick copper mines were worked in the reign of Henry III., but the black-lead mine was not worked to any purpose until the 18th century. Coal mining is referred to in the 15th century, and after the revival of the mining industries in the 16th century, rose to great importance. The salt pans about the estuaries of the Esk and the Eden were a source of revenue in the 12th century.

Cumberland returned three members for the parliament of 1290, and in 1295 returned in addition two members for the city of Carlisle and two members each for the boroughs of Cockermouth and Egremont. The boroughs did not again return members until in 1640 Cockermouth regained representation. Under the Reform Act of 1832, Cumberland returned four members for two divisions, and Whitehaven returned one member. The county now returns six members to parliament; one each for the four divisions of the county, Egremont, Cockermouth, Eskdale and Penrith, one for the city of Carlisle and one for the borough of Whitehaven.

Antiquities.—Very early crosses, having Celtic or Scandinavian characteristics, are seen at Gosforth, Bewcastle and elsewhere. In ecclesiastical architecture Cumberland is not rich as a whole, but it possesses Carlisle cathedral, with its beautiful choir, and certain monastic remains of importance. Among these are the fine remains of Lanercost priory (see Brampton). Calder Abbey, near Egremont, a Cistercian abbey founded in 1134, has in the church and cloisters a fine example of the English character, and is very beautifully situated on the Calder. The parish Church of St Bees, with good Norman and Early English work, belonged to a Benedictine priory of 1120; but according to tradition the first religious house here was a nunery founded c. 650 by St Bega, who became its abbess. Among the parish churches there are a few instances of towers strongly fortified for purposes of defence; that at Burgh-on-the-Sands, near Carlisle, being a good illustration. Castles, in some cases ruined, in others modernized, are fairly numerous, both near the Scottish border and elsewhere. Naworth Castle near Brampton is the finest example; others are at Bewcastle, Carlisle, Kirkcudworth, Egremont, Cockermouth and Milom. Among many notable country seats, Rose Castle, the palace of the bishops of Carlisle; Greystoke Castle and Armstrong Hall may be mentioned.

CUMBERLAND—CUMBERLAND RIVER

Society. 1875, with a supplement, 1881; Sir G. F. Duckett, Early
Sheriffs of Cumberland (Kendal, 1879); J. Denton, "Account of
Estates and Families in the County of Cumberland, 1666–1693," in
Antiquarian Society's Transactions (1887); R. S. Ferguson, History of
Cumberland (London, 1890); "Archaeological Survey of Cumber-
land," in Archaeologia, vol. liii. (London, 1893); W. Jackson, Popu-
lations and Pedigrees relating to Cumberland (2 vols., London, 1892); T.
Elwood, The Landscape Book of Iceland as it Illustrates the Dialect
and Antiquities of Cumberland (Kendal, 1894); Victoria County
History, Cumberland; and Transactions of the Cumberland and
Westmorland Antiquarian and Archaeological Society.

CUMBERLAND, a city and the county-seat of Allegany
county, Maryland, U.S.A., on the Potomac river, about 175 m.
W. by N. of Baltimore and about 153 m. S. by E. of Pittsburgh.
Pop. (1800) 12,729; (1900) 17,126, of whom 1113 were foreign-
born and 1100 were of negro descent; (1910) 21,839.
Cumberland is served by the Baltimore & Ohio, the Western
Maryland, the Pennsylvania, the Cumberland & Pennsylvania
(from Cumberland to Piedmont, Virginia), and the George's
Creek & Cumberland railways, the last a short line extending
to Lonacoming (10 m.); by an electric line extending to Western
Port, Maryland; and by the Chesapeake & Ohio Canal, of which
it is a terminus. The city is about 635 ft. above sea-level, and
from a distance appears to be completely shut in by lofty ranges
of hills, which are cut through to the westward by a deep gorge
called "The Narrows," making a natural gateway of great
beauty. Cumberland has a large trade in coal, which is mined
in the vicinity. As a manufacturing centre it ranked in 1905 second
in the state, the chief products being iron, steel, bricks, flour,
cement, silk and leather; there is also a large dyeing and clean-
ing establishment. The value of the city's factory products
increased from $2,906,267 in 1900 to $3,495,023 in 1905, or
58.4%. Cumberland is an important joinging centre also. The
municipality owns and operates its water-works and electric
lighting plant. The first settlement of the place was made in
1750; in 1754 Fort Cumberland was erected within what are
now the city limits, and in the year following this fort was
occupied by General Edward Braddock. Cumberland was laid
out in 1753, but there was little growth until 1787, and it was not
incorporated as a town until 1815; it was chartered as a city in
1830.

CUMBERLAND, a township of Providence county, Rhode
Island, U.S.A., in the N.E. part of the state, about 6 m. N.
of Providence and having the Blackstone river for most of its
W. boundary. Pop. (1800) 8090; (1900) 8255, of whom 3473
were foreign-born; (1910) 10,107; area, 27-5 sq. m.
It is served by the New York, New Haven & Hartford railway.
Within its borders are the villages of Cumberland Hill, Diamond
Hill, and Millington. Abbott Run, Bellingham, Robin Hollow, Happy
Hollow, East Cumberland, and part of the town of Millville,
Lonsdale and Valley Falls. The surface of the township is generally
hilly and rocky. In the N. part there is a valuable granite quarry;
and limestone, and some coal, iron and gold are also found.
Cumberland has been called the "mineral pocket of New
England." The Blackstone and its tributaries provide considerable
water power; and there are various manufactures, including
cotton goods, silk goods, and horse-shoes and other iron ware.
The value of the township's factory product in 1905 was
$3,171,318, an increase of 80.6% since 1900, this ratio of increase
being greater than that shown by any other "municipality"
in the state having a population in 1900 of 8000 or more. At
Lonsdale, William Blackstone (c.1695–1765), the first permanent
white settler within the present limits of Rhode Island, built
his residence, "Study Hall," about 1635. Cumberland was
originally a part of the Province of Massachusetts Bay, and for
many years was called, like other sparse settlements,
the Gores, or Attleborough Gore. In 1747, by the royal
decree establishing the boundary between Massachusetts and
Rhode Island, Attleborough Gore, with other territory formerly
under the jurisdiction of Massachusetts, was annexed to Rhode
Island, and the township of Cumberland was incorporated,
the name being adopted in honour of William Augustus, duke of
Cumberland. In 1867 a part of Cumberland was set off to form
the township of Woonsocket.

CUMBERLAND MOUNTAINS (or more correctly the Cumber-
land Plateau or Highlands), the westernmost of the three great
divisions of the Appalachian uplift in the United States, com-
posed of many small ranges of mountains (of which Cumberland
Mountain in eastern Kentucky is one). It extends from Pennsyl-
mania to Alabama, attaining its greatest height (about 4000 ft.)
in Virginia. The plateau is rich in a variety of mineral products,
of which special mention may be made of coal, which occurs
in many places, and of the beautiful marbles quarried in that
portion of the plateau which lies between Virginia and Kentucky
and crosses Tennessee. The plateau has an abrupt descent,
almost an escarpment, into the great Appalachian Valley on its
E., while the W. slope is deeply and roughly broken. The whole
mass is eroded in Virginia into a maze of ridges. Cumberland
Mountain parts the waters of the Cumberland and Tennessee
rivers. This range and the other ranges about it are perhaps the
loveliest portion of the whole plateau. The peaks here and in the
Blue Ridge to the E. are the highest of the Appalachian system.
Forest-filled valleys, rounded hills and rugged gorges afford
in every part scenery of surpassing beauty. The Cumberland Valley
between the Cumberland range and the Pine range is one of
special fame. In the former range there are immense caverns
and subterranean streams. Cumberland Gap, crossing the ridge
at about 167 ft. above the sea, where Kentucky, Virginia and
Tennessee meet, is a gorge about 300 ft. deep, with steep sides
that barely give room in places for a roadway. The mountains,
river and gap were discovered by a party of Virginians in
1748, and named in honour of the victor of Culloden, William,
duke of Cumberland. Afterwards the gap gained a place in
American history as one of the main pathways by which
emigrants crossed the mountains to Kentucky and Tennessee.
During the Civil War it was a position of great strategic
importance, as it afforded an entrance to eastern and central
Tennessee from Kentucky, which was held by the Union army;
and it was repeatedly occupied in alternation by the opposing
forces.

The mountaineers of Kentucky and Tennessee are a strange
stock, who retain in their customs and habits the primitive
conditions of a life that has elsewhere long since disappeared.
They have been pictured in the novels of Miss Murfree and John
Fox, Junr. They are a tall, straight, angular folk, of fine physical
development; the volunteers for the Union army from Kentucky
and Tennessee during the Civil War—most of whom came from
the non-slave-holding mountain region—exceeded in physical
development the volunteers from other states. For the education
of these mountaineers Major-General Oliver Otis
Howard founded in 1865 at Cumberland Gap, Tennessee, the
Lincoln Memorial University (co-educational; non-sectarian;
opened in 1867), which has collegiate, normal training and indus-
trial courses, and an affiliated school of medicine, Tennessee
Medical College, at Knoxville. The university had in 1907–1908
14 instructors and 570 students. Berea College in Kentucky was
a pioneer institution for the education of mountaineers.

CUMBERLAND RIVER, a large southern branch of the Ohio
river, U.S.A., rising in the highest part of the Cumberland plateau
in south-east Kentucky, and emptying into the Ohio in Kentucky
(near Smithland) after a devious course of 688 m. through that
state and Tennessee. It drains a basin of somewhat more than
18,000 sq. m., and is navigable for light-draft steamers through
about 500 m. under favourable conditions—Burnside, Pulaski
county, 318 m. from the mouth, is the head of navigation—and
through 193 m.—to Nashville—all the year round; for boats
drawing not more than 3 ft. the river is navigable to Nashville for
about 700 m. Above Great Falls, in Whitley county, Kentucky,
it drops precipitously 6 ft.; above the falls it is a mountain
stream, of little volume in the dry months. It descends rapidly
at its head to the highland bend below the mountains and
traverses this to the falls, then flows in rapids (the Great Shoals)
for some 10 m. through a fine gorge with cliffs 300–400 ft. high,
and descends between bluffs of decreasing height and beauty
into its lower level. Save in the mountains its gradient is slight,
and below the falls, except for a number of small rapids, the
flow of the stream is equable. Timbered ravines lend charm to much of its shores, and in the mountains the scenery is most beautiful. Below Nashville the stream is some 400 to 500 ft. wide, and its high banks are for the most part alluvium, with rocky bluffs at intervals. At the mouth of the river lies Cumberland Island, in the Ohio. During low water of the latter stream the Cumberland discharges around both ends of the island, but in high water of the Ohio the gradient of the Cumberland is so slight that its waters are held back, forming a deep quiet pool that extends some 20 m. up the river. A system of locks and dams below Nashville was planned in 1846 by a private company, which accomplished practically nothing. Congress appropriated $155,000 in 1832–1838; in the years immediately after 1888 $305,000 was expended, notably for deepening the shoals at the junction of the Cumberland and the Ohio; in 1892 a project was undertaken for 7 locks and dams 52 ft. wide and 280 ft. long below Nashville. Above Nashville $346,000 was expended on the open channel project (of 1871–1872) from Nashville to Cumberland Ford (at Pineville); in 1886 a canalization project was undertaken for 22 locks and dams below Burnside and 6 above Burnside were planned, but by the act of 1907 the project was modified—$2,319,000 had been appropriated up to 1908 for the work of canalization. During the Civil War Fort Donelson on the Cumberland, and Fort Henry near by, were occupied by the Confederates, and their capture by Flagofficer A. H. Foote and General Grant (Feb. 1862) was one of the decisive events of the war, opening the rivers as it did for the advance of the Union forces far into Confederate Territory.

**CUMBRAES, THE—CUMMING**

The two islands forming part of the county of Bute, Scotland, lying in the Firth of Clyde, between the southern shores of Bute and the coast of Ayrshire. Great Cumbrae Island, about 1 1/2 m. W.S.W. of Largs, is 3 1/2 m. long and 2 m. broad, and has a circumference of 10 m. and an area of 3200 acres or 5 sq. m. Its highest point is 417 ft. above the sea. There is some fishing and a little farming, but the mainstay of the inhabitants is the custom of the visitors who crowd every summer to Millport, which is reached by railway steamer from Largs. This town (pop. 1901, 1663) is well situated at the head of a fine bay and has a climate that is both warm and bracing. Its chief public buildings include the cathedral, erected in Gothic style on rising ground behind the town, the college connected with it, the garrison, a picturesque seat belonging to the marquess of Bute, who owns the island, the town hall, a public hall, library and reading room, the Lady Margaret female hospital, and the military barracks. Originally the collegiate church, was founded in 1849 by the earl of Glasgow and opened in 1852. In 1876 it was constituted the cathedral of Argyll and the Isles. Millport enjoys exceptional facilities for boating and bathing, and there is also a good golf-course. Pop. (1901) 1754, of whom 1028 were females, and 59 spoke both English and Gaelic. Little Cumbrae Island lies to the south, separated by the Tan, a strait half a mile wide. It is 1 1/2 m. long, barely 1 m. broad, and has an area of almost a square mile. Its highest point is 409 ft. above sea-level. On the bold cliffs of the west coast stands a lighthouse. Robert II. is said to have built a castle on the island which was demolished by Cromwell's soldiers in 1653.

The strata met with in the Great and Little Cumbrae belong to the Upper Old Red Sandstone and Carboniferous systems. The former, consisting of false-beded sandstones and conglomerates, are confined to the larger island. The Carboniferous rocks of the Cumbraes belong to the lower part of the Calciferous Sandstone series with the accompanying volcanic zone. In the larger island these sediments, consisting of fine sandstone, coal, and pebbly siltstone, are underlain by bands of nodular limestone or carbonite, occupy a considerable area on the north side of Millport Bay. In the Little Cumbrae they appear on the east side, where they underlie and are interbedded with the lavas and dikes, forming the feature known as the geological feature of Lower Carboniferous volcanic rocks. They cover nearly the whole of the Little Cumbrae, where they give rise to marked terraced features and are arranged in a gentle synclinal fold. The flows are often scarceaceous at the top and sometimes display columnar structure, as in the crags at the lighthouse. These rocks examined microscopically consist of basalts which are often porphyritic.

In Great Cumbrae the intrusive rocks mark four periods of eruption, three of which may be of Carboniferous age. The oldest, consisting of trachyte, occur as sheets and dikes trending generally E.N.E., and are confined chiefly to the Upper Old Red Sandstone. They seem to be of older date than the Carboniferous lavas of Little Cumbrae and south Bute. Next come dikes of olivine basalt of the type of the Lion's Haunch on Arthur's Seat, which, though possessing the same general trend as the trachytes, are seen to cut them. The members of the third group comprise dikes of dolerite or basalt with or without olivine, which have a general east and west trend, and as they intersect the two previous groups they must be of later date. They probably belong to the east and west quartz dolerite dikes which are now referred to late Carboniferous time. Last, there are representatives of the basalt dikes of Tertiary age with a north-west trend.

**CUMIN, or CUMMIN (Cuminum Cyminum),** an annual herbaceous plant, a member of the natural order Umbelliferae and probably a native of some part of western Asia, but scarcely known at the present time in a wild state. It was early cultivated in Arabia, India and China, and in the countries bordering the Mediterranean. Its stem is slender and branching, and about a foot in height; the leaves are deeply cut, with filiform segments; the flowers are small and white. The fruits, the so-called seeds, which consist of the collection of pistil and ovary, are oval in shape and compressed laterally; they are two lines long, more to the taste, lighter in colour, and larger than caraway seeds, and have on each half nine fine ridges, overlying as many oil-channels or vittae. Their strong aromatic smell and warm bitterish taste are due to the presence of about 3% of an essential oil. The tissue of the seeds contains a fatty oil, with resin, mucilage and gum, malates and alluminous matter; and in the pericarp there is much tannin. The volatile oil of cumin, which may be separated by distillation of the seed with water, is mainly a mixture of cymol or cymene, C6H4, and cumin aldehyde, C6H4(C2H5)OH. Cumin is mentioned in Isaiah xxviii. 25, 27, and Matthew xxiii. 23, and in the works of Hippocrates and Dioscorides. From Pliny we learn that the ancients took the ground seed medicinally with bread, water or wine, and that it was accounted the best of condiments as a remedy for squeamishness. It was found to occasion pallor of the face, whence the expression of Horace, exsangue cuminum (Epist. i. 10), and that of Persius, palentis grana cumini (Sat. v. 55). Pliny relates the story that it was employed by the followers of Porcius Latro, the shipwrecked Greek, in their shipwreck to maintain life. The complex mixture of cumin, such as bespeaks application to study (xx. 57). In the middle ages cumin was one of the commonest spices of European growth. Its average price per pound in England in the 13th and 14th centuries was 2d. or at present value, about 1s. 4d. (Rogers, Hist. of Agric. and Prices, i. 631). It is stimulant and carminative, and is employed in the manufacture of curdy powder. The medicinal use of the drug is now confined to veterinary practice. Cumin is exported from India, Mogador, Malta and Sicily.

**CUMMERTON, a green or waistbelt (Hindostani kamar-band, a loin-band). In the East the principle of health is to keep the head cool and the stomach warm; the turban protects the one from the sun, and the cummerton ensures the other against changes of temperature. In India the cummerton consists of many folds of muslin or bright-coloured cloth.

**CUMMING, JOSEPH GEORGE (1812–1868), English geologist and archaeologist, was born at Matlock in Derbyshire on the 15th of February 1812. He was educated at Oakham grammar school, and Emmanuel College, Cambridge, taking the degree of B.A., and entering holy orders in 1835. In 1841 he was appointed vicar of King William's College, Castletown, in the Isle of Man, and held the position in which he remained during this period his leisure time was devoted to a study of the prehistoric and archaeology of the island. The results were published in a classic volume The Isle of Man; its History, Physical, Ecclesiastical, Civil and Legendary (1848). In 1856 he became master of King Edward's grammar school at Lichfield, in 1858 warden and professor of classical literature and geology in Queen's College, Birmingham, in 1862 rector of Meliss, in Suffolk, and in 1867 vicar of St John's, Bethnal Green, London. He died in London on the 21st of September 1868.**
CUMNOCK AND HOLMEHEAD, a police burgh of Ayrshire, Scotland, on the Lugar, 33.5 m. S. of Glasgow by road, with two stations (Cumnock and Old Cumnock) on the Glasgow & South-Western railway. Pop. (1901) 3088. It lies in the parish of Old Cumnock (pop. 5144), and is a thriving town, with a town hall, cottage hospital, public library and an almonry. Coal and ironstone are extensively mined in the neighbourhood, and the manufactures include woollens, tweeds, agricultural implements and pottery. When Alexander Peden (1626-1680), the persecuted Covenanter, died, he was buried in the Boswell aisle of Auchinleck church; but his corpse was borne thence with every indignity by a company of dragoons to the foot of the gallows at Cumnock, where they intended to hang it in chains. This proving to be impracticable they buried it at the gallows-foot. After the Revolution the inhabitants out of respect for the "Prophet's" memory abandoned their then burying-ground and turned the old place of execution into the present cemetery. Five miles S.E. lies the parish of New Cumnock (pop. 3597) at the confluence of Afton Water and the Nith. It is rich in minerals, iron, coal, limestone and freestone, and has a station on the Glasgow & South-Western railway. Two miles N.W. of Cumnock is Auchinleck (pronounced Affleck), with a station on the Glasgow & South-Western railway. Coal and iron mining and farming are important industries. It is the seat of the Boswell family, three generations of which achieved greatness—Lord Auchinleck, the judge (who dubbed Dr Johnson "Urs Major"!), his son James, the biographer, and his grandson Sir Alexander, the author of "Gude nicht and Joy be wi' you a'"!, "Jenny's Bawbee," "Jenny dang the weaver," and other songs and poems, which perished miserably in a duel. Pop. of Auchinleck parish (1901) 6605.

CUNARD, SIR SAMUEL, Bart. (1787-1865), British civil engineer, founder of the Cunard line of steam-ships, was born at Halifax, Nova Scotia, on the 21st of November 1787. He was the son of a merchant, and was himself trained for the pursuits of commerce, in which, by his abilities and enterprising spirit, he attained a conspicuous position. When, in the early years of steam navigation, the English government made known its desire to substitute steam vessels for the sailing ships then employed in the mail service between England and America, Cunard heartily entered into the scheme, came to England, and accepted the government tender for carrying it out. In conjunction with Messrs Burns of Glasgow and Messrs Maciver of Liverpool, proprietors of rival lines of coasting steamers between Glasgow and Liverpool, he formed a company, and the first voyage of a Cunard steamship was successfully made by the "Britannia" from Liverpool to Boston, U.S.A., between July 4 and 16, 1840 (see STEAMSHIP LINES). In acknowledgment of his energetic and successful services Cunard was, in 1859, created a baronet. He died in London on the 28th of April 1865.

CUNAS, a tribe of Central American Indians. Their home is the Isthmus of Panama, from the Chucoves to the Atroto. They are sometimes called Darién or San Blas Indians. They are a small active people, with remarkably light complexions.

CUNDINAMARCA, till 1909 a department of the eastern plateau of Colombia, South America, having the departments of Quesada and Tundama on the N., Tolima on the W. and S., and the Meta territory on the S.E. and E. The territorial redistribution of 1905 deprived Cundinamarca of its territories on the eastern plains, and a part of its territory in the Eastern Cordillera out of which Quesada and the Federal district were created—its area being reduced from 79,601 to 5060 sq. m., and its estimated population from 500,000 to 225,000. A considerable part of its area consists of plateaus enjoying a temperate climate and producing the fruits and cereals of the temperate zone, and another important part lies in the valley of the Magdalena and is tropical in character. The district of Fusagasugá in the southern part of this region is celebrated for the excellence of its coffee. The capital of the department was Facatativá (est. population, 7900), situated on the western margin of the sabana de Bogotá, 25 m. N.W. from that capital by rail. Other important towns are Caqueza, Sibaté, La Meza and Tocaima.

CUNEIFORM (from Lat. cuneus, a wedge), a form of writing, ex ensively used in the ancient world, especially by the Babylonians and Assyrians. The word "cuneiform" was first applied in 1700 by Thomas Hyde, professor of Hebrew in the university of Oxford, in the expression "dactuli pyramids seu cuneiformes," and it has found general acceptance, though efforts have been made to introduce the expression "arrow-headed" writing. The name "cuneiform" is fitting, for each character or sign is composed of a wedge (Γ or Τ), or a combination of wedges (Συ or αλατινια), written from left to right. The wedge is always pointed towards the right (Γ) or downwards (Σ) or aslant (Λ), or two may be so combined as to form an angle (Υ) called by German Assyriologists a Winkelhaken, a word sometimes adopted by English writers on the subject. The word cuneiform has passed into most modern languages, but the Germans use Kilschift (i.e. wedge-script) and the Arabs المسيرة (السيرة) or nail-writing.

In Persia, 40 m. N.E. of Shiraz, is a range of hills, Mount Rachmet, in front of which, in a semicircular form, rises a vast terrace-like platform. It is partly natural, but was walled up in front, levelled off and used as the base of great temples and palaces. The earliest European, at present known to us, who visited the site was a wandering friar Odoricus (about A.D. 1320), who does not seem to have noticed the inscriptions carved on the stones. These were first observed by Josaphat Barbaro, a Venetian traveller, about 1472. In 1621 the ruins were visited by Pietro della Valle, who was the first to copy a few of the signs, which he sent in a letter to a friend in Naples. His copy was not well made, but it served the useful purpose of directing attention to an unknown script which was certain to attract scholars to the problem of its decipherment. To this end it was necessary that complete inscriptions and not merely separate signs should be made accessible to European scholars. The first man to attempt to satisfy this need was Sir John Chardin, in whose volumes of travels published at Amsterdam in 1711 one of the small inscriptions found at the ruins of Persepolis was carefully and accurately reproduced. It was now plainly to be seen, as indeed others had surmised, that these inscriptions at Persepolis had been written in three languages, distinguished each from other by an increasing complexity in the signs with which they were written. The three languages have since been determined as Persian, Susian and Babylonian. But before the decipherment could begin it was necessary that all the available material should be copied and published. The honour of performing this great task fell to Carsten Niebuhr, who visited Persepolis in March 1765, and in three weeks and a half copied all the texts, so well that little improvement has been made in them since. When Niebuhr returned to Denmark he studied carefully the little inscriptions and convinced himself that the guesses of some of his predecessors were correct, and that the inscriptions were to be read from left to right. He observed that three systems of writing were discernible, and that these were always kept distinct in the inscriptions. He did not, however, draw the natural conclusion that they represented three languages, but supposed that the proud builders of Persepolis had written their inscriptions in threefold form. He divided the little inscriptions into three classes, according to the manner of their writing, calling them classes I., II. and III. He then arranged all those he had copied that belonged to class I., and by careful comparison decided that in them there were employed altogether but forty-two signs. These he copied out and set in order in one of his plates. This list of signs was so nearly complete and accurate that later study has made but slight changes in it. When
Niebuhr had made his list of signs he naturally enough decided that this language, whatever it might be, was written in alphabetic characters, a conclusion which later investigation has not overthrown. Beyond this Niebuhr was not able to go, and not even one sign revealed its secret to his inquiry. When, however, he had published his copies (in 1777) there were other scholars ready to take up the difficult task. Two scholars independently, Olav Tychsen of Rostock and Friedrich Münter of Copenhagen, began work upon the problem. Tychsen first observed that there occurred at irregular intervals in the inscriptions of the first class a wedge that pointed neither directly to the right nor downward, but inclined diagonally. This he suggested was the dividing sign used to separate words. This very simple discovery later became of great importance in the hands of Münter. Tychsen also correctly identified the alphabetic signs for "a," "d," "u," and "s," but he failed to decipher an entire inscription, chiefly perhaps because, through an error in history, he supposed that they were written during the Parthian dynasty (246 B.C.-A.D. 227). Münter was more fortunate than Tychsen in his historical researches, and this made him also more successful in linguistic attempts. He rightly identified the builders of Persepolis with the Achaemenian dynasty, and so located in time the authors of the inscriptions (538-465 B.C.). Independently of Tychsen he identified the oblique wedge as a divider between words, and found the meaning of the sign for "b." These may appear to be small matters, but it must be remembered that they were made without the assistance of any bilingual text, and were indeed taken bodily out of the gnomon which had settled upon these languages centuries before. They did not, however, bring us much nearer to the desired goal of a reading of any portion of the inscriptions. The whole case indeed seemed now perilously near a stalemate. New methods must be found, and a new worker, with patience, persistence, power of combination, insight, the historical sense and the feeling for archaeological indications.

In 1802 Georg Friedrich Grotefend (q.v.) was persuaded by the officers of Göttingen University to essay the task. He began with the assumption that there were three languages, and that of these the first was ancient Persian, the language of the Achaemenians, who had erected these palaces and caused these inscriptions to be written. For his first attempts at decipherment he chose two of these old Persian inscriptions and laid them side by side. They were of moderate length, and the frequent recurrence of the same signs in them seemed to indicate that their contents were similar. The method which he now pursued was so simple, yet so sure, as he advanced step by step, that there seemed scarcely a chance of error. Münter had observed in all the Persian texts a word which occurred in two forms, a short and a longer form. This word appeared in Grotefend's two texts in both long and short forms. Münter had suggested that it meant "king" in the short form and "kings" in the longer, and that when the two words occurred together the expression meant "king of kings." Not further, this word stood in such a relationship to the first line of both cases was followed by the same word. This second word Grotefend supposed to mean "great," the combined expression "king great," that is, "great king." All this found support in the phraseology of the lately deciphered Sassanian inscriptions, and it was plausible in itself. It must, however, be supported by definite facts, and furthermore each word must be separated into its alphabetic parts, every one of them identified, and the words themselves be shown to be philologically possible by the production of similar words in related languages. In other words, the archaeological method must find support in a philological method. To this Grotefend now devoted himself with equal energy. His method was as simple as before. He had made out to his own satisfaction the titles "great king, king of kings." Now, in the Sassanian inscriptions, the first word was always the king's name, followed immediately by "great king, king of kings," and Grotefend reasoned that this was probably true in his texts. But if true, then these two texts were set up by two different kings, for the names were not the same at the beginning. Furthermore the name with which his text No. I. began appears in the third line of text No. II., but in a somewhat longer form, which Grotefend thought was a genitive and meant "of N." It followed the word previously supposed to be "king" and another which might mean son (N king son), so that the whole expression would be "son of N king." From these facts Grotefend surmised that in these two inscriptions he had the names of three rulers, grandfather, father, and son. It was now easy to search the list of the Achaemenian dynasty and to find three names which would suit the conditions, and the three which he ventured to select were Hystaspes, Darius, Xerxes. According to his hypothesis the name at the beginning of inscription I. was Darius, and he was ready to translate his texts in the following order:

I. Darius, great king, king of kings ... son of Hystaspes.  
II. Xerxes, great king, king of kings ... son of Darius king.

The form which he provisionally adopted for Darius was Darievus; later investigation has shown that it ought really to be read as Daryavus, but the error was not serious, and he had safely secured at least the letters D, A, R, SII. It was a most wonderful achievement, the importance of which he did not realize, for in it was the key to the decipherment of three ancient languages. To very few men has it been given to make discoveries so important both for history and for philology.

To Grotefend it was, however, not given to translate a whole text, or even to work out all the words whose meaning he had surmised. Rasmus Christian Rask (1787-1832), who followed him, found the plural ending in Persian, which had baffled him; and Eugène Burnouf (1801-1852), by the study of a list of Persian geographical names found at Naksh-i-Rustam, discovered at a single stroke almost all the characters of the Persian alphabet, and incidentally confirmed the values already determined by his predecessors. At the same time as Burnouf, the eminent Sanskrit scholar Professor Christian Lassen (1800-1879), of Bonn, was studying the same list of names; and his results were published at the same time. The controversy which resulted as to priority of discovery may be here passed over while we sum up the results in general conclusions. Lassen may certainly claim in the final court of history that he discovered independently of Burnouf the values of at least six and possibly of eight signs. But in another respect he made very definite progress over Burnouf. He discovered that, if the system of Grotefend were rigidly followed, and to every sign were given the value Grotefend had assigned, some words would be left wholly or almost wholly without vowels; and therefore unpronounceable. As instances of such words he mentioned ÇPRD, THTGUS, KTPTUK, FRAISJM. This situation led Lassen to a very important discovery, towards which his knowledge of the Sanskrit alphabet did much to bring him. He came, in short, to the conclusion that the ancient Persian signs were not entirely alphabetic, but were at least partially syllabic, that is, that certain signs were used to represent not merely an alphabetic character like "a," but also a syllable such as "ba," "bi" or "bu." He claimed that he had successfully demonstrated that the sign for "a" was only used at the beginning of a word, or before a consonant, or before another vowel, and that in every other case it was included in the consonant sign. Thus in the inscription No. I. in the second line the signs should be read VA-Za-RA-KA. This was a most important discovery, and may be said to have revolutionized the study of these long puzzling texts.

During the entire time of this slow process of decipherment, from the first essays of Grotefend in 1802 until the publication of Lassen's book in 1836, there were more sceptics than believers in the results of the deciphering process. Indeed the history of all forms of decipherment of unknown languages shows that scepticism concerning them is far more prevalent than credulity or even a too ready acceptance. There was need for a man of another people, of different training and a fresh and unbiased mind, to put the capstone upon the decipherment, and he was already at work when Lassen's important researches appeared.
Major (afterward Sir) Henry Rawlinson had gone out to India, in the service of the East India Company, while still a boy. There, he had learned Persian and several of the Indian vernaculars. That was not the sort of training that had prepared Grotefend, Burnouf or Lassen, but it was the kind that the early travellers and copyists had enjoyed. In 1833 young Rawlinson went to Persia, to work with other British officers in the reorganization of the Persian army. While engaged in this service his attention was drawn to the ancient Persian cuneiform inscriptions. In 1835 he copied with great care the texts at Hamadan, and began their decipherment. Of all the eager work which had been going on in Europe he knew little. It is no longer possible to ascertain when he gained his first information of Grotefend's work, for Norris, the secretary of the Royal Asiatic Society, has left us no record of when he began to send notices of the German work. Whenever it was, there seems to be no doubt that Rawlinson worked independently for a time. His method was strikingly like Grotefend's. He had copied two trilingual inscriptions, and recognized at once that he had three languages before him. In 1839 (Journal of the Royal Asiatic Society, x. pp. 5-6) he thus wrote of his method: “When I proceeded... to compare and interline the two inscriptions (or rather the Persian columns of the two inscriptions, for, as the compartments exhibiting the inscriptions in the Persian language occupied the principal place in the tablets, and were engraved in the least complicated of the three classes of cuneiform writing, they were naturally first submitted to examination) I found that the characters coincided throughout, except in certain particular groups, and it was only reasonable to suppose that the grounds which were thus brought out and individualized must represent proper names. I further remarked that there were but three of these distinct groups in the two inscriptions; for the group which occupied the second place in one inscription, and which, from its position, suggested the idea of its representing the name of the father of the king who was there commemorated, corresponded with the group which occupied the first place in the other inscription, and thus not only served determinately to connect the two inscriptions together, but, assuming the groups to represent proper names, appeared also to indicate a genealogical succession. The natural inference was that in these three groups of characters I had obtained the proper names belonging to three consecutive generations of the Persian monarchy; and it so happened that the first three names of Hystaspes, Darius and Xerxes, which I applied at hazard to the three groups, according to the succession, proved to answer in all respects satisfactorily and completely to the facts then identified.”

Rawlinson next work was the copying of the great inscription of Darius on the rocks at Behistun (q.v.). He had first seen it in 1835, and as it was high up on the rocky face, and apparently inaccessible, he had studied it by means of a field-glass. He was not able to copy the whole of the Persian text, but in 1837, when he was more skilled in the script, he secured more of it. In the next year he forwarded to the Royal Asiatic Society of London his translation of the first two paragraphs of the Persian text, containing the name, titles and genealogy of Darius. This was little less than a tour de force, for it must be remembered that this had been accomplished without the knowledge of other ancient languages which his European competitors had enjoyed. The translation, received in London on the 14th of March, made a sensation, and a transcript sent in April to the Asiatic Society of Paris secured him an honorary membership in that distinguished body. He was now known, and many made haste to send him copies of everything important which had been published in Europe. The works of Burnouf, Niebuhr, leBrun and Porter came to his hands, and with such assistance he made rapid progress, and in the winter of 1838-1839 his alphabet of ancient Persian was most complete. In 1839 he was in Bagdad, his work written out and almost ready for publication. But he delayed, hoping for more light, and revising sign by sign with exhaustive patience. He expected to publish his preliminary memoir in the spring of 1840, when he was suddenly sent to Afghanistan as political agent at Kundahar. Here he was too busily engaged in war administration to attend to his favourite studies, which were not resumed until 1843 when he returned to Bagdad. There he received fresh copies and corrections of the Persepolis inscriptions which had been made by Westergaard, and later made a journey to Behistun to perfect his own copies of the texts which had formed the basis of his own first study. At last, after many delays and discouragements, he published, in 1846, in the Journal of the Royal Asiatic Society, his memoir, or series of memoirs, on the ancient Persian inscriptions, in which for the first time he gave a nearly complete translation of the Persian text of Behistun. In this one publication Rawlinson attained imperishable fame in Oriental research. His work had been carried on under greater difficulties than those in the path of his European colleagues, but he had surpassed them all in the making of an intelligible and connected translation of a long inscription. He had indeed not done it without assistance from the work of Burnouf, Grotefend and Lassen, but when all allowance is made for these influences his fame is not diminished nor the extent of his services curtailed. His method was adopted before he knew of Lassen's work. That two men of such different training and of such opposite types of mind should have lighted upon the same method, and by it have attained the same results, confirmed in the eyes of many the truth of the decipherment.

The work of the decipherment of the old Persian texts was now complete for all practical purposes. But in 1846 Westergaard published a paper read before the Royal Irish Academy by the Rev. Edward Hincks of Killyleagh, County Down, Ireland, whose keen criticisms of Lassen's work, and original contributio to the definite settlement of syllabic values, may be regarded as closing the period of decipherment of Persian cuneiform writing.

The next problem in the study of cuneiform was the decipherment of the second language in each of the trilingual groups. The first essay in this difficult task was made in 1844 by Niels Louis Westergaard. His method was very similar to that used by Grotefend in the decipherment of Persian. He selected the names of Darius, Hystaspes, Persians and others, and compared them with their equivalents in the Persian texts. By this means he learned a number of signs, and sought by their use in other words to spell out syllables or words whose meanings were then ascertained by conjecture or by comparison. He estimated the number of characters at eighty-two or eighty-seven, and judged the writing to be partly alphabetic and partly syllabic. The language he called Median, and classified it in "the Scythian, rather than in the Japhetic family." The results of Westergaard's work, which was published in 1845, were cast in incisive criticism by Hincks, who made a distinct gain in the problem. It next passed to the hands of de Saulcy, who was able to see farther than either. But the matter moved with difficulty because the copied texts were not accurate. By the generosity of Sir Henry Rawlinson his super copie of the Behistun text, second column, were placed in the hands of Mr Edwin Norris, who was able in 1852 to present a paper to the Royal Asiatic Society deciphering nearly all of it. Mordtmann followed him, naming the language Susian, which was met with general acceptance and was not displaced by the name Amardian, suggested by A. H. Sayce in two papers which otherwise made important contributions to the subject. With his contributions the problem of decipherment of Susian may be considered as closed. The latter workers could only be builders on foundations already laid.

The decipherment of the third of the three languages found at Persepolis and Behistun followed quickly on the success with Susian. The first worker was Isadore Lüwenstern, who made out the words for "king" and "great" and the sign for the plural, but little more. The first really great advance was made by Hincks in 1846 and 1847. In these he determined successfully the values of several signs, settled the numerals, and was apparently on the high road toward the translation of entire Assyrian text. He was, however, too cautious to proceed so far, and the credit of first translating a short Assyrian text belongs to Longperier, who in 1847 published the following as the translation of an entire text: "Glorious is Sargon, the great king, the (. . .) king, king of kings, king of the land of Assyria."
It was nearly all correct, but it advanced our knowledge but slightly because it did not give the forms of the words—because (to put it in another way) he was not able to transcribe the Assyrian signs. This was the great problem. In the Persian texts there were but forty-four signs, but in the third column of the Persepolis texts Grotefend had counted one hundred and thirty different characters, and estimated that in all the Babylonian texts known to him there were about three hundred different signs, while Botta discovered six hundred and forty-two in the texts found by him at Khorsabad. That was enough to make the stoutest heart quail, for a meaning must be found for every one of these signs. There could not be so many syllables, and it was, therefore, quite plain that the Babylonian language must have been written in part at least in ideograms. But in 1851 Rawlinson published one hundred and twelve lines of the Babylonian column from Behistun, accompanied by an interlinear translation into Roman characters, and a translation into Latin. That paper, added to Hinck's still more acute detail studies, brought to an end the preliminary decipherment of Babylonian. There were still enormous difficulties to be surmounted in the full appreciation of the complicated script, but these would be solved by the combined labours of many workers.

The cuneiform script had its origin in Babylonia and its inventors were a people whom we call the Sumerians. Before the Semitic Babylonians conquered the land it was inhabited by a people of unknown origin variously classified, by different scholars, with the Ural-Altaic or, even with the Indo-European family, or as having blood relationship with both. This people is known to us from thousands of cuneiform inscriptions written entirely in their language, though our chief knowledge of them was for a long time derived from Sumerian inscriptions with interlinear translations in Assyrian. Their language is called Sumerian (li-ia-an Su-me-ri) by the Assyrians (Br. Mus. 81-7-27, 130), and its characteristics are being slowly developed by the elaborate study of the immense literature which has come down to us. In 1884 Halévy denied the existence of the Sumerian language, and claimed that it was merely a cabalistic script invented by the priests of the Semites. His early success has not been sustained, and the very majority of scholars have ceased to doubt the existence of the language.

The Sumerians developed their script from a rude picture-writing, some early forms of which have come down to us. In course of time they used the pictures to represent sounds, apart from ideas. They wrote first on stone, and when clay was adopted soon found that straight lines in soft clay when made by a single pressure of the stylus tend to become wedges, and the pictures therefore lost their character and came to be more conventional groups of wedges. Some of these wedge-shaped signs are of such character that we are still able to recognize or re-construct the original picture from which they came. The Assyrian sign 𒅗, which means heaven, appears in early texts in the form 𒅅 in which its star-like form is quite evident (star = heaven) and from which the linear form 𒅗 may be not improbably pre-supposed. A number of other cases were enumerated by the Assyrians themselves (see Cuneiform Texts from Bab. Tob. in Brit. Museum, vol. i., 1885), and there can be no reasonable doubt that this is the origin of the script. The number of the original picture-signs cannot have been great, but the development of new signs never ceased till the cuneiform script passed wholly from use. The simplest form of development was doubling, to express plurality or intensity. After this came the working of two signs into one; thus 𒅗 "water," when placed in 𒅗𒅗 "mouth" gave the new sign 𒅗𒅗 to "drink," and many others. Other signs were formed by the addition of four lines, either vertically or horizontally, to intensify the original meaning. Thus, for instance, the old linear sign 𒅗 means dwelling, but with four additional signs, thus 𒅗𒅗𒅗𒅗, it means "great house!"

This sign gradually changed in form until it came to 𒅗𒅗𒅗𒅗. This method of development was called by the Sumerians ginsu, and signs thus formed are now commonly called by us, ginsu signs. They number hundreds and must be reckoned with in our study of the script development, though perhaps recent scholars have somewhat exaggerated their importance. The process of development is obscure and must always remain so.

The script as finally developed and used by the Assyrians is curious and complicated, and very ill adapted to the sounds of the Semitic alphabet. It has (1) simple syllables, consisting of one vowel and a consonant, or a vowel by itself, thus 𒅗 “a,” 𒅗𒅗 ab, 𒅗𒅗 ib, 𒅗𒅗 ub, 𒅗𒅗 ba, 𒅗𒅗 bi, 𒅗𒅗 bu. In addition to these the Assyrian had also (2) compound syllables, such as 𒅗𒅗 bit, 𒅗𒅗 šal, and (3) ideograms, or signs which express an entire word, such as 𒅗𒅗 belu, lady, 𒅗𒅗 abu, father. The difficulty of reading this script is enormously increased by the fact that many signs are polyphonic, i.e. they may have more than one syllabic value and also be used as an ideogram. Thus the sign 𒅗 has the ideographic values of matu, land, šadu, mountain, kashadu, to conquer, naphachu, to arise (of the sun), and also the syllabic values kur, mod, mat, šad, šat; lat, nad, nat, kin and gin. This method of writing must lead to ambiguity, and this difficulty is helped somewhat by (4) determinatives, which are signs intended to indicate the class to which the word belongs. Thus, the 𒅗 is placed before names of persons, and 𒅗 (the ideogram for matsu, country, and šadu, mountain) is placed before names of countries and mountains, and 𒅗 (iliu, god) before the names of gods.

The cuneiform writing, begun by the Sumerians in a period so remote that it is idle to speculate concerning it, had a long and very extensive history. It was first adopted by the Semitic Babylonians, and as we have seen was known for a thousand years, developed, and may almost be said to have been invented. The inscriptions are written in it from circa 4500 B.C. to the 1st century B.C. From their hands it passed to the Assyrians, who simplified some characters and conventionalized many more, and used the script during the entire period of their national existence from 1500 B.C. to 607 B.C. From the Babylonian by a slow process of evolution the much simplified Persian script was developed, and with the Babylonian is also to be connected the Susian, less complicated than the Babylonian, but less simple than the Persian. The Chaldaic or Chaldeans, who lived about Lake Van, also adopted the cuneiform script with values of their own, and expressed a considerable literature in it. The discovery in 1887 of the Tell-el-Amarna tablets in upper Egypt showed that the same script was in use in the 15th century B.C., from Elam to the Mediterranean and from Armenia to the Persian Gulf for purposes of correspondence. There is good reason to expect the discovery of its use by yet other peoples. It was one of the most widely used of all the forms of ancient writing.

Biography.—The history of the decipherment may be further studied in R. W. Rogers, History of Babylonia and Assyria, vol. i. (N.Y. and London, 1900); and in A. J. Booth, The Discovery and Decipherment of the Trilingual Cuneiform Inscriptions (London, 1902), which is very exhaustive and accurate. The Sumerian question may best be studied in F. H. Weissbach, Die Sumerische Frage (Leipzig, 1898), and Charles Fossey, Manuel d'Assyriologie, tome i. (Paris, 1904). For development and characteristics, see Friedrich Delitzsch, Die Entstehung des ältesten Schriftsystems (Leipzig, 1897); Paul Tossanne, Les langues sumériennes dérivées (Paris, 1905).

CUNEO (Fr. Cuny), a town and episcopal see of Piedmont, Italy, the capital of the province of Cuneo, 55 m. by rail S. of Turin, 1722 ft. above sea-level. Cuneo lies on the railway from Turin to Ventimiglia, which farther on passes under the Col of Tenda (tunnel 5 m. long). It is also a junction for Mondovi and Saluzzo, and has steam tramways to Borgo S. Dalmazzo, Boves, Saluzzo and Dronero. Pop. (1901) 15,412 (town), 26,870 (commune). Its name ("wedge") is due to its position on a hill between two streams, the Stura and the Gesso, with fine views of the mountains. The Franciscan church, now converted into a military storehouse, belongs to the 12th century, but there are no other buildings of special interest. The fortifications have
been converted into promenades. Cuneo was founded about 1130 by refugees from local baronial tyranny, who, after the destruction of Milan by Barbarossa, were joined by Lombards. In 1382 it swore fealty to Amedeus VI., duke of Savoy. It was an important fortress, and was ceded by the treaty of Cherasco (1796), with Ceva and Tortona, to the French. In 1796 it was taken after ten days' bombardment by the Austrian and Russian armies, and, in 1800, after the victory of Marengo, the French demolished the fortifications.

**Cuneus (Latin for "wedge"; plural, cunei),** the architectural term applied to the wedge-shaped divisions of the Roman theatre separated by the scaenae or stairways; see Vitruvius v. 4.

**Cunitz, Maria (c. 1610–1664),** Silesian astronomer, was the eldest daughter of Dr. Heinrich Cunitz of Schwineitz, and the wife (1630) of Dr. Elias von Löwen, of Pitschen in Silesia—both of them men of learning and distinction. From her universal accomplishments she was called the "Silesian Pallas," and the publication of her work, *Urania propitia* (Oels, 1650), a simplification of the Rudolphine Tables, gained her a European reputation. It was composed at the village of Lugnitz, close by the convent of Globolka-Posen, where, with her husband, she had taken refuge after the battle of the Thirty Years' War, and dedicated to the emperor Frederick III. The author became a widow in 1661, and died at Pitschen on the 24th of August 1664.

**Cunningham, Alexander (c. 1655–1730),** Scottish classical scholar and critic, was born in Ayrshire. Very little is known of his uneventful life. It is probable that he completed his education at Leiden or Utrecht. He was tutor to the son of the first duke of Queensberry, through whose influence he was appointed professor of civil law in the university of Edinburgh. In 1710, the Edinburgh magistrates, regarding the university patronage as their privilege, appointed another professor, ignoring the appointment of Cunningham, who had been installed in the office for at least ten years. Cunningham thereupon left England for the Hague, where he resided until his death. He is chiefly known for his edition of Horace (1721) with notes, mostly critical, which he dedicated to Dr. Robert successive volumes upon Richard Bentley's notes and emendations. They marked him as one of the most able critics of Bentley's (in many cases) rash and tasteless conjectural alterations of the text. Cunningham also edited the works of Virgil and Phaedrus (together with the *Sententiae* of Publius Syrus and others). He had also been engaged for some years in the preparation of an edition of the Pindarics and of a work on Christian evidences.

Life by D. Irving in *Lives of Scottish Writers* (1839).

The above must not be confused with Alexander Cunningham, British minister to Venice (1715–1720), a learned historian and author of *The History of Great Britain* (from 1688 to the accession of George I.), originally written in Latin and published in an English translation after his death.

**Cunningham, Allan (1784–1842),** Scottish poet and man of letters, was born at Keir, Dumfriesshire, on the 7th of December 1784, and began life as a stone mason's apprentice. His father was a neighbour of Burns at Ellisland, and Allan with his brother James visited James Hogg, the Ettrick shepherd, who became a friend to both. Cunningham contributed some songs to Roche's *Literary Recreations* in 1807, and in 1809 he collected old ballads for Robert Hartley Cromek's *Remains of Nithsdale and Galloway Song*; he sent in, however, poems of his own, which the editor inserted, even though he may have suspected their real authorship. In 1810 Cunningham went to London, where he supported himself chiefly by newspaper reporting till 1814, when he became clerk of the works in the studio of Francis Chantry, retaining this employment till the sculptor's death in 1841. He meanwhile continued to be busily engaged in literary work. Cunningham's prose is often spoiled by its misplaced and too ambitious rhetoric; his verse also is often over-ornate, and both are full of mannerisms. Some of his songs, however, hold a high place among British lyrics. "A Wet Sheet and a Flowing Sea" is one of the best of our sea-songs, although written by a landsman; and many other of Cunningham's sea songs will bear comparison with it. He died on the 30th of October 1842.

He was married to Jean Walker, who had been servant in a house where he lived, and had five sons and one daughter. **Joseph Davey Cunningham (1812–1851)** entered the Bengal Engineers, and is known by his *History of the Sikhs* (1840). **Sir Alexander Cunningham (1814–1893)** also entered the Bengal Engineers; attaining the rank of major-general; he was director general of the Indian Archaeological Survey (1870–1885), and wrote an *Ancient Geography of India* (1871) and *Coins of Medical India* (1804). Peter Cunningham (1816–1860) published several topographical and biographical studies, of which the most important are his *Handbook of London* (1849) and *The Life of Drummond of Hawthornden* (1833). Francis Cunningham (1820–1875) joined the Indian army, and published editions of Ben Jonson (1871), Marlowe (1870) and Massinger (1871).

The works of Allan Cunningham include *Lives of the Most Eminent British Poets* (1820–1823); *Stuart and Albion* (1829–1833); *Sir Marmaduke Maxwell* (1830), a dramatic poem; *Traditions and Tales of the Peasantry* (1822), several novels (Paul Jones, *Sir Michael Scott, Lord Roldam*); the *Maid of Elwar*, a sort of epic romance; *The Songs of Scotland through all the Ages* (1828); *English Historical and Critical Dissertations* (1833); *The Life of the Great General Wolfe* (1823); an edition of *The Works of Robert Burns*, with notes and a life containing a good deal of new material (1834); *Biographical and Critical Dissertations* affixed to Major's *Gallery of Poets*; and *Life, Journals and Correspondence of Sir David Wilkie*, published in 1843. An edition of his Poems and Songs was issued by his son, Peter Cunningham, in 1847. **Cunningham, William (1803–1851),** Scottish theologian and ecclesiast, was born at Hamilton, in Lanarkshire, on the 2nd of October 1805, and educated at the university of Edinburgh. He was licensed to preach in 1828, and in 1830 was ordained to a collegiate charge in Greenock, where he remained for three years. In 1834 he was transferred to the charge of Trinity College parish, Edinburgh. His removal coincided with the commencement of the period known in Scottish ecclesiastical history as the Ten Years' Conflict, in which he was destined to take a leading share. In the stormy discussions and controversies which preceded the Disruption the weight and force of his intellect, the keenness of his logic, and his firm grasp of principle made him one of the most powerful advocates of the cause of spiritual independence; and he was generally recognized as one of three to whom mainly the existence of the Free Church is due, the others being Chalmers and Candlish. On the formation of the Free Church in 1843, Cunningham was appointed professor of church history and divinity in the New College, Edinburgh, of which he became principal in 1847 in succession to Thomas Chalmers. His career was very successful, his controversial sympathies combined with his evident desire to be rigidly impartial qualifying him to be an interesting delineator of the more stirring periods of church history, and a skilful disseminator of the knotty points in theological polemics. In 1850 he was appointed moderator of the General Assembly. He had received the degree of D.D. from the university of Princeton in 1842. He died on the 14th of December 1861. He was one of the founders of the Evangelical Alliance. A theological lecturer at the New College, Edinburgh, was endowed in 1862, to be known as the Cunningham lectureship.

**Cunningham, William (1839–1909)**, English economist, was born at Edinburgh on the 20th of December 1839. Educated at Edinburgh Academy and University and Trinity College, Cambridge, he graduated 1st class in the Moral Science tripos in 1873, and in the same year took holy orders. He was university lecturer in history from 1884 to 1891, in which year he was appointed professor of economics at King's College, London, a post which he held until 1897. He was lecturer in economic history at Harvard University (1890), and Hulsean lecturer at Cambridge (1885). He became vicar of Great St Mary's, Cambridge, in 1887, and was made a fellow of the British Academy. In 1906 he was appointed archdeacon of Ely. Dr Cunningham's
CUP—CUPBOARD

Growth of English Industry and Commerce during the Early and Middle Ages (1850; 4th ed., 1905) and Growth of English Industry and Commerce in Modern Times (1882; 3rd ed., 1905) are the standard works of reference on the industrial history of England. He also wrote The Use and Abuse of Money (1891; Alien Immigration (1893); Western Civilization in its Economic Aspect in Ancient Times (1898), and in Modern Times (1900), and The Rise and Decline of Free Trade (1905). Dr. Cunningham's eminence as an economic historian gave special importance to his attitude as one of the leading supporters of Mr. Chamberlain from 1903 onwards in criticizing the English free-trade policy and advocating tariff reform.

CUP (in O.E. cuppe; generally taken to be from Late Lat. cupa; a variant of Lat. cupa, a cask, cf. Gr. κάσακος), a drinking vessel, usually in the form of a half a sphere, with or without a foot or handles. The footless type with a single handle is preserved in the ordinary tea-cup. The cup on a stem with a base is the usual form taken by the cup as used in the celebration of the eucharist, to which the name "chalice" (Lat. calix, Gr. κάλαξ, a goblet) is generally given. (See DRINKING VESSELS and PLATE.)

CUPAR, a royal, municipal and police burgh, and capital of the county of Fife, Scotland, 11 m. W. by S. of St. Andrews, by the North British railway. Pop. (1901) 4,511. It is situated on the left bank of the Eden, in the east of the Howe (Hollow) of Fife, and is sometimes written Cupar-Fife to distinguish it from Cupar-Angus in Perthshire. Among the chief buildings are the town hall, county buildings, corn exchange, Duncan Institute, cottage hospital, Union Street Hall and the Bell-Baxter school. The school, formerly called the Madras Academy, was originally endowed (1852) by Dr. Bell, founder of the Madras system of education, but, having been enriched at a later date by a bequest of Sir David Baxter (1873), it was afterwards called the Bell-Baxter school. The Mercat Cross stands at "the Cross" in the main street, where it was set up in 1897, having been removed from Hilltarvit, an eminence in the neighbourhod of Cupar, on the western slope of which, at Garlumbank, the truce was signed between Mary of Guise and the lords of the Congregation. In the parish, but at a distance from the town, are the Fife and Kinross asylum and the Adamson institute, a holiday home for poor children from Leith.

The town received its charter in 1356 from David II., and, being situated between Falkland and St. Andrews, was constantly visited by Scottish sovereigns, James VI., holding his court there for some time in 1593. The site of the 12th-century castle, one of the strongholds of the Macduffs, was near the site of the town, but Fife, which is occupied by a public school. On the esplanade in front of Macduff Castle, still called the Playfield, took place in 1552 one of the first recorded performances of Sir David Lindsay's Ane Satyre of the Three Estaitis (1540); his Tragedy of the Cardinal (1547), referring to the murder of Beaton, was being performed there. Sir David sat in the Scottish parliament as commissioner for Cupar, his place, the Mount, being within 3 m. of the west of the town. Lord Chancellor Campbell (1815-1861) was a native of Cupar.

Cupar is an agricultural and legal centre. Its chief industry is the manufacture of linen, and tanning is carried on. At Cupar Muir, 1½ m. to the west, there are a sandstone quarry and brick works. The town has also some repute for the quality of its printing, both in black and colour. This was largely due to the Tullis press, which produced about the beginning of the 19th century editions of Virgil, Horace and other classical writers, under the recension of Professor John Hunter of St. Andrews, which were highly esteemed for the accuracy of their typography. Cupar belongs to the St. Andrews district group of burghs for returning one member to parliament, the other constituents being Crail, the two Anstruthers, Kilrenny, Pittenweem and St. Andrews.

There are several interesting places within a few miles. To the north-east is the parish of Dairsie, where one of the few parliaments that ever met in Fife assembled in 1335. The castle in which the senate sat was also the residence for a period of Archbishop Spottiswood, who founded the parish church in 1621. Two miles and a half north of Dairsie is situated Kilmany, which was the first charge of Thomas Chalmers. He was ordained to it in May 1683 and held it for two years, after which the Covenanters, who was a passive assister at the assassination of Archbishop Sharp, belonged to this parish, his place being named Rathillet. After his execution at Edinburgh (1680) one of his hands was buried at Cupar, where a monument inscription records the circumstances of his death. To the west of Kilmany lies Creich, where Alexander Henderson (1583-1646), the Covenanting divine and diplomatist, and John Sage (1652-1711), the non-juring archbishop of Glasgow, were born. Henderson took a keen interest in education and gave the school at Creich a small endowment. Some 3 m. to the south-west of Cupar is Cults, where Sir David Wilkie, the painter, was born. His father was minister of the parish, and Pitlessie, the fair of which provided the artist with the subject of the first picture in which he showed direct promise, lies within a mile of the manse. In the sandstone of Dura Den, a ravine on Ceres Burn, 3 m. E. of Cupar, have been found great quantities of fossils of ganoid fishes. The rocks belong to the Upper Old Red Sandstone.

CUPBOARD, a fixed or movable closet usually with shelves. As the name suggests, it is a descendant of the credence or buffet, the characteristic of which was a series of open shelves for the reception of drinking vessels and table requisites. After the word lost its original meaning—and down to the end of the 16th century we still find the expression "on the cupboard"—this piece of furniture was, as it to some extent remains, movable, but it is now most frequently a fixture designed to fill a corner or recess. Throughout the 18th century the cupboard was a distinguished domestic institution, and the housewife found her chief joy in accumulating cupboards full of china, glass and preserves. With the exception of a very few examples of fine ecclesiastical cupboards which partook chiefly of the nature of the armoire in that they were intended for the storage of vestments, the so-called court-cupboard is perhaps the oldest form of the contrivance. The derivation of the expression is somewhat obscure, but it is generally taken to refer to the French word court, short. This particular type was much used from the Elizabethan to the end of the Caroline period. It was really a sideboard with small square doors below, and a recessed superstructure supported upon balusters. Of these many examples remain. Less frequent is the livery cupboard, the meaning of which may be best explained by the following quotation from Spenser's Account of the State of Ireland:

"What livery is we by common use in England know well enough, namely, that it is an allowance of horse-meat, as they commonly use the word stabling, as to keep horses at livery; the which word I guess is derived of livernger or delivering forth their nightly food; so in great houses the livery is said to be served up for all night—that is, their evening allowance for drink." The livery cupboard appears usually to have been placed in bedrooms, so that a supply of food and drink was ready at a moment when a long and feudal feasting separated the last meal of the day from the bed; or even after the main meal. The livery cupboard was often small enough to stand upon a sideboard or cabinet, and had an open front with a series of turned balusters. It was often used in churches to contain the loaves of bread doled out to poor persons under the terms of ancient charters. They were then called doe cupboards; there are two large and excellent examples in St. Alban's Abbey. The butter, or bread and cheese cupboard, was a more ordinary form, with the back and sides bored with holes, sometimes in a geometrical pattern, for the admission of air to the food within. The corner cupboard, which is in many ways the most pleasing and artistic form of this piece of furniture, originated in the 18th century, which as we have seen was the golden age of the cupboard. It was often of oak, but more frequently of mahogany, and had either a solid or a glass front. The older solid-fronted pieces are fixed to the wall half-way up, but those of the somewhat more modern type, in which there is much glass, usually have a wooden base with glazed superstructure. Most corner cupboards are attractive.
in form and treatment, and many of them, inlaid with satinwood, ebony, holly or box, are extremely elegant.

CUPID (Cupid, "desire"), the Latin name for the god of love, Ergo, in Greek, Cupid is generally identical with Amor. The idea that the god of love in Roman poetry is due to the influence of Alexandrian poets and artists, in whose hands he degenerated into a mischievous boy with essentially human characteristics. His usual attribute is the bow. For the story of Cupid and Psyche, see under Psyche.

CUPOLA (ital., from Lat. cupula, small cask or vault, cupa, tub), a term in architecture, for a spherical or spheroidal covering to a building, or to any part of it. In fortification the word is used of a form of armoured structure, in which guns or howitzers are mounted. It is a low flat turret resembling an overturned saucer and showing little above the ground except the muzzles of the guns. See for details and illustrations Fortification and Siegecraft; also Ordnance.

CUPPING. The operation of cupping is one of the methods that have been adopted by surgeons to draw blood from an inflamed part in order to relieve the inflammation. The skin is washed and dried; a glass cup with a rounded edge is then firmly applied, after the air in it has been heated; the cooling of the air causes the formation of a partial vacuum, and the blood is thus drawn from the neighbouring parts to the skin under the cup. Either the blood is drawn from the patient's body through a number of small wounds which are made in the skin, with a special instrument, before the cup is applied; or the cup is simply applied to the unbroken skin and the blood drawn into the subcutaneous tissue within the circumference of the cup. The result of both methods is the same,—namely, a withdrawal of blood locally from the inflamed part. The former is called moist cupping, the latter dry cupping. This operation has naturally declined in vogue with the obsolescence of blood-letting as a remedy.

CUPRA, the name of two ancient Italian municipia in Picenum. 1. Cupra Maritima (Civita di Marano near the modern Cupra Marittima), on the Adriatic coast, 48 m. S.S.E. of Ancona, erected in the neighbourhood of an ancient temple of the Sabine goddess Cupra, which was restored by Hadrian in A.D. 127, and probably (though there is some controversy on the point) occupied the site of the church of S. Martino, some way to the south, in which the inscription of Hadrian exists. At Civita the remains of what was believed to be the temple were more probably those of the forum of the town, as is indicated by the discovery of fragments of a calendar and of a statue of Hadrian. Some statuettes of Juno were also among the finds. An inscription of a water reservoir erected in 7 B.C. is also recorded. But the more ancient Picene town appears to have been situated near the hill of S. Andrea, a little way to the south, where pre-Roman tombs have been discovered.

See C. Hulsen in Pauly-Wissowa, Realencyclopadie (Stuttgart, 1901), iv. 1760; G. Speranza, Il Piceno (Ascoli Piceno, 1900), i. 119 seq.

2. Cupra Montana, 10 m. S.W. of Asis (mod. Jesi) by road. The village, formerly called Massaccio, has assumed the name of its site. Its name is fixed by inscriptions—cf. Th. Mommsen in Corp. Inscrip. Lat. ix. (Berlin, 1883), p. 543; and various ruins, perhaps of baths, and remains of subterranean aqueducts have been discovered near the church of S. Eleuterio.

See F. Menicucci in G. Colucci, Antichita Picene, xx. (1793).

CUPRITE, a mineral consisting of cuprous oxide, Cu₂O, crystallizing in the cubic system, and forming an important ore of copper, of which element cuprite contains 88-8%.

The name cuprite (from Lat. cuprum, copper) was given by W. Haidinger in 1845; earlier names are red copper ore and ruby copper, which at once distinguish this mineral from the other native copper oxides—cupric oxide—known as black copper ore or melaconite. Well-developed crystals are of common occurrence; they usually have the form of the regular octahedron, sometimes in combination with the cube and the rhombic dodecahedron. A few Cornish crystals have been observed with faces of a form {411} known as the pentagonal isositetrahedron, since it is bounded by twenty-four irregular pentagons. In this class of cubic crystals there are no planes or centre of symmetry, but the full number (thirteen) of axes of symmetry; it is an example of a truly tetrahedral class, and cuprite affords the best example of this type of symmetry. The etching figures do not, however, conform to this lower degree of symmetry, nor do crystals of cuprite rotate the plane of polarization of plane-polarized light. The colour of the mineral is cochineal-red, and the lustre brilliant and adamantine to sub-metallic in character; crystals are often translucent, and show a crimson-red colour by transmitted light. On prolonged exposure to light the crystals become dull and opaque. The streak is brownish-red. Hardness 3½; specific gravity 6-0; refractive index 2-85.

Compact to granular masses also occur, and there are two curious varieties—chalocritiche and tile-ore—which require special mention. Chalocritiche (from Gr. χαλός, copper, and τρίχα, τριχος, hair) or "plush copper ore" is a capillary form with a rich carmine colour and silky lustre; the delicate hairs are loosely matted together, and each one is an individual crystal enormously elongated in the direction of the diagonal or the edge of the cube. Tile-ore (Ger. Ziegeleize) is a soft earthy variety of a brick-red to brownish-red colour; it contains admixed limonite, and has been formed by the alteration of chalcopyrite (copper and iron sulphide).

Cuprite occurs in the upper part of copper-bearing lodes, and is of secondary origin, having been produced by the alteration of copper sulphides. Beautifully crystallized specimens were formerly found in Wheal Gorland and Wheal Unity at Gwennap, and in Wheal Phoenix near Liskeard in Cornwall; they also occur in the copper mines of the Urals, and in Arizona. Isolated crystals bounded by faces on all sides, and an inch or more in diameter, are found embedded in a soft white clay at Chessy near Lyons; they are usually altered on the surface, or throughout, to malachite. Chalocritiche comes from Wheal Phoenix and Fowey Consols mine in Cornwall, and from Morenci in Arizona; tile-ore from Bogoslovsk in the Urals, Atacama in South America, and other localities. Small crystals of cuprite, together with malachite, azurite and cerussite, are sometimes found encrusting ancient objects of copper and bronze, such as celts and Roman coins, which have for long periods remained buried in the soil. Artificially formed crystals have been observed in furnace products.

CUPULIFERA, a botanical order, or, in recent arrangements, a group of orders, containing several familiar trees. The plants are trees or shrubs with simple leaves alternately arranged and small unisexual flowers generally arranged in catkins and pollinated by wind-agency. The generally one-seeded nut-like fruit is associated with the persistent often hardened or greatly enlarged bracts forming the so-called cupule which gives the name to the group. The group is subdivided as follows, and these subdivisions are now generally regarded either as distinct natural orders or the first two as sub-orders of one natural order.

Betuleae or Betulaceae. Female flowers arranged, two to three together on scale-like structures formed by the union of bracts, in catkins; ovary two-celled; fruit small, flattened, protected between the ripened scales of the catkin. Includes Betula (birch) and Alnus (alder).

Coryleae or Corylaceae. Female flowers in pairs, the bracts enlarging in the fruit to form a membranous cup (hazel), or a flat three-lobed structure (hornbeam). Ovary two-celled. Includes Corylus (hazel) and Carpinus (hornbeam).

Pagaceae (Cupuliferae in a restricted sense). Bracts forming a fleshy or hard cupule which envelops the one to several fruits. Ovary three-celled. Includes Quercus (oak), Pagus (beech), Castanea (sweet-chestnut).

Detailed accounts of the trees will be found under separate headings.
CURAÇAO, or CURAÇÂO, an island in the Dutch West Indies. It lies 40 m. from the north coast of Venezuela, in 12° N. and 69° W., being 40 m. long from N.W. to S.E., with an average width of 10 m. and an area of 212 sq. m. The surface is generally flat, but in the south-west there are hills attaining an elevation of 1200 ft. The shores are in places deeply indented, forming several natural harbours, the chief of which is that of St Anna on the south-west coast. Curaçao consists of eruptive rocks, chiefly diorite and diabase, and is surrounded by coral reefs. Streams are few and the rainfall is scanty, averaging only 16 in. per annum. Although the plains are for the most part arid wastes, sugar, aloes, tobacco and divi-divi are produced with much toil in the more fertile gilens. Salt, phosphates and cattle are exported. The commerce is mainly with the United States, and there is a large carrying trade with Venezuela. The famous Curacao liqueur (see below) was originally made on the island from a peculiar variety of orange, the Citrus Aurantium curassawiensis. Willemstad (pop. about 8000), on the harbour of St Anna, is the principal town. It bears a strong resemblance to a Dutch town, for the houses are built in the style of those at Amsterdam, and the narrow channel separating it from its western suburb Overzijde and the waters of the Waigat, which intersect it, recall the canals. The narrow entrance leading to the Schotdegat or Inner Harbour is protected by forts. The negroes of the island speak a curious dialect called Popapimento, composed of Spanish, Dutch, English and native words. Curacao gives name to the government of the Dutch West Indies, which consists of Aruba, an island lying W. of Curaçao, with an area of 69 sq. m. and a population of 9501; Buen Ayre, lying 20 m. N.E., with an area of 95 sq. m. and a population of 4926; together with St Eustatius, Saba and part of St Martin. The governor is assisted by a council of four members and a colonial council of eight members nominated by the crown. The island of Curaçao has a population of 30,119; and altogether the Dutch West Indies have a population of 51,603.

Curaçao was discovered by Höjeda about 1499 and occupied by the Spaniards in 1527. In 1634 it fell into the hands of the Dutch, who have held it ever since, except during the year 1798, and from 1806 to 1814 when it passed into the possession of Great Britain.

CURAÇAO, a liquor, chiefly manufactured in Holland. It is relatively simple in composition, the predominating flavour being obtained from the dried peel of the Curaçao orange. The method of preparation is in principle as follows. The peel is first softened by maceration; then a part of the softened peel is distilled with spirit and water, and the remainder is macerated in a portion of the distillate so obtained. After two or three days the infusion is strained and added to the remainder of the original distillate. This simple method is subject to variations in manufacture, and the addition of a small quantity of Jamaica rum, in particular, is said to much improve the flavour. Dry Curacao contains about 39½%, the sweet variety about 36% of alcohol. A lighter variety of Curaçao, made with fine brandy, is known as Curazao Grand Marnier.

CURASSOW (Cracinae), a group of gallinaceous birds forming one of the subfamilies of Cracidae, the species of which are among the largest and most splendid of the game birds of South America, where they may be said to represent the pheasants of the Old World. They are large, heavy birds, many of them rivalling the turkey in size, with short wings, long and broad tail, and strong bill. In common with the family to which they belong, they have the hind toe of the foot placed on a level with the others, thus resembling the pigeons, and unlike the majority of gallinaceous birds. With the exception of a single species found north of Panama, the curassows are confined to the tropical forests of South America, east of the Andes, and not extending south of Paraguay. They live in small flocks, and are arboreal in their habits, only occasionally descending to the ground, while always roosting and building their nests on the branches of trees. Their nests are neat structures, made of slender branches interlaced with stems of grass, and lined internally with leaves. They feed on fruits, seeds and insects. They are often tamed in several parts of South America, but have never been thoroughly domesticated anywhere. Large numbers of these birds were, according to K. J. Temminck, brought to Holland from Dutch Guiana towards the end of the 18th century, and so completely acclimatized and domesticated as to breed in confinement like ordinary poultry; but the establishments in which these were kept were broken up during the troubles that followed on the French Revolution. Their flesh is said to be exceedingly white and delicate, and this, together with their size and the beauty of their plumage, would make the curassows an important gain to the poultry yards of Europe, if they were not such bad breeders. The subfamily of curassows contains four genera and twelve species, all confined to South America, with the exception of Crax globiceps—a Central American species, which extends northward into Mexico. This bird is about 3 ft. in length, of a glossy black colour over the whole body, excepting the abdomen and tail coverts, which are reddish; the head is remarkable for the curiosity of its shape, and the middle of the crest bears a crest of feathers curled forward at the edge of a cap, which can be raised or depressed at will. The female is of a reddish-brown colour, although varying greatly in this respect, and was formerly described as a separate species—the red curassow. In another species, Crax incommoda, the greater part of the black plumage is beautifully varied with narrow transverse bars of white. The galeated curassow (Paruax galea) is peculiar in having a large blue tufted, hard and stony externally, but cellular within, and resembling a hen's egg in size and shape, situated at the base of the bill. It only appears after the first moulting, and is much larger in the male than in the female.

CURATE (from the Lat. curare, to take care of), properly a presbyter who has the care of souls within a parish. The term is used in this general sense in certain rubrics of the English Book of Common Prayer, in which it is applied equally to rectors and vicars as to perpetual curates. So, on the continent of Europe, it is applied in this sense to parish priests, as the Fr. curé, It. curato, Span. cura, &c. In a more limited sense it is applied in the Church of England to the incumbent of a parish who has no endowment of tithes, as distinguished from a perpetual vicar, who has an endowment of small tithes, which are for that reason sometimes styled vicarial tithes. The origin of such unendowed curacies is traceable to the fact that benefices were sometimes granted to religious houses pleno jure, and with liberty for them to provide for the cure; and when such appropriations were transferred to lay persons, being unable to serve themselves, the impoverished were required to nominate a clerk in full orders to the ordinary for his licence to serve the cure. Such curates, being not removable at the pleasure of the impoverished, but on due revocation of the licence of the ordinary, came to be entitled perpetual curates. The term "curate" in the present day is almost exclusively used to signify a clergyman who is assistant to a rector or vicar, by whom he is employed and paid; and a clerk in deacon's orders is competent to be licensed by a bishop to the office of such assistant curate. The consequence of the abuse of the term "curate" was that the title of "perpetual curate" fell into desuetude in the Anglican Church, and an act of parliament (1868) was passed to authorize perpetual curates to style themselves vicars (see VICAR). The term is in use in the Roman Catholic Church in Ireland to designate an assistant clergyman, and also to a certain extent in the American Episcopal Church, though "assistant minister" is usually preferred.

CURATOR (Lat. for "one who takes care," curare, to take care of), in Roman law the "caretaker" or guardian of a spendthrift (prodigus) or of a person of unsound mind (furiusus), and, more particularly, one who takes charge of the estate of an adolescens, i.e. of a person sui juris, above the age of a pupillus, fourteen or twelve years, according to sex, and below the full age of twenty-five. Such persons were known as "minors,"
CURCI—CURETES

CURÉLY, JEAN NICOLAS (1774-1827), French cavalry leader, was the son of a poor peasant of Lorraine. Joining, in 1793, a regiment of hussars, he served with great distinction as private and as sous-officier in the Rhine campaigns from 1794 to 1800. He was, however, still a non-commissioned officer of twelve years' service, when at Afflenz (12th of November 1805) he attacked and defeated, with twenty-five men, a whole regiment of Austrian cavalry. This brilliant feat of arms won him the grade of sous-lieutenant, and the reputation of being one of the men of the future. The next two campaigns of the Grande Armée gained him two more promotions, and as a captain of hussars he performed, in the campaign of Wagram, a feat of even greater daring than the affair of Afflenz. Entrusted with despatches for the viceroy of Italy, Curély, with forty troopers, made his way through the Austrian lines, reconnoitred everywhere, even in the very headquarters-camp of the archduke John, and finally accomplished his mission in safety. This exploit, only to be compared to the famous raids of the American Civil War, and almost unparalleled in European war, gained him the grade of chef d'escadrons, in which for some years he served in the Peninsular War. Under Gouvion St Cyr he took part in the Russian War of 1812, and in 1813 was promoted colonel. In 1815 he was given the command of a brigade of hussars and commanded a brigade of "improvised" cavalry, and succeeded in infusing into this unpromising material some of his own daring spirit. His regiments distinguished themselves in several combats, especially at the battle of Arcis-sur-Aube. The Restoration government looked with suspicion on the most dashing cavalry leader of the younger generation, and in 1815 Curély, who during the Hundred Days had rallied to his old leader, was placed on the retired list. Withdrawing to the little estate of Saulcy (near Thiaucourt), which was his sole property, he lived in mournful retirement, which was saddened still further when in 1824 he was suddenly deprived of his rank. This last blow hastened his death. Curély, had he arrived at high command earlier, would have been ranked with Lasalle and Montbrun, but his career, later than theirs in beginning, was ended by the fall of Napoleon. His devoted friend, De Brack, in his celebrated work Light Cavalry Outposts, considers Curély incomparable as a leader of light cavalry, and the portrait of Curély to be found in its pages is justly ranked as one of the masterpieces of military literature. The general himself left but a modest manuscript, which was left for a subsequent generation to publish.

See also Thomas, Le Général Curély: itinéraires d'un Cavalier léger, 1793-1815 (Paris, 1887).

CURES, a Sabine town between the left bank of the Tiber and the Via Salaria, about 26 m. from Rome. According to the legend, it was from Cures that Titus Tatius led to the Quirinal the Sabine settlers, from whom, after their union with the settlers on the Palatine, the whole Roman people took the name Quirites. It was also renowned as the birthplace of Numa, and its importance among the Sabines at an early period is indicated by the fact that its territory is often called simply ager Sabinus. At the beginning of the imperial period it is spoken of as an unimportant place, but seems to have risen to greater prosperity in the 2nd century. It appears as the seat of a bishop in the 4th century, but seems to have been destroyed by the Lombards in A.D. 589. The site consists of a hill with two summits, round which runs the Fosso Corese: the western summit was occupied by the necropolis, the eastern by the citadel, and the latter greatly enhanced in Commercial times. A temple, the forum, the baths, &c., were excavated in 1874-1877. See T. Ashby in Papers of the British School at Rome, iii. 34. (T. As.)

CURETES (Gr. Κυρῆται and Kourēteis). (1) A legendary people mentioned by Homer (H. ix. 529 ff.) as taking part in the quarrel over the Calydonian boar. They were identified in antiquity as either Aetolians or Acarnanians (Strabo 462, 26), and were also represented by a stock in Chalcis in Euboea. (2) In mythology (unconnected with the above), the attendants of Rhea. The story went that they saved the infant Zeus from his father Cronus in Crete by surrounding his cradle and with

i.e. minores virgini quinque annis. While the tutor, the guardian of the pupillus, was said to be appointed for the care of the person, the curator took charge of the property. The term survives in Scots law for the guardian of one in the second stage of minority, i.e. below twenty-one, and above fourteen, if a male, and twelve, if a female. Under the Roman empire the title of curator was given to several officials who were in charge of departments of public administration, such as the curatores annonae, of the public supplies of corn and oil, or the curatores regionum, who were responsible for order in the fourteen regiones or districts into which the city of Rome was divided, and who protected the citizen from exaction in the collection of taxes; the curatores aquarum had the charge of the aqueducts. Many of these curatoreships were instituted by Augustus. In modern usage "curator" is applied chiefly to the keeper of a museum, art collection, public gallery, &c., but in many universities to an official or member of a board having a general control over the university, or with the power of electing to professorships. In the university of Oxford "curators" are nominated to administer certain departments, such as the University Chest.

CURCI, CARLO MARIA (1576-1601), Italian theologian, was born at Naples. He devoted himself to the study of the humanities and for some time was attached to educational work and the care of the poor and prisoners. He became one of the first editors of the Jesuit organ, the Cività Catalica; but then came under the influence of Gioberti, Rosmini and other advocates for reform. He wrote a preface to Gioberti's Primo (1843), but disserted from his Prolegomena. After the events of 1870, Curci, at Florence, delivered a course on Christian philosophy; and in 1874 began to publish several Scriptural works. In his edition of the New Testament (1879-1886) he makes some severe remarks on the neglect of the study of Scripture amongst the Italian clergy. In the meantime he began to attack the political action of the Vatican, and in his Ti Moderno Dissidio tra la Chiesa e l'Italia (1878) he advocated an understanding between the church and state. This was followed by La Nuova Italia ed i Vecchi Zelanti (1881), another attack on the Vatican policy; and by his Vaticano Regio (1883), in which he accuses the Vatican of trafficking in holy things and declares that the taint of worldliness came from the false principles accepted by the Curia. His former work at Naples drew him also in the direction of Christianity. He was condemned at Rome, and in a letter to The Times (10th of September 1884) declares that it was on account of his disobedience to the decrees of the Roman Congregation: "I am a dutiful son of the Church who hesitates to obey an order of his mother because he does not see clear enough the maternal authority in it." He was cast out of the Society of Jesus and suspended, and during this time Cardinal Manning put his purse at Curci's disposal. Finally he accepted the decrees against him and retracted "all that he said contrary to the faith, morals and discipline of the Church." He passed the remainder of his life in retirement at Florence, and, a few months before his death, was readmitted to the Jesuit Society. He died on the 8th of June 1891. (E. Tn.)

CUREL, FRANÇOIS, VICOMTE DE (1854- ), French dramatist, was born at Metz on the 10th of June 1854. He was educated at the École Centrale as a civil engineer, the family wealth being derived from smelting works. He began his literary career with two novels, L'Étoile des fruits sec (1885) and Le Souveult du grand dieu (1889). In 1892 three pieces were accepted by the Théâtre Libre. The list of his plays includes L'Envers d'une solitude (1895); Les Fossiles (1892), a picture of the prejudices of the provincial nobility; L'Invitée (1893), the story of a mother who returns to her children after twenty years' separation; L'Amour brodé (1893), which was withdrawn by the author from the Théâtre Français after the second representation; La Figure (1866); Le Repas du lion (1898), dealing with the relations between capital and labour; La Fille sauvage (1902), the history of the development of the religious idea; La Nouvelle Idaho (1899), dealing with the worship of science; and Le Coup d'âile (1906).

See also Contemporary Review for August 1903.
clashing of sword and shield preventing his cries from being heard, and thus became the body-guard of the god and the first priests of Zeus and Rhea. In historic times the cult of the Curetes was widely known in Greece in connexion with that of Rhea (g.e.). Its ceremonies consisted principally in the performance of the Pyrrhic dance to the accompaniment of hymns and flute music, by the priests, who represented and thus commemorated the original act of the Curetes themselves. The dance was originally distinguished from that of the Corybantes by its comparative moderation, and took on the full character of the latter only after the cult of the Great Mother, Cybele, to which it belonged, spread to Greek soil. The origin of the dance may have lain in the supposed efficacy of noise in averting evil.

The Curetes are represented in art with shield and sword performing the sacred dance about the infant Zeus, sometimes in the presence of a female figure which may be Rhea. Their number in art is usually two or three, but in literature is sometimes as high as ten. Of their names the following have survived: Kures, Kres, Biensos, Eleuther, Itanos, Lanabados, Panamoros, Palaxos; but no complete list of names is possible because of their confusion with the names of Corybantes and other like deities. Their origin is variously related: they were born, sprung of the rain, sons of Zeus and Hera, sons of Apollo and Danae, sons of Rhea, of the Dauctyli, contemporary with the Titans (Diod. Sic. v. 66). Rationalism made them the mortal sons of a semi-Zeus, or originators of the Pyrrhic dance, inventors of weapons, fosterers of agriculture, regulators of social life, &c. A plausible theory is that of Georg Kaibel (Göttinger Nachriclten, 1901, pp. 512-514), who sees in them, together with the Corybantes, Cabeiri, Dauctyli, Telchines, Titans, &c., only the same beings under different names at different times and in different places. Kaibel holds that they all had a phallic significance, having once been great primitive deities of procreation, and that having fallen to an indistinct, subordinate position in the course of the development and formalization of Greek religion, they survive in historic times only as half divine, half demonic beings, worshipped in connexion with the various forms of the great nature goddess. The resemblances, especially between Rhea and her Curetes and the Great Mother and her Corybantes (g.e.), were so striking that their origins were inextricably confused even in the minds of the ancients: e.g. Demetrius of Scæpsis (Strabo 469, 12) derives the Curetes and Rhea from the cult of the Great Mother in Asia, while Virgil (Aen. iii. 111) looks upon the latter and the Corybantes as derivations from the former. The worship of both was akin in nature to that of the Dauctyli, the Cabeiri, and even of Dionysus, the special visible bond being the orgiastic character of their rites.

Consult Immisch in Roscher's Lexicon, s. v. "Kureten." (G. Str.)

CURETON, WILLIAM (1808-1854), English Orientalist, was born at Westbury, in Shropshire. After being educated at the free grammar school of Newport, and at Christ Church, Oxford, he took orders in 1832, became chaplain of Christ Church, sub-librarian of the Bodleian, and, in 1837, assistant keeper of MSS. in the Bodleian Museum. He was afterwards appointed select preacher to the university of Oxford, chaplain in ordinary to the queen, rector of St Margaret's, Westminster, and canon of Westminster. He was elected a fellow of the Royal Society and a trustee of the British Museum, and was also honoured by several continental societies. He died on the 17th of June 1864.

Cureton's most remarkable work was the edition with notes and an English translation of the Epistles of Ignatius to Polycarp, the Ephesians, Smyrna, Tralles, and Smyrna, the latter being found in the monastery of St Mary Deipara in the desert of Nitria near Cairo. He held that the MS. he used gave the truest text, that all other texts were inaccurate, and that the epistles contained in the MS. were the only genuine epistles of Ignatius that we possess—a view which is now generally adopted. It was supported by F. C. Bocler, E. Burton, F. C. Bocler, and several German scholars, and is now generally abandoned (see Ignatius). Cureton supported his view by his Vindiciae Ignatianæ and his Corpus Ignatianum—a Complete Collection of the Ignatian Epistles, genuine, interpolated and spurious. He also edited a partial Syriac text of the Festal Letters of St Athanasius, which was translated into English by Henry Burgess (1854), and published in the Library of Fathers of the Holy Catholic Church; Remains of a very Ancient Recension of the Four Gospels in Syriac, hitherto unknown in Europe; Syliclegium Syriacum, containing Remains of Bardecan, Meldion, Ambrose, Mara Bar Saripon; The Third Part of the Ecclesiastical History of John, which was translated by Payne Smith; Fragments of the Illiad of Homer from an Ancient Syriac Dialect; an Arabic work known as the Thirty-first Chapter of the Book entitled The Lamp that guides Salvation, written by a Christian of Tekrit; The Book of Religious and Philosophical Sects, by Muhammad al Sharastani; a Commentary on the Book of Lamentations; the Salisbury Tanchum; and the Pillar of the Creed of the Sunnis. Cureton also published several sermons, among which was one entitled The Rule of the Trinity not Speculative but Practical. After his death Dr W. W. Warburton, editor of the ancient Syriac documents relative to the earliest Establishment of Christianity in Edessa and the neighbouring Countries, from the Year of our Lord's Ascension to the beginning of the Fourth Century, discovered, edited and annotated by the late W. Cureton.

CURETUS, a tribe of South American Indians, inhabiting the country between the rivers of Japua and Uaupés, north-western Brazil. They are short but sturdy, wear their hair long, and live in clusters of their bodies. Their houses are circular, with walls of thatch and a high conical roof. They are a peaceable people, living in small villages, each of which is governed by a mayor. They also have some knowledge of the use of iron, and are acquainted with the art of weaving. Their religion is polytheistic, and they worship a number of gods, among whom is a great god, who is supposed to have created the world.

CURFEW, CURFEET or COUVERE-FEU, a signal, as by tolling a bell, to warn the inhabitants of a town to extinguish their fires or cover them up (hence the name) and retire to rest. This was a common practice throughout Europe during the middle ages, especially in cities taken in war. In the Latin of those times it was termed igniegium or pyriegium. In medieval Venice it was a regulation from which only the Barbers' Quarter was exempt, doubtless because they were also surgeons and their services might be needed during the night. The curfew originated in the fear of fire when most cities were built of timber. That it was a most useful and practical measure is obvious when it is remembered that the household fire was usually made in a hole in the middle of the floor, under an opening in the roof through which the smoke escaped. The custom is commonly said to have been introduced into England by William the Conqueror, who ordained, under severe penalties, that at the ringing of the curfew-bell at eight o'clock the evening all lights and fires should be extinguished. But as there is good reason to believe that the curfew-bell was rung each night at Carfax, Oxford (see Peshall, Hist. of Oxford), in the reign of Alfred the Great, it would seem that all William did was to enforce more strictly an existing regulation. The absolute prohibition of lights after the ringing of the curfew-bell was abolished by Henry I. in 1100. The practice of tolling a bell at a fixed hour in the evening, still extant in many places, is a survival of the ancient curfew. The common hour was at first seven, and it was gradually advanced to eight, and in some places to nine o'clock. In Scotland ten was not an unusual hour. In early Roman times curfew may possibly have served a political purpose by obliging people to keep within doors, thus preventing treasonable nocturnal assemblies, and generally assisting in the preservation of law and order. The ringing of the "prayer-bell," as it is called, which is still practised in some Protestant countries, originated in that of the curfew-bell. In 1845 the curfew was still rung at Hastings, Sussex, from the bell at St Mary's Church on Ascension Day, and this was the custom too at Wrexham, N. Wales.

CURIA, in ancient Rome, a section of the Roman people, according to an ancient division traditionally ascribed to Romulus. He is said to have divided the people into three tribes, and to have subdivided each of these into ten curiae, each of which contained a number of families (gentes). It is more probable that the curiae were not purely artificial creations, but represent natural associations of family, artificially regulated and distributed to serve a political purpose. The local names of curiae which have come down to us suggest a local origin for the groups; but as membership was hereditary, the local tie doubtless grew weak with successive generations. Each curia was organized as a political and religious unit. As a political corporation it had no recognized activities beyond the command of a vote in the Comitia Curia (see Comitia), a vote whose nature was determined by a majority in the votes of the individual members.
CURIA REGIS—CURIA ROMANA

639

(curiales). But as a religious unit the curia had more individual activity. There were, it is true, ceremonies (sacra) performed by all the curiae to Juno Curitis in which each curia offered its part in a collective rite of the whole body; but curia had also its peculiar sacra and its own special place of worship. The religious affairs of each were conducted by a priest called curarius assisted by a flamen curialis. The thirty curiae must always have comprised the whole Roman people; for citizenship depended on membership of a gens (gentilis) and every member of a gens was ipso facto attached to a curia. They therefore included plebeians as well as patricians (q.v.) from the date at which plebeians were recognized as free members of the body politic. But, just as enjoyment of the full rights of gentilis was only very gradually granted to plebeians, so it is probable that a plebian did not, when admitted through a gens into a curia, immediately exercise all the rights of a curiatus. It is unlikely, for instance, that plebeians voted in the Comitia Curizata at the early date implied by the authorities; but it is probable that they acquired the right early in the republican period, and certain that they enjoyed it in Cicero's time. A plebian was for the first time elected curio maximus in 209 B.C. The curia ceased to have any importance as a political organization some time before the close of the republican period. But its religious importance survived during the principate; for the two festivals of the Fornacalia and the Fordicidia were celebrated by the curiae

The term curia seems often to have been applied to the common shrine of the curiales, and thus to other places of assembly. Hence the ancient senate house at Rome was known as the Curia Hostilia. The curia was also adopted as a state division in a large number of municipal towns; and the term was often applied to the senate in municipal towns (see Decurio), probably from the name of the old senate house at Rome.

Gilbert, Geschichte und Topographie der Stadt Rom (Leipzig, 1883); for municipal curiae, Mommsen, in Ephemera epigraphica, ii. p. 125; Schmidt, in Rheinisches Museum, xlvi. (1890) p. 500 ff. for the Roman curia in general see also Boeckstael, Romai Assemblies (1809).

In medieval Latin the word curia was used in the general sense of “court.” It was thus used of “the court,” meaning the royal household (aula); of “courts” in the sense of solemn assemblies of the great nobles summoned by the king (curiae solennes, &c.); of courts of law generally, whether developed out of the imperial or royal curia (see Curia Regis) or not (e.g. curia baronis, Court baron, curia christiansitatis, Court Christian). Sometimes curia means jurisdiction, or the territory over which jurisdiction is exercised; whence possibly its use, instead of cortis, for an enclosed space, the court-yard of a house, or for the house itself (cf. the English “court,” e.g. Hampton Court, and the Ger. Hof). The word curia is now only used of the court of Rome, as a convenient term to express the sum of the organs that make up the papal government (see Curia Romana).

See Du Cange, Gloss. med. et inf. Lat. (1883), s.v. “Curia.”

CURIA REGIS, or AULA REGIS, a term used in England from the time of the Norman Conquest to about the end of the 13th century to describe a council and a court of justice, the composition and functions of which varied considerably from time to time. Meaning in general the “king’s court,” it is difficult to define the curia regis with precision, but it is important and interesting because it is the germ from which the higher courts of law, the privy council and the cabinet, have sprung. It was, at first the general council of the king, or the commune concilium, i.e. the feudal assembly of the tenants-in-chief; but it assumed a more definite character during the reign of Henry I, when its members, fewer in number, were the officials of the royal household and other friends and attendants of the king. It was thus practically a committee of the larger council, and assisted the king in his judicial work, its authority being as undefined as his own. About the same time the curia under Hook financial duties, and in this way was the parent of the court of exchequer (curia regis ad soccariam). The members were called “justices,” and in the king’s absence the chief justice presided over the court. A further step was taken by Henry II. In 1118 he appointed five members of the curia to form a special court of justice, and these justices, unlike the other members of the curia, were not to follow the king’s court from place to place, but were to remain in one place. Thus the court of king’s bench (curia regis de bono) was founded, and the foundation of the court of common pleas was provided for in one of the articles of Magna Carta. The court of chancery is also an offshoot of the curia regis. About the time of Edward I, the executive and advising duties of the curia regis were discharged by the king’s secret council, the later privy council, which is thus connected with the curia regis, and from the privy council has sprung the cabinet.

In his work Tractatus de legibus Angliae, Ranulf de Glanvill treats of the procedure of the curia regis as a court of law. See W. Stubbs, Constitutional History, vol. i. (Oxford, 1883); R. Giesey, Englische Verfassungsgeschichte, English translation by P. A. Ashworth (London, 1894); A. V. Dicey, The Privy Council (London, 1887); and A. W. H. *.)

CURIA ROMANA, the name given to the whole body of administrative and judicial institutions, by means of which the pope carries on the general government of the Church; the name is also applied by an extension of meaning to the persons who form part of it, and sometimes to the Holy See itself. Rome is almost the only place where the word curia has preserved its ancient form; elsewhere it has been almost always replaced by the word court (cour, corté), which is etymologically the same. Even at Rome, however, the expression “papal court” (corte romana) has acquired by usage a sense different from that of the word curia; as in the case of royal courts it denotes the whole body of dignitaries and officials who surround and attend on the pope; the pope, however, has two establishments: the civil establishment, in which he is surrounded by what is termed his “family” (familia); and the religious establishment, the members of which form his “chapel” (capella). The word curia is more particularly reserved to the tribunals and departments which actually deal with the general business of the Church.

I. In order to understand the organization of the various constituent parts of the Roman Curia, we must remember that the modern principle of the separation of powers is inapplicable to the Curia. Each of its departments is limited solely by the extent of the powers delegated to it and the nature of the business entrusted to it; but each of them may have a share at the same time in the legislative, judicial and administrative power. Similarly, the necessity for referring matters to the pope in person, for his approval or ratification of the decisions arrived at, varies greatly according to the department and the nature of the business. But on the whole, all sections of the Curia hold their powers direct from the pope, and exercise them in his name. Each of them, then, has supreme authority within its own sphere, while the official responsibility belongs to the pope, just as in all governments it is the government that is responsible for the acts of its departments. Of these official acts, however, it is possible to distinguish two categories: those emanating directly from the heads of departments are generally called Acts of the Holy See (and in this sense the Holy See is equivalent to the Curia); those which emanate direct from the pope are called Pontifical Acts. The latter are actually the Apostolic Letters, i.e. those documents in which the pope speaks in his own name (bulls, briefs, encyclicals, &c.) even when he does not sign them, as we shall see. The Apostolic Letters have never been ex cathedra documents, and may have the privilege of infallibility. There are also certain differences between the two sorts of documents with regard to their penal consequences. But in all cases the disciplinary authority is evidently the same; we need only note that acts concerning individuals
do not claim the force of general law; the legal decisions serve at most to settle matters of jurisprudence, like the judgments of all sovereign courts.

The constituent parts of the Roman Curia fall essentially into two classes: (1) the tribunals and offices, which for centuries served for the transaction of business and which continue their activity; (2) the permanent commissions of cardinals, known by the name of the Roman Congregations. These, though more recent, have taken precedence of the former, the work of which they have, moreover, greatly relieved; they are indeed composed of the highest dignitaries of the church, the cardinals (q.v.), and are, as it were, subdivisions of the consistory (q.v.), a council in which the whole of the Sacred College takes part.

II. The Roman Congregations.—The constitution of all of these is the same; a council varying in numbers, the members of which are cardinals, who alone take part in the deliberations. One of the cardinals acts as president, or prefect, as he is called; the congregation is assisted by a secretary and a certain number of inferior officials, for secretarial and office work. They have also consultors, whose duty it is to study the subjects for consideration. Their deliberations are secret and are based on prepared documents bearing on the case, written, or more often printed, which are distributed to all the cardinals about ten days in advance. The deliberations follow a simplified procedure, which is founded on one method and are given in the shortest possible form, in answer to carefully formulated questions or dubia. The cardinal prefect, aided by the secretariat, deals with the ordinary business, only important matters being submitted for the consideration of the general meeting. To have the force of law the acts of the congregations must be signed by the cardinal prefect and secretary, and sealed with his seal. Practically the only exception is in the cases of the Holy Office, and of the Consistorial Congregation of which the pope himself is prefect; the acts of the first are signed by the "notary," and the acts of the second by the assessor.

Many pass over those temporary congregations of cardinals known also as "special," the authority and existence of which extend only to the consideration of one particular question; and also those which had as their object various aspects of the temporal administration of the papal states, which have ceased to exist since 1870. We deal here only with the permanent ecclesiastical congregations, the real machinery of the papal administration. Some of them go quite far back into the 16th century; but it was Sixtus V. who was their great organizer; by his bull Immensa of the 22nd of January 1587, he apportioned all the business of the Church (including that of the papal states) among fifteen Congregations of cardinals, some of which were already in existence, but most of which were established by him; and these commissions, or those of them at least which are concerned with spiritual matters, are still working. A few others have been added by his successors. Pius X., by the constitution Sapienti Consilio of the 29th of June 1908, proceeded to a general reorganization of the Roman Curia: Congregations, tribunals and offices. In this constitution he declared that the competency of these various organs was not always clear, and that their functions were badly arranged; that certain of them had only a small amount of business to deal with, while others were overworked; that strictly judicial affairs, with which the Congregations had not to deal originally, had developed to an excessive extent, while the tribunals, the Rota and the Signatura, had nothing to do. He consequently withdrew all judicial affairs from the Congregations, and handed them over to the two tribunals, now revived, of the Rota and the papal Signatura; all affairs concerning the discipline of the sacraments were entrusted to a new Congregation of that name; the competency of the remaining Congregations was modified, according to the nature of the affairs with which they deal, and certain of them were amalgamated with others; general rules were laid down for the expedition of business and regarding personnel; in short, the work of Sixtus V. was repeated and adapted to later conditions. We will now give the nomenclature of the Roman Congregations, as they were until 1908, and mentioning the modifications made by Pius X.

1. The Holy Inquisition, Roman and universal, or Holy Office (Sacra Congregatio Romanae et universalis Inquisitionis seu Sancti Officii), the first of the Congregations, hence called the supreme. It is composed of twelve cardinals, assisted by a certain number of officials: the assessor, who practically fulfils the functions of the secretary, the comissary general, some consultors and the qualifiers, whose duty it is to determine the degree of theological condemnation deserved by erroneous doctrinal propositions (haeretica, erronea, temeraria, &c.). The presidency is reserved to the pope, and the cardinal of longest standing takes the title of secretary. This Congregation, established in 1542 by Paul III., constitutes the tribunal of the Inquisition (q.v.), of which the origins are much older, since it was instituted in the 13th century against the Albigenses. It deals with all questions of doctrine and with the repression of heresy, together with those crimes which are more or less of the character of heresy. Its procedure is subject to the strictest secrecy. Pius X. attached to it all matters concerning indulgences; on the other hand, he transferred to the Congregation of the Council matters concerning the precepts of the Church such as fasting, abstinence and festivals. The choosing of bishops, which had in recent times been entrusted to the Holy Office, was given to the Consistorial Congregation, and dispensations from religious vows to the Congregation of the Religious Orders. The Holy Office continues, however, to deal with mixed marriages and marriages with infidels.

2. The Consistorial Congregation (Sacra Congregatio Consistorialis), established by Sixtus V., has as its object the preparation of business to be dealt with and decided in secret consistory (q.v.); notably promotions to cathedral churches and consistorial benefices, the erection of dioceses, &c. To this congregation is also subject the administration of the common property of the college of cardinals. Pius X. restored this Congregation to a position of great importance; in the first place he gave it the effective control of all matters concerning the erection of dioceses and chapters and the appointment of bishops, except in the case of countries subject to the Propaganda, and save that for countries outside Italy it has to act upon information furnished by the papal secretary of state. He further entrusted to this Congregation everything relating to the supervision of bishops and of the condition of the dioceses, and business connected with the seminaries. It has also the duty of deciding disputes as to the competency of the other Congregations. The pope continues to be its prefect, and the cardinal secretary of the Holy Office and the secretary of state are ex officio members of it; the cardinal who occupies the highest rank in it, with the title of secretary, is chosen by the pope; he is assisted by a prelate with the title of assessor, who is ex officio secretary of the Sacred College. The assessor of the Holy Office and the secretary for extraordinary ecclesiastical affairs are ex officio consultors.

3. The Pontifical Commission for the reunion of the dissident Churches, established by Leo XIII. in 1885 after his constitution Orientale. The pope reserved the presidency for himself; its activity is now nominal. It was attached by Pius X. to the Congregation of the Propaganda.

4. The Congregation of the Apostolic Visitation (Sacra Congregatio Visitationis apostolicae). The Visitations is the personal inspection of institutions, churches, religious establishments and their personnel, to correct abuses and enforce the observation of rules. Through this Congregation the pope, as bishop of Rome, made the inspection of his diocese; it is for this reason that he was president of this commission, the most important member of which was the cardinal vicar. He takes the place of the pope in the administration of the diocese of Rome; he has his own offices and diocesan assistants as in other bishoprics. The Congregation of the Visitations was suppressed by Pius X. as a separate Congregation,
and was reduced to a mere commission which is attached, as before, to the Vicariate.

(5) The Congregation on the discipline of the sacraments (Sacra Congregatio de Disciplina Sacramentorum), established by Pius X, thus comes to occupy the third rank. With the reservation of those questions, especially of a dogmatic character, which belong to the Holy Office, and of purely ritual questions, which come under the Congregation of Rites, this Congregation brings under one authority all disciplinary questions concerning the sacraments, which were formerly distributed among several Congregations and offices. It deals with dispensations for marriages, ordinations, &c., concessions with regard to the mass, the communion, &c.

(6) The Congregation of the Bishops and Regulars, of which the full official title was, Congregation for the Affairs and Consultations of the Bishops and Regulars (Sacra Congregatio super negotii Episcoporum et Regularium; now Sacra Congregatio Congregarum religiousorum sodalium praepositorum).

It is the result of the fusion of two previous commissions; that for the affairs of bishops, established by Gregory XIII., and that for the affairs of the regular clergy, founded by Sixtus V. in 1587. This Congregation was very much occupied, being empowered to deal with all disciplinary matters concerning both the secular and regular clergy, whether in the form of consultations or of contentious suits; it had further the exclusive right to regulate the discipline of the religious orders and congregations bound by the simple vows, the statutes of which it examined, corrected and approved; finally it judged disputes and controversies between the secular and regular clergy.

On the 26th of May 1906, Pius X., incorporated in this Congregation two others having a similar object: that on the discipline of the regular clergy (Congregatio super Disciplina Regularium), founded by Innocent XII. in 1695, and that on the condition of the regular clergy (Congregatio super Status Regularum), established by Pius IX. in 1846. In 1908 Pius X. withdrew from this Congregation all disciplinary matters affecting the secular clergy, and limited its competency to matters concerning the religious orders, both as regards their internal affairs and their relations with the bishops.

(7) The Congregation of the Council (Sacra Congregatio Cardinalium Concilii Tridentini interpres), i.e. a number of cardinals whose duty it is to interpret the disciplinary decrees of the council of Trent, was instituted by Pius IV. in 1553, and reorganized by Sixtus V.; its mission is to promote the observation of these disciplinary decrees, to give authoritative interpretations of them, and to reconcile disputes arising out of them. Pius X. in 1908 entrusted to this Congregation the supervision of the general discipline of the secular clergy and the faithful laity, empowering it to deal with matters concerning the precepts of the Church, festivals, foundations, church property, benefices, provincial councils and episcopal assemblies.

Proceedings for annulling marriages, which used to be reserved to it, were transferred to the tribunal of the Rota; reports on the condition of the dioceses were henceforth to be addressed to the Consistorial Congregation, which involved the suppression of the commission which had hitherto dealt with them. The other commission, formerly charged with the revision of the decrees of provincial councils, was merged in the Congregation itself. The Congregation of Immunity (Sacra Congregatio Jurisdictionis et Immunitatis ecclesiasticae) was created by Urban VIII. (1625) to watch over the immunities of the clergy in respect of person or property, whether local or general. This, having no longer any object, was also attached to the Congregation of the Council, and is now amalgamated with it.

(8) The Congregation of the Propaganda (Sacra Congregatio de Propaganda Fide) was established by Gregory XV. in 1622, and added to by Urban VIII., who founded the celebrated College of the Propaganda for the education of missionaries, and his polyglot press for printing the liturgical books of the East. It had charge of the administration of the Catholic churches in all non-Catholic countries, for which it discharged the functions of all the Congregations, except in doctrinal and strictly legislative matters. Its sphere was very wide; it administered all non-European countries, except Latin America and the old colonies of the Catholic countries of Europe; in Europe it had also charge of the Kingdom and the Balkan States. But the constitution "Sapienti" of 1908 withdrew from the Propaganda and put under the common law of the Church most of those parts in which the episcopal hierarchy had been re-established, i.e. in Europe, the United Kingdom, Holland and Luxemburg; in America, Canada, Newfoundland and the United States. Further, even for those countries it continues to administer, the Propaganda has to submit to the various Congregations all questions affecting the Faith, marriage and rites. The missions begin by establishing apostolic prefectures under the charge of priests; the prefecture is later transformed into an apostolic vicariate, having at its head a bishop; finally, the hierarchy, i.e. the diocesan episcopate, is established in the country, with residential sees. Thus the hierarchy was re-established in England in 1850 by Pius IX., in 1878 by Leo XIII. in Scotland, in 1886 in India, in 1891 in Japan. It is also the work of the Propaganda to appoint the bishops for these countries it administers. Under the same canon law the prefect is found that section of the Propaganda which deals with matters concerning oriental rites (Congregatio specialis pro negotiis ritus Orientalis), the object of which is indicated by its name. To the former were attached two commissions, one for the approbation of those religious congregations which devote themselves to missions, which is now transferred to the Congregation of the Religious Orders; the other for the examination of the reports sent in by the bishops and vicars apostolic on their dioceses or missions. With the latter is connected the commission for the examination of the liturgical books of the East (Commissio pro corrigendis libris ecclesiae Orientalis). Finally, the popes have devoted to the missions the income arising from the Chamber of Spoils (Camera Spoliorum), i.e. that portion of the revenue from church property which cannot be bequeathed by the holders of benefices as their own property; this source of income, however, has decreased greatly.

(9) The Congregation of the Index (Congregatio indicis librorum prohibitorum), founded by St. Pius V. in 1551 and reorganized by Sixtus V., has as its object the examination and the condemnation or interdiction of bad or dangerous books which are submitted to it, or, since the constitution "Sapienti," of those which it thinks fit to examine on its own initiative (see INDEX).

(10) The Congregation of Rites (Congregatio sacrorum Rituum), founded by Sixtus V., has exclusive charge of the liturgy and liturgical books; it also deals with the proceedings in the beatification and canonization of saints. Of late years there have been added to it a Liturgical Commission, a Historico-liturgical Commission, and a Commission for church song, the functions of which are sufficiently indicated by their names.

(11) The Ceremonial Congregation (Sacra Congregatio ceremonialis), the prefect of which is the cardinal deacon, was instituted by Sixtus V.; its mission is to settle questions of precedence and etiquette, especially at the papal court; it is nowadays but little occupied.

(12) The Congregation of Indulgences and Relics (Sacra Congregatio Indulgentiarum et Sacrarum Reliquiarum), founded in 1569 by Clement IX., devoted itself to eradicating any abuses which might creep into the practice of indulgences and the cult of relics. It had also the duty of considering applications for the concession of indulgences and of interpreting the rules with regard to them. In 1904 Pius X. attached this Congregation to that of Rites, making the personnel of both the same, without suppressing it. In 1908, however, it was suppressed, as stated above, and its functions as to indulgences were transferred to the Holy Office, and those as to relics to the Congregation of Rites.

(13) The Congregation of the Fabric of St Peter's (Sacra Congregatio reverendae Fabricae S. Petri) is charged with the upkeep, repairs and temporal administration of the great basilica-
in this capacity it controls the famous manufacture of the Vatican mosaics. It also formerly enjoyed certain spiritual powers for the reduction of the obligations imposed by pious legacies and foundations, the objects of which, for want of funds or any other reason, could not be fully carried out, and for the condonation of past omission of such obligations, e.g. of priests to celebrate the foundation masses of their benefices. In 1908 these powers were taken away from it by Pius X., and transferred to the Congregation of the Council, which already exercised some of them.

(14) The Congregation of Loreto (Congregatio Lauretana) discharged the same functions for the sanctuary of that name; its temporal administration was latterly very much reduced, and in 1908 it was united by Pius X. with the Congregation of the Council.

(15) The Congregation for extraordinary ecclesiastical affairs (Sacra Congregatio super negotiis ecclesiasticis extraordinarios), established by Pius VI. at the end of the 18th century to study the difficult questions relative to France, was afterwards definitively continued by Pius VII. and there has been no lack of fresh extraordinary matters. It also dealt with the administration of the churches of Latin America, not to mention certain European countries, such as Russia, under the same conditions as the Propaganda in countries under missions. Since the constitution Sapientius, its competency has been confined to the examination, at the request of the secretary of state, of questions which are submitted to it, and especially those arising from civil laws and concordats.

(16) The Congregation of Studies (Congregatio pro Universitate studii Romani, Congregazione degli studi), founded by Sixtus V. to act as a higher council for the Roman university of La Sapienza, had ceased to have any functions when in 1824 it was re-established by Leo XII. to supervise education in Rome and the Papal States; since 1890 it has been exclusively concerned with the Catholic universities, so far as the sacred sciences are concerned. With this should be connected the commission for historical studies, instituted in 1883 by Leo XIII., at the same time as he threw the Vatican archives freely open to scholars.

III. The Tribunals and Offices.—Though it has been relieved of the functions allotted to the Congregations of cardinals, the old machinery of the ecclesiastical administration has not been abolished; and the process of centralization which has been accentuated in the course of the last few centuries, together with the facility of communication, ensured for them a fresh activity, new offices having even been added. The chief thing to be observed is that the prelates who were formerly at the head of these departments have almost all been replaced by cardinals. The following is the list of the tribunals and offices, including the changes introduced by the reorganization of the Curia by Pius X. in 1908. The tribunals are three in number: one for the forum internum, the Pentitentiary; the other two for judicial matters, in foro externo, the Rota and the papal Signature.

(1) The Penitentiary (Sacra poenitentiaria Apostolica) is the tribunal having exclusive jurisdiction in matters of conscience (in foro interno), e.g. dispensations from secret impediments and private vows, the absolution of reserved cases. These concessions are applied for anonymously. It also had, previously to the constitution Sapientius, a certain jurisdiction in foro externo, such as over matrimonial dispensations for poor people. Its concessions are absolutely gratuitous. Since the 12th century, the papal court had already had officials known as penitentiaries (poenitentiarii) for matters of conscience; the organization of the Penitentiary, after several modifications, was renewed by Benedict XIV. in 1748. At the head of it is the cardinal grand penitentiary (major poenitentiarius), assisted by the regens (it. regente) and various other functionaries and officials.

(2) The court of the Rota (Sacra Rota Romana) used to be the supreme ecclesiastical tribunal for civil affairs, and its decisions had great authority. This tribunal goes back at least as far as the 14th century, but its activity had been reduced as a result of the more expeditious and summary, and less costly, procedure of the Congregations. The constitution Rota. Sapientius restored the Rota to existence and activity; it is now once more the ecclesiastical court of appeal for both civil and criminal cases. Pius X. also made special regulations for it, by which its ancient usages are adapted to modern circumstances. The tribunal of the Rota consists of ten judges called auditors (auditori), of whom the most senior is president with the title of dean. Each judge has an auxiliary; to the tribunal are attached a promotor fiscalis, charged with the duty of securing the due application of the law, and an official charged with the defence of marriage and ecclesiastical matters.

Under the jurisdiction of the Rota, in addition to cases of first instance submitted to it by the pope, are such judgments of episcopal courts as are strictly speaking subject to appeal; for petitions against non-judicial decisions are referred to the Congregations. Appeal is sometimes allowed from one "turn" to another; if the second sentence of the Rota confirms the first, it is definitive; if not, a third may be obtained.

(3) The supreme tribunal of the papal Signature (Signature Apostolica). There were formerly two sections: the Signature Justitiae and the Signature Gratiae; by the constitution Sapientius they were suppressed and amalgamated into one body, the Signature Apostolica, which is the exact equivalent of other modern courts of cassation. This tribunal is composed of six cardinals, one of whom is the prefect, assisted by a prelate secretary, consultors and the necessary inferior officials. It judges cases in which auditors of the Rota are concerned, such as personal objections, but especially objections (querelas) lodged against sentences of the Rota, with a view to their being annulled or revised (restitutio in integrum).

Next come the offices, now reduced to six in number.

(1) The Chancery (Cancellaria Apostolica), the department from which are sent out the papal letters, has, for a long time drawn up only those letters written in solemn form known as bulls. The bull, so called from the leaden seal (bulla), is written on thick parchment; the special writing known as Lombard, which used to be used for bulls, was abolished by Leo XIII., and the leaden seal reserved for the more important letters; on the others it has been replaced by a red ink stamp bearing both the emblems represented on the leaden seal: the two heads, face to face, of St Peter and St Paul, and the name of the reigning pope. Bulls are written in the name of the pope, who styles himself "(Pius) Episcopus servus servorum Dei; (Pius), bishop, servant of the servants of God." They were formerly dated by kalends and from the era of the Inception, which begins on the 25th of March, in the year 1500, the 24th of March in 1908, Pius X. abolished this according to the common era. It is practically only bulls of canonization which are signed by the pope and all the cardinals present in Rome; the signature of the pope is then "(Pius) Episcopus Ecclesiae catholicae," while his ordinary signature bears only his name and number, "Pius PP. X." Ordinary bulls are signed by several officials of the chancery, and a certain number only by the cardinal at its head, who until 1908 was styled vicar-general, because the chancellor used formerly to be a prelate, not a cardinal; but since the constitution Sapientius has been entitled chancellor. He is assisted by several officials, beginning with the regens of the chancery. To the chancery were attached the abovatoribus de parco majori vel minori (see Abbreviators), formerly charged with the drawing up or "extension" of bulls; they were suppressed by Pius X., and their functions transferred to the Protonotarii apostolici participantes (i.e. active). Formerly, Pope Pius confined the functions of the chancery to the sending out of bulls under the leaden seal (sub plumbio), for the erection of dioceses, the provision of bishoprics and
consistorial benefices, and other affairs of importance, these bulls being sent out by order of the Consistorial Congregation.

(2) The Apostolic Dataria is the department dealing with matters of grace, e.g. the concession of privileges, nominations to benefices and dispensations in foro externo, especially monastic ones; but its functions have been greatly reduced by the reforms of Pius X.; the monastic section has been suppressed, dispensations for marriages now belonging to the Congregation for the discipline of the sacraments; the section dealing with benefices, which is the only one preserved, deals with non-consistorial benefices reserved to the Holy See; it examines the claims of the candidates, draws up and sends out the letters of collation, gives dispensations, when necessary, in matters concerning the benefices, and manages the charges (i.e. pensions to incumbents who have resigned, &c.) imposed on the benefices by the pope. It has at its head a cardinal formerly called the pro-datarius, the datarius having formerly been a prelate; and now datarius, since the reform by Pius X. The cardinal is assisted by a prelate called the sub-datarius, and other officials.

(3) The Apostolic Chamber (Reverenda Camera Apostolica) was before the abolition of the temporal power of the papacy the ministry of finance, at once treasury and exchequer, of the popes as heads of the Catholic Church as well as sovereigns of the papal states. Although it is necessarily diminished in importance, it has retained the administration of the property of the Holy See, especially during a vacancy. At its head is the cardinal camerlengo (Sanctae Romanae Ecclesiae Cardinalis Camerarius), who, as we know, exercises the external authority during the vacancy of the Holy See.

(4) Next come the papal secretaries, the first and principal of which is the secretariat of state (Secretariae status). The cardinal secretary of state is as it were the pope’s prime minister, gathering into one centre the internal administration and foreign affairs, by means of the nunciatures and delegations depending on his department. The secretary of state is the successor of what was called in the 17th century the cardinal nephew; his functions and importance have increased more and more. The secretariat of state is the department dealing with the political affairs of the Church. To it belongs the internal administration of the apostolic palaces, with the library, archives, museums, &c.

In 1906 Pius X. divided the departments of the secretariat of state into three sections, under the authority of the cardinal secretary. The first is the department of extraordinary ecclesiastical affairs, having at its head the secretary of the Congregation of the same name; the second, that of ordinary affairs, directed by a substitute, is the department dealing, among other things, with the concession of honorary distinctions, both for ecclesiastics and laymen; the third is that of the briefs, which hitherto formed a separate secretariat. It is this department which sends out, at the command of the secretary of state or the various Congregations those papal letters which are written in solemn form, brevi manu, hence the word “brief.” They are written in the pope’s name, but he only takes the less solemn style of: “Pius PP. X.” The brief is written on thin parchment, and dated by the ordinary era and the day of the month; they were formerly signed only by the cardinal secretary of briefs or his substitute, but now by the cardinal secretary of state or the head of the office, called the chancellor of Briefs (cancellarius brevium). The seal is that of the fisherman’s ring; hence the formula of conclusion, “Datum Romae, ubi annuo Piscatoris.” The “fisherman’s ring” is a red ink stamp resembling a fish, a boat casting out his nets, with the name of the reigning pope.

The reform of Pius X. maintained untouched the two offices called the secretariat of briefs to princes, and the secretariat of Latin Letters, the names of which are sufficient indication of their functions. The secretariat of memorials (Secretariae Memorialium), through which pass requests addressed to the pope for the purpose of obtaining certain favours, was formerly of great importance; it is now suppressed and the requests are addressed to the proper departments. Finally, the pope has his special secretary, his auditor, with his offices, as well as the papal almonry, the officials of which administer the papal charities.

IV. The pontifical “family” (familia papalis) forms the pope’s civil court. First come the palatine cardinals, i.e. those who, on account of their office, have the right of living in the papal palaces. These were formerly four in number: the pro-datarius (now datarius), the secretary of state, the secretary of briefs, and the secretary of the nunciatures; the two last of these were suppressed in 1898. Next come the four palatine prelates, the major-domo, the superintendent of the household and its staff, and successor of the ancient vicelatimus; the master of the chamber, who presides over the arrangement of audiences; the auditor, or private secretary; and finally the master of the sacred palace (magister sacri palatii), a kind of theological adviser, always a Dominican, whose special duty is nowadays the revision of books published at Rome. Other prelates rank with the above, but in a lower degree, notably the almoner and the various secretaries.

All ecclesiastics admitted, by virtue of their office or by a gracious concession of the pope, to form part of the “family,” are called domestic prelates, prelates of the household; this is an honorary title conferred on many priests not resident in Rome. The external service of the palace is performed by the Swiss Guard and the gendarmerie; the service of the ante-chamber by the lay and ecclesiastical chamberlains; this service has also given rise to certain honorary titles both for ecclesiastics, e.g. honorary chamberlain, and for laymen, e.g. secret chamberlain (cameriere segreto). (See CHAMBERLAIN.)

V. The pontifical “chapel” (capella) is the papal court for purposes of religious worship. In it the pope is surrounded by the cardinals according to their order; by the patriarchs, archbishops and bishops attending at the throne, and others; by the prelates of the Curia, and by all the clergy both secular and regular. Among the prelates we should mention the protonotaries, the successors of the old notaries or officials of the papal chancery in the earliest centuries; the seven protonotarii participantes were restored by Pope Pius X. to the chancery, as noted above, but they have kept important honorary privileges; this is yet another source of distinction conferred upon a great number of priests outside of Rome, the protonotaries of different classes. In a lower degree there are also the chaplains of honour. Since 1870 the great pontifical ceremonies have lost much of their splendour.

CURIÓ, a province of central Chile, lying between the provinces of Colchagua and Talca and extending from the Pacific to the Argentine frontier; area, 191,758 sq. m.; pop. (1895) 187,342. The eastern and western sections are mountainous, and are separated by a low, level central valley. The mineral resources are undeveloped, but there are abundant deposits of copper, gold and silver. Cattle, wheat and wine are the principal products, but Indian corn and fruit also are produced. On the coast are important salt-producing industries. The climate is mild and the rainfall more abundant than at the northern point of the valley, and the effects of this are to be seen in the better climate.
pasturage. Irrigation is used to a large extent. The province was created in 1865 by a division of Colchagua. The capital is Curicó, on the Mataquito river, in lat. 42° 58' S. long. 7° 10' W., 114 m. S. of Santiago by the Chilean Central railway, which crosses the province. The city stands on the great central plain, 738 ft. above sea-level, and in the midst of a comparatively well-cultivated district. It was founded in 1742 by José de Manso, and is one of the more cultured and progressive provincial towns of Chile. Pop. (1895) 12,600. Vichuquén, on a tide-water lake on the coast, is a prosperous town, the centre of the salt trade.

CURIE, PIERRE (1859-1906), French physicist, was born in Paris on the 15th of May 1859, and was educated at the Sorbonne, where he subsequently became professor of physics. Although he had previously published meritorious researches on piezoelectricity, the magnetic properties of bodies at different temperatures, and other topics, he was chiefly known for his work on radium carried out jointly with his wife, Marie Sklodowska, who was born at Warsaw on the 7th of November 1867. After the discovery of the radioactive properties of uranium by Henri Becquerel in 1896, it was noticed that some minerals of uranium, such as pitchblende, were more active than the element itself, and this circumstance suggested that such minerals contained small quantities of some unknown substance or substances possessing radioactive properties in a very high degree. Acting on this surmise M. and Mme Curie subjected a large amount of pitchblende to a laborious process of fractionation, with the result that in 1898 they announced the existence in it of two highly radioactive substances, polonium and radium. In subsequent years they did much to elucidate the remarkable properties of these two substances, one of which, polonium, came to be regarded as one of the transformation-products of the other (see Radioactivity). In 1903 they were awarded the Davy medal of the Royal Society in recognition of this work, and in the same year the Nobel prize for physics was divided between them and Henri Becquerel. Professor Curie, who was elected to the Academy of Sciences in 1905, was awarded the prize in 1903, but died of a dray and killed instantly in Paris on the 10th of April 1906.

CURIO, GAIUS SCRIBONIUS, Roman statesman and orator, son of a distinguished orator of the same name, flourished during the 1st century B.C. He was tribune of the people in 90 B.C., and afterwards served in Sulla's army in Greece against Archelaus, general of Mithradates, and as his legate in Asia, where he was commissioned to restore order in the kingdoms abandoned by Mithradates. In 76 he was consul, and as governor of Macedonia carried on war successfully against the Thracians and Dardanians, and was the first Roman general who penetrated as far as the Danube. On his return he was granted the honour of a triumph. During the discussion as to the punishment of Curio's conspirators he supported Cicero, but he spoke in favours of P. Clodius (q.v.) when the latter was being tried for the Bona Dea affair. This led to a violent attack on the part of Cicero, but it does not appear to have interfered with their friendship. Curio was a vehement opponent of Caesar, against whom he wrote a political pamphlet in the form of a dialogue. He was pontifex maximus in 45, and died in 43. His reputation as an orator was considerable, but according to Cicero he was very illiterate, and his only qualifications were brilliancy of style and the purity of his Latin. He was nicknamed Burbeulius (after an actor) from the way in which he moved his body while speaking.

Orelli, Onomasticon to Cicero; Florus iii. 4; Eutropius vi. 2; Val. Max. i. 14, 5; Quintilian, Instit., vi. 3, 76; Dio Cassius xxxvii. 16.

His son, Gaius Scribonius Curio, was first a supporter of Pompey, but after his tribuneship (50 B.C.) went over to Caesar, by whom he was said to have been bribed. But, while breaking off relations with Pompey, Curio desired to keep up the appearance of impartiality. When it was demanded that Caesar should lay down his imperial power before entering Rome, Curio proposed that Pompey should do the same, adding that, if the rivals refused to do so, they ought both to be declared public enemies. His proposal was carried by a large majority, but a report having spread that Caesar was on the way to attack Rome, the consuls called upon Pompey to undertake the command of all the troops stationed in Italy. Curio's appeal to the people to prevent the levying of an army by Pompey was disregarded; whereupon, feeling himself in danger, he fled to Ravenna to Caesar. He was commissioned by Caesar, who was still unwilling to proceed to extremities, to take a message to the senate. But Curio's reception was so hostile that he hurriedly returned during the night to Caesar. It was now obvious that civil war would break out. Curio collected troops in Umbria and Etruria for Caesar, who sent him to Sicily as praefectus in 49. After having fought with considerable success there against the Pompeians, Curio crossed over to Africa, where he was defeated and slain by Juba, king of Numidia. Curio, although a man of profligate character, possessed conspicuous ability, and was a distinguished orator. In spite of his faults, Cicero, as an old friend of his father, took a great interest in him and did his utmost to reform him. Seven of Cicero's letters (Ad. Fam. ii. 1-7) are addressed to him. There can be no doubt that Curio's behaviour in regard to the laying down of the imperium by Caesar and Pompey in great measure contributed to the outbreak of civil war. The first amphitheatre in Rome was erected by him (50), for the celebration of the funeral games in honour of his father.

Orelli, Onomasticon to Cicero; Livy, Epit. 109, 110; Caesar, Bell. Civ., ii. 23, for Curio's African campaign; Appian, Bell. Civ., ii. 26-44; Vell. Pat. ii. 48.

CURITYBA (also CORITIBA and CURITIBA), capital of the state of Paraná, Brazil, situated on an elevated plateau (2016 ft. above sea-level) 68 m. W. of its seaport Paranaguá, with which it is connected by a railway remarkable for the engineering difficulties overcome and for the beautiful scenery through which it passes. Pop. (1890) 23,694; of the municipality, 24,553. It is a large resort in the population, the Germans preponderating. The city has a temperate, healthy climate, and is surrounded by a charming campo country, which, however, is less fertile than the forested river valleys. It is the principal export.

CURLEW (Fr. Corielis or Curleis), a name given to two birds, of whose cry it is an imitation, both belonging to the group Limicola, but possessing very different habits and features.

1. The long-billed curlew, or simply curlew of most British writers, the Numenius arquata of ornithologists, is one of the largest of the family Scolopacidae, or snipes and allied forms. It is common on the shores of the United Kingdom and most parts of Europe, seeking the heaths and moors of the interior and more northern countries in the breeding-season, where it lays its four brownish-green eggs, suffused with cinnamon markings, in an artless nest on the ground. In England it has been accustomed to breed in Cornwall and in the counties of Devon, Dorset, Salop, and Derby through Yorkshire. In Yorkshire it is more numerous, and thence to the extreme north of Scotland, as well as throughout Ireland, it is, under the name of whapau, familiar to those who have occasion to traverse the wild and desolate tracts that best suit its habits. So soon as the young are able to shift for themselves, both they and their parents resort to the sea-shore or mouths of rivers, from the muddy flats of which they at low tide obtain their living, and, though almost beyond any other birds wary of approach, form an object of pursuit to numerous gunners. While leading this littoral life the food of the curlew seems to consist of almost anything edible that presents itself. It industriously probes the mud or sand in quest of the worms that lurk therein, and is also active in seeking for such crustaceans and molluscs as can be picked up on the surface, while vegetable matter as well has been found in its stomach. During its summer-sojourn on the moorlands insects and berries, when they are ripe, enter largely into its diet. In bulk the curlew is not less than a crow, but it looks larger still from its long legs, wings and neck. Its bill, from 5 to 7 in. in length, and terminating in the delicate nervous apparatus
common to all birds of its family, is especially its most remarkable feature. Its plumage above is of a drab colour, streaked and mottled with very dark brown; beneath it is white, while the flight- quills are of a brownish black.

Nearly allied to the curlew, but smaller and with a more northern range, is the whimbrel (N. phaenicpous), called in some parts jack-curlew, from its small size; May-sow, from the month in which it usually arrives; and titterel, from one of its cries. This so much resembles the former in habit and appearance that no further details need be given of it. In the countries bordering on the Mediterranean occurs a third species (N. tenuirostris). Some fifteen other species, or more, have been described, but it is probable that this number is too great. The genus Numenius is almost cosmopolitan. In North America three very easily recognized species are found—the first (N. longirostris) closely agreeing with the European curlew, but larger and with a longer bill; the second (N. hudsonicus) representing the British whimbrel; and the third (N. borealis), which has several times found its way to Britain, very much less in size—indeed the smallest of the genus. All these essentially agree with the species of the British curlew in their habitat; but it is remarkable that the curlew, so conspicuous a bird can be easily distinguished by the curious colouring of its auxiliar feathers—a feature which is also presented by the American godwits (Limosa).

2. The curlew of inlanders, or stone-curlew—called also, by some writers, from its stronghold in England, the Norfolk plover, and sometimes the thick-knee—is usually classed among the Charadridae, but it offers several remarkable differences from the more normal plovers. It is the Charadrius oedicnemus of Linnaeus, the C. scolopax of Sam. Gottl. Gmelin, and the Oedicnemus crepitans of K. J. Temminck. With much the same cry as that of the Numenii, only uttered in a far sweeter tone, it is as fully entitled to the name of curlew as the bird most commonly so called. In England it is almost solely a summer visitor, though an example will occasionally linger throughout a mild winter; and is one of the few birds whose distribution is affected by geological formation, since it is nearly limited to the chalk-country—the open spaces of which it haunts, and its numbers have of late years been sensibly diminished by their inclosure. The most barren spots in these districts, even where but a superficial coating of light sand and a thin growth of turf scarcely hide the chalk below, supply its needs; though at night (and it chiefly feeds by night) it resorts to moister and more fertile places. Its food consists of snails, coleopterous insects, and earthworms, but larger prey, as a mouse or a frog, is not rejected. Without making the slightest attempt at a nest, it lays its two eggs on a level spot, a bare fallow being often chosen. These are not very large, and in colour so closely resemble the sandy, flint strewed surface that their detection except by a practised eye is difficult. The bird, too, trusts much to its own drab colouring to elude observation, and, on being disturbed, will frequently run for a considerable distance and then squat with outstretched neck so as to become almost invisible. In such a case it may be closely approached, and its large golden eye, if it do not pass for a tuft of yellow lichen, is perhaps the first thing that strikes the searcher. As autumn advances the stone-curlew gathers in large flocks, and then is as wary as its namesake.

Towards October these take their departure, and their survivors return often with wonderful constancy, to their beloved haunts. In size this species exceeds any other European plover, and looks even still larger than it is. The bill is short, blunt, and stout; the head large, broad, and flat at the top; the wings and legs long—the latter presenting the peculiarity of a singular enlargement of the upper part of the tarsus, whence the names Oedicnemus and Thick-knee have been conferred. The toes are short and fleshy, and the hind-toe is wanting. This bird seems to have been an especial favourite with Gilbert White, in whose classical writings mention of it is often made. Its range extends to North Africa and India. Five other species of Oedicnemus from Africa have also been described as distinct. Australia possesses a very distinct species (O. grallarius), and the genus has two members in the Neotropical Region (O. bistriatus and O. superciliosus). An exaggerated form of Oedicnemus is found in Aescoc, of which two species have been described, one (A. recurvirostris) from the Indian, and the other (A. magnirostris) from the northern parts of the Australian region. (A. N.)

CURLING, THOMAS BLIZARD (1811–1888). British surgeon, was born in London in 1811. Through his uncle, Sir William Blizard, he became assistant-surgeon to the London hospital in 1833, becoming full surgeon in 1849. After filling other important posts in the College of Surgeons, he was appointed president in 1873. In 1843 he won the Johannesburg prize for his investigations on tetanus; and he became famous for his skill in treating diseases of the testes and rectum, his published works on which went through many editions. He died on the 4th of March 1888.

CURLING, a game in which the players throw large round stones upon a rink or channel of ice, towards a mark called the tee. Where the game originated is not precisely known; but it has been popular in Scotland for three centuries at least. Some writers, looking to the name and technical terms of the game, trace its invention to the Netherlands; thus “curl” may have been derived from the Ger. kurswell, a game; “tee” from the Teutonic titlegen, to point out; “bonspiel,” a district curling competition, from the Belgic bonne, a district, and spel, play; the further supposition that “rink” is merely a modification of the Saxon brink, a strong man, seems scarcely tenable. Curling is called “kutting” in some parts of Lanarkshire and Ayrshire, and very much resembles quoting on the ice, so that the name may have some connexion with the Dutch coete, a quoit; while Cornelis Killian (1528–1607) in his Teutonic Dictionary gives the term khusten as meaning a pastime in which large globes of stone like the quoit or discus are thrown upon ice. Possibly some of the Flemish merchants who settled in Scotland towards the close of the 16th century may have brought the game to the country. Unfortunately, however, for the theory that assigns to it a far-away origin, we find no early mention of it in the literature of the country, while Camden, when describing the Orkney Islands in 1607, tells us that one of them supplies “plenty of excellent stones for the game called curling”; and incidental references to it as a game played in Scotland are made by several authors during the first half of the same century.

If the game be not indigenous to Scotland it certainly owes its development to that country, and in the course of time it has come to be the national sport. It was played at first with very rude engines—random whin boulders fashioned by nature alone, or misshapen granite blocks, bored through to let in the thumb of the player, having been the primitive channel stones. In course of years the rough block was superseded by a symmetrical object usually made of whinstone or granite, beautifully rounded, brilliantly polished, and supplied with a convenient handle.

Although curling boasts a literature of its own and songs innumerable, yet it has received but the scantiest notice from such important Scottish writers as Scott and Burns, or from contemporary literature in general. In 1834 an “Amateur Curling Club of Scotland” was formed, but after a “mutual admiration amateur society came to nothing, as might be expected.” Far more businesslike were the methods of the men who set afoot the “Grand Caledonian Curling Club,” which began its existence on the 1st of November 1838, and which, under its present title of “The Royal Caledonian Curling Club,” is regarded in all parts of the world as the mother-club and legislative body, even in Canada, where, however, curling conditions differ widely from those of Scotland; devotion to the mother-club does not by any means imply submission. Starting with 28 allied clubs the Royal Club grew so rapidly that there were 500 such in 1880 and 720 in 1903. It was under the auspices of the Royal Caledonian that a body of Scottish curlers visited Canada and the United States in the winter of 1902–1903, and, while a slight margin of victory remained with the home players under their own climatic con-
ditions, the visit did much to bring together the lovers of the game on both sides of the Atlantic. The assumption of the title "Royal" in place of "Grand" was due to the visit of Queen Victoria and the prince consort to Scotland in 1842, on which occasion they were initiated into the mysteries of the game on the polished floor of the drawing-room in the Palace of Scone, and the prince consort, who was presented with a pair of curling-stones, consented to become patron of the club. On his death he was succeeded by the prince of Wales, who, as Edward VII., still continued his patronage. The Club's main duties are to further the interests of the game, to revise the laws and to arrange the important matches, especially the grand match, played annually between the Scottish clubs north of the Forth & Clyde Canal and those south of it. In the first of these matches (1847) only twelve "rinks" were played; in 1903 there were no fewer than 286. During this time the southern clubs were usually victorious. Curlers claim to be a united brotherhood within which peasant and peer are equal on the ice. By 1849 the club had increased to 300, and in 1851 the game was played on the ice. Boardhead (also house or parlour), the large circle round the tee. *Bonspiel*, a match between two clubs. *Break an egg on a stone*, touch it very slightly. *Brought*, the small circles round the tee. *Chipping*, striking a stone of which a small part can be seen. *Corner*, the name for rink. *Coney or Coney*, a bosom made of broom-twig. *Draw*, to play gently. *Drive*, to play hard. *Drug ice*, soft bad ice. *Fill the port*, to block the interval between two stones. *Gogge*, tee. *Guard*, a stone that covers and protects another. *Handing out*, to hand the rink the stones for the first player. *Hand-ups*, stop sweeping. *Hog*, a stone that stops short of the hog-score, a line drawn one-sixth of the length of the rink from the tee. *Head*, an innings, both sides delivering all their stones once. *Heart*, a shot that plays without baulking the opponent. *Hitting the bullseye*, gaining a good position by rebounding off another stone. *Inwick*, the same. *Lie shot*, the stone resting nearest the tee. *Mar*, to interfere with a stone while running. *Out-turn*, to make the stone turn. *Put-and-turn*, to keep the stone on the line, the stone is usually turned the other way. *Pit-look*, a stone that lies on the tee. *Pittycock*, the oldest form of curling-stone. *Raise*, to drive a "friendly" stone nearer the tee. *Reduction*, stone which has greatly scattered the stones on the boardhead. *Red the tee*, clear away the opponents' stones. *Rink*, the space in which the game is played; also the members of a side. *Solo*, the under part of the stone; also to deliver the stone. *Soup*, to win without allowing the opponents to score at all; a term derived from a famous team of cobblers (souters) of Lochmaben, whose opponents seldom or never scored a point. *Spiel*, a match between members of the same club. *Spend the stone*, where to throw the stone to get as near as possible to the centre of the boardhead. *Sting the stone*, the mark in the centre of the boardhead, against which it is the curler's object to lay the stone. The tee may be any kind of a mark; a small iron plate with a spike in it is often used. *Teeze*, tee. *Tramp*, to walk on the ice. *Tweezes* are iron spikes which the player stands upon to deliver the stone. *Witty*, tee.

**The Rink and Implements.**—The rink is marked out in the ice, which should be very hard and smooth, in curling language "keen and clear." To keep it swept every curler carries a broom, sometimes a mere bundle of broom-twig, more often an ordinary housemaid's broom. Good "sooping," or sweeping, is part of the curler's art, and is performed subject to strict rules and under the direction of the skip, or captain; its importance lying in the fact that the progress of a stone is retarded by the ice-dust caused by the play, the sweeping of which in front of a running stone consequently prolongs its course. Apart from the broom and the crampit, the "roarin' game," as curlers love to call it, requires no further implement than the stone, a flattened, polished disk, fitted with a handle. In weight it must not exceed 44 lb. 33 to 40 lb. being usual. It must not exceed 36 in. in circumference or be less in height than one-eighth of the circumference. The two flat sides, or soles, are so shaped that one is serviceable for keen ice and the other for ice that is soft, rough or "bought." The handle can be fitted to either side, as the case demands. The curl is a power of 4 lbs. at least, and all curling weights exceed 30 lbs. generally more. In the intense cold of Canada and the United States iron is found more serviceable than stone, and the irons weigh from 60 to 70 lb. Even these are light compared with the earlier rough boulder-stones, some of which weighed over 115 lb., although the very early ones were much lighter. The modern stone took shape at the beginning of the 19th century. The ancient stones had no handles, but notches were hewn in them for finger and thumb, and, as their weight varied from 5 to 25 lb., it is probable that they were thrown after the manner of quoits. Channel-stones, stones rounded by the action of water in a river-bed, were the favourites, while the shape was a matter of individual taste, oblong and triangular stones having been common. The soles were artificially flattened. During the next period we find the heavy boulder-stones, unshaped blocks fitted with handles and probably used at shorter distances, 70 or 80 lb. being no uncommon weight. The rounded stone, made on scientific principles, did not appear until about 1880. Even then it was of all shapes and sizes, with and without handles, and not uncommonly made of wood. The stones of to-day are named after the places in which they are quarried, Ailsa Craigs, Burnocks, Carphairn Reds and Crawfordjongs being some of the best-known varieties. The stones are quarried and never blasted, as the shock of the explosion is apt to strain or split the rock.

**The Game.**—Curling is practically bowls played on the ice, the place of the "jack" being taken by a fixed mark, as at quoits, called the tee, to which the curler aims his stone; every stone that finally lies nearer than any of the opposing stones counting a point or a "shot." As each side has four players, each playing two stones, it is possible for one side to score eight points at a "head" or "innings," but in practice it is found wiser, when a good shot has been made, to play some or all of following stones with much caution, as will prevent opposing stones disturbing the stone lying near the tee. The stones thus placed are called "guards." Strategic matters like this are decided by the skip, or captain, of the rink, who plays last, and who is an autocrat whose will is law. The "lead," or first player, is expected to play quietly up the rink, leaving his stone as close to the tee as possible, but on no account beyond it. He is followed by the "second" of the other side, who, instructed by his skip, will either try to drive away the first stone, if well placed, or put his own stone in a better position. When the skip's turn comes he is "skipped," or directed, by another player, appointed by himself, usually the third player. When all sixteen stones have been delivered the players cross over, the scores are counted, and the game proceeds from the other end of the rink. If a stone fails to cross the "hog-score" it is a "hog" and is removed from the rink, unless it has struck another stone in position. Stones that pass the back-score or touch the swept snow on either side are not scored. A cleverly imparted twist a stone may be made to curve round a corner and either drive away and ousting winner or find a favourable lie for itself. This, the equivalent of "bins" in the game of bowls, is the height of scientific play. If the situation seems desperate a very hard throw, a "thunderin' cast," may succeed in clearing away the opponents' stones from the neighbourhood of the tee. Different methods are adopted in delivering the stone, but in all of them a firm stand should be taken on the crampit, and the stone swung, either quietly, or, if the skip calls for a "thunderin' cast," vigorously; but care must be taken to avoid striking the ice with the stone so as to crack or "star" the ice. All matches are for a certain number of "heads" or of points, or for all that can be made within a certain time limit, as may be agreed.

**Abridged Rules.**—*Tees* shall be 38 yds. Apart, and with the tee as centre a circle having a radius of 7 ft. shall be drawn. In alignment with the tees, lines, to be called Central Lines, are drawn from the tees to points 4 yds. behind each tee, and at these points Foot Scores 18 in. long shall be drawn at right angles, on which, at 6 in. from Central Line, the heel of the Crampit shall be placed. All matches shall be of a certain number of heads, or shots, or by time, as agreed.
Every risk of players shall be composed of four a side. No shoes likely to break the ice may be worn.

If a player should play out of turn, the stone so played may be put off the ice; if by any of the adverse party, it may be played in any way from the centre line to the tee, and behind it, the adverse party having liberty to sweep behind the tee, and in front of any of their stones when moved by another, and till at rest. Skips to have full liberty to sweep the ice in front of the tee at any time, except when a player is being directed by his skip.

If in sweeping or otherwise, a running stone be marred by any of the party to which it belongs, or if the adverse party, it may be played in any way from the centre line to the tee, and behind it, the adverse party having liberty to sweep behind the tee, and in front of any of their stones when moved by another, and till at rest. Skips to have full liberty to sweep the ice in front of the tee at any time, except when a player is being directed by his skip.

No measuring of stones allowable before the termination of the game; or the game, or the game, or their respective parties, and may play last stone, or in that part of it they please; and, when their turn to play comes, they may name one of their party to take charge for them. If any player shall play to, taunt or interrupt another, not being of his own side, he shall be delievered next. In delivering, one shot shall be added to the score of the party so interrupted. If from any change of weather after a match has been begun, or from any other reasonable cause, one player shall desire the stone, or to change to another one, and, if the two skins cannot agree, the umpire shall end played, determine whether the rink shall be shortened, and how much or whether it shall be changed, and his decision shall be final.

See Annual of the Royal Caledonian Curling Club, Edinburgh.

CURLL, EDMUND (1675-1747). English bookseller, was born in 1675 in the west of England. His parents were in humble circumstances. After being apprenticed to an Exeter bookseller, he came to London and started business on his own account, advertising himself by a system of newspaper quarrels. His connexion with the anonymously-published Court Poems in 1716 led to the long quarrel with Pope, who took his revenge by immortalizing Curll in the Dunciad. Curll became notorious for his indecent publications, so much so that "Curlism" was regarded as a synonym for literary indecency. In 1716 and again in 1721 he had to appear at the bar of the House of Lords for publishing matter concerning its members. In 1725 he was convicted of publishing obscene books, and fined in 1728 for publishing The Nun in her Snock and De Usu Flagrorum, while his Memories of John Ker of Kersland cost him an hour in the pillory. When Curll in 1735 announced the forthcoming publication of "Mr Pepys's Literary Correspondence," his stock, at Pope's instigation, was seized. It has since been proved that the publication was really instigated by Pope, who wanted an excuse to print his letters, as he actually did (1732-1741). In his forty years of business Curll published a great variety of books, of which a very large number, fortunately, were quite free from "Curlicism." A list of his publications contains, indeed, 157 standard works. He died on the 11th of December 1747.

For Curll's relations with Pope, see the Life of Pope, by Sir Leslie Stephen in the English Men of Letters series.

CURRAGH, a level stretch of open ground in Co. Kildare, Ireland, famous for its race-course and its military camp. It has an area of upwards of 800 acres; and its soft natural sward, which has never been broken by the plough, affords excellent pasture for sheep. From the peculiarity of its herbage, the district is known in the neighbourhood as "the short grass," and the young men of Kildare are jocularly distinguished as the "boys of the short grass." The land is the property of the crown, which appoints a special officer as the ranger of the Curragh; but the right of pasturage is possessed by the landowners of the vicinity. The oldest mention of the Curragh occurs in the Liber Hymnorum (the manuscript of which probably dates from the 10th century) in connexion with St Bridget, who is said to have received a grant of the district from the king of Leinster, and is popularly credited with the honour of having turned it into a common. It is evident, however, that long before the days of the saint the downs of Kildare had afforded a great place of assembly for the people of the south of Ireland. The word cuirrech, cognate with the Lat. cursus, signifies a race-course, and chariot-races are spoken of as taking place on the Curragh as early as the 1st century A.D. The Aenach Colmain (Curragh fair), also called Aenach Life (the fair on the plain of the Lifey), is frequently mentioned in the Irish annals, and both racing and other sports were carried on at this, the principal meeting of its kind in southern Ireland, and the plain appears from time to time as the scene of hostile encounters between the kings of Meath, Leinster, and Offaly. In 1234 the earl of Pembroke was defeated here by the vicerey of Ireland, Lord Geoffrey de Monte Marisco; and in 1406 the Irish under the prior of Connell were routed by the English. In 1789 the Curragh was the great rendezvous for the volunteers, and in 1804 it saw the gathering of 30,000 United Irishmen. The camp was established at the time of the Crimean War, and is capable of accommodating 12,000 men. The races are held in April, June, September and October.

See W. M. Hennessy, in Proceedings of Royal Irish Acad., 1866.

CURRAN, JOHN PHILPOT (1750-1817), Irish politician and judge, was born on the 24th of July 1750, at Newmarket, Cork, where his father, a descendant of one of Cromwell's soldiers, was seneschal to the manor-court. He was educated at Middle- ton, through the kind help of a friend, the Rev. Nathaniel Boyse, at Trin. Coll. Dublin, and in 1773, having taken his M.A. degree, he entered the Middle Temples. He was appointed a lady who brought him a small dowry; but the marriage proved unhappy, and Mrs Curran finally eloped from her husband.

In 1775 Curran was called to the Irish bar, where he very soon obtained a practice. A young man in court excessive nervousness prevented him from even reading distinctly the few words of a legal form, and when requested by the judge, to read more clearly he became so agitated as to be totally unable to proceed. But, his feelings once roused, all nervousness disappeared. His effective and witty attack upon a judge who had sneered at his poverty, the success with which he prosecuted a nobleman for a disgraceful assault upon a priest, the duel which he fought with one of the witnesses for this nobleman, and other similar exploits, gained him such a reputation that he was soon the most popular advocate in Ireland.

In 1783 Curran was appointed king's counsel; and in the same year he was presented to a seat in the Irish House of Commons. His conduct in connexion with this affair displays his conduct
in a most honourable light; finding that he differed radically in politics from the gentleman from whom he had received his seat, he expended £1500 in buying another to replace that which he occupied. In his parliamentary career Curran was throughout sincere and consistent. He spoke vigorously on behalf of Catholic interests, a cause, and strenuously attacked the ministerial bribery which prevailed. His declarations against the government party led him into two duels—the first with John Fitzgibbon, then attorney-general, afterwards Lord Clare; the second with the secretary of state, Major Hobart, afterwards earl of Buckinghamshire. The Union caused him the bitterest disappointment; he even talked of leaving Ireland, either for America or for England.

Curran's fame rests most of all upon his speeches on behalf of the accused in the state trials that were so numerous between 1794 and 1803; and among them may be mentioned those in defence of Hamilton Rowan, the Rev. William Jackson, the brothers John and Henry Sheares, Peter Finnruty, Lord Edward Fitzgerald, Wolfe Tone and Owen Kirwan. Another of his most famous and characteristic speeches is that against the marquis of Headfort, who had eloped with the wife of a clergyman named Massey. On the arrest of Robert Emmet, who had formed an attachment to his daughter, Curran was himself under suspicion; but, on examination before the privy council, nothing was brought forward to implicate him, and he was set at liberty.

In 1806, on the death of Pitt and the formation of the Fox ministry, Curran received the post of master of the rolls, with a seat in the privy council, much to his disappointment, for he had desired a position of greater political influence. For eight years, however, he held this office. He then retired on a pension of £3000; and the three remaining years of his life were spent in London, where he became one of the most brilliant members of the society which included Sheridan, Erskine, Thomas Moore, and William Godwin. He died at his house in Brompton on the 14th of October 1817.

Curran's legal erudition was never profound; and though he was capable of the most ingenuous pleading, his appeal was always to the emotions of his audience. His best speeches are one fiery torrent of inventive, pathos, national feeling and wit. His diction was lofty and sonorous. He was, too, a most brilliant wit and of wonderful quickness in repartee. To his personal presence he owed nothing; for he was short, slim and boyish-looking, and his voice was thin and shrill.

See Curran and his Contemporaries, a most entertaining work, by Charles' friend of Curran's (1818), and the Life of Curran, by his son, W. H. Curran (1819), and with additions by Dr. Shelton Mackenzie, New York, 1855, both of which contain numerous samples of Curran's eloquence. See also Curran's Speeches (1806–1817), Votes of Curran, by Wm. O'Regan (1871); Letters to Rev. H. Weston (1819); T. Moore's Memoirs (1853).

CURRANT. (1) The dried seedless fruit of a variety of the grape-vine, Vitis vinifera, cultivated principally in Zante, Cephalonia and Ithaca, and near Patras, in the Morea (see Greece). Currants were brought originally from Corinthis, whence their name; in the 13th and 14th centuries they were known as raisins de Corinthe. In the Ionian Islands the currant-vine is grown on the sides of the lower hills, or in the valleys, the grape-vine occupying the higher and less open and rich ground. Gypsiferous marls, or calcareous marls containing a little gypsum, are preferred to limestone soils, as they allow of deep penetration of the roots of the vines. The most favourable situations are those where a good supply of water can be obtained for the irrigation of the plantations. This is carried on from the end of October to the close of the year, after which all that is necessary is to keep the ground moist. The vines are planted in rows 3 or 4 ft. apart. Propagation is effected by grafting on stocks of the grape-vine, or by planting out in spring the young vigorous shoots obtained at the end of the previous year from old grape-vine shoots that have been cut away below the ground. The grafts bear fruit in three years, the slips in about double that time. The vine stock for grafting is cut down to the depth of a foot below the surface of the soil; two or three perpendicular incisions are made near the bark with a chisel; and into these are inserted shoots of the last year's growth. The engrafted part then receives an application of moist marls, is wrapped in leaves and bound with rushes, and is covered with earth, two or three eyes of the shoots being left projecting above ground. In December the currant plantations are cleared of dead and weak wood. In February the branches are cut back, and pruned of median shoots, which are said to prevent the lateral ones proceeding from the same bud from bearing fruit. In order effectually to water the trees, the earth round about them is in February and March hoed up so as to leave them in a kind of basin, or is piled up against their stems. In March, when the leaves begin to show, the ground is thoroughly turned, and if requisite manured, and is then re-leveled. By the middle of April the leaves are fully out, and in June it is necessary to break back the newly-formed shoots. The fruit begins to ripen in July, and in the next month the vintage takes place. At this season rain is greatly dreaded, as it always damages and may even destroy the ripe fruit. The plantations, which are commonly much exposed, are watched by dogs and armed men. In Cephalonia the currant-grape is said to ripen at least a week earlier than in Zante. To destroy the oldum, a fungal pest that severely injures the plantations, the vines are dusted, at the time the fruit is maturing, with finely-ground brimstone. The currants when sufficiently ripe are gathered and placed on a drying ground, where they are exposed to the sun in layers half an inch thick; from time to time they are turned and swept into heaps, until they become entirely detached from stalk. They are then packed in large butts for exportation. The wine made from the currant-grape is inferior in quality, but is said to be capable of much improvement. The fresh fruit is luscious and highly flavoured, but soon cloyes the palate.

(2) The currants of British kitchen-gardens—so called from a resemblance to the foregoing—are the produce of Ribes nigra, deciduous shrubs of the natural order Ribesieaeae, indigenous to Britain, northern and central Europe, Siberia and Canada. The former species bears the black, the latter the red currant. White currants are the fruit of a cultivated variety of R. rubrum. Both red and black currants are used for making tarts and pies, jams, jellies and wine; the latter are also employed in lozenges, popularly supposed to be of value in relieving a sore throat, are occasionally preserved in spirits, and in Russia are fermented with honey to produce a strong liquor.

Currants will flourish in any fairly good soil, but to obtain large crops and fine fruit a good rich loam is desirable; with an annual cover of horse manure or cowdung, after the winter pruning, for established trees. The plants are best propagated by cuttings, which should consist of strong well-ripened young shoots taken off close to the old wood. These should be planted as soon as possible after the wood is matured in autumn about 6 in. apart. The plants are grown with the best results as bushes, but may also be trained against a wall or trellis. In the matter of pruning it must be borne in mind that red and white currants form their fruit buds on wood two to three years old, and the main shoots and side branches may therefore be cut back. Black currants on the other hand form fruit buds on the new wood of the previous year, hence the old wood should be cut away and the young left.

The black currant is subject to the attacks of a mite, Phytoptus ribis, which destroys the unopened buds. The buds, when attacked, recognized by their swollen appearance, should be picked off and burned. The attacks of the caterpillars of the gooseberry and other moths may be met by dusting the bushes with lime and soot when the plants are moist with dew or after syringing.

The following forms are recommended for cultivation:—Black: Lee's Profligate, Baldwin's or Carter's Champion and Black Nacles; Red: Cherry, Raby Castle, Red Dutch and Comet; White: White Dutch. A kind of black currant (Ribes magellanicum), bearing poor and acid fruit, is indigenous to Tierra del Fuego.

CURRICLE (Lat. curriculum, a small car), a light two-wheeled vehicle, generally for driving with two horses.
CURRIE, SIR DONALD—CURSOR

CURRIE, SIR DONALD (1825-1900), British shipowner, was born at Greenock on the 3rd of September 1825. At a very early age he was employed in the office of a shipowner in that port, but at the age of eighteen left Scotland for Liverpool, where shipping business offered more scope. By a fortunate chance he attracted the notice of the chief partner in the newly started Cunard steamship line, who found him a post in that company. In 1849 the Cunard Company started a service between Havre and Liverpool to connect with their transatlantic service. Currie was appointed Cunard agent at Havre and Paris, and secured for his firm a large share of the freight traffic between France and the United States. About 1856 he returned to Liverpool, where till 1862 he held an important position at the Cunard Company’s headquarters. In 1862 he determined to strike out for himself, and leaving the Cunard established the “Castle” line of sailing-ships between Liverpool and Calcutta. Business prospered, but in 1864 Currie found it profitable to substitute London for Liverpool as the home port of his vessels, and himself settled in London. In 1872 he came to the conclusion, after a careful study of all the circumstances, that the development of Cape Colony justified the starting of a new line of steamers between England and South Africa. The result of this decision was the founding of the successful Castle line of steamers (see under Steamship Lines), which after 1876 divided the South African mail contract with the older Union line, and was finally amalgamated with the latter under the title Union Castle line in 1900. Currie’s intimate knowledge of South African conditions and persons was on several occasions of material service to the British government. His acquaintance with Sir John Brand, the president of what was then the Orange Free State, caused him to be entrusted by the home government with the negotiations in the dispute concerning the ownership of the Kimberley diamond-fields, which were brought to a successful conclusion. He introduced the two Transvaal deputations which came to England in 1877 and 1878 to protest against annexation, and though his suggestions for a settlement were disregarded by the government of the day, the terms on which the Transvaal was subsequently restored to the Boers agreed, in essentials, with those he had advised. The first news of the disaster of Isandhlwana in the Zulu War was given to the home government through his agency. At that time there was no cable between England and South Africa, and the news was sent by a Castle liner to St Vincent, and telegraphed thence to Currie. At the same time by diverting his outward mail-boat then at sea from its ordinary course to St Vincent, he enabled the government to telegraph immediate instructions to that island for conveyance thence by the mail, thus saving serious delay, and preventing the annihilation of the British garrison at Escombe. The present arrangement under which the British admiralty is enabled to utilize certain fast steamers of the mercantile marine as armed cruisers in war-time was suggested and strongly urged by Currie in 1880. In the same year he was returned to parliament as Liberal member for Periborough, but, though a strong personal friend of W. E. Gladstone, he was unable to follow that statesman on his policy, and in 1886 to 1887 served as Under Secretary of State for the Home Department, and from 1887 to 1900 for West Perthshire as a Unionist. In 1881 his services in connexion with the Zulu War were rewarded with knighthood, and in 1897 he was created G.C.M.G. He died at Sidmouth on the 13th of April 1900.

CURRIE, JAMES (1756-1802), Scottish physician and editor of Burns, son of the minister of Kirkpatrick-Fleming, in Dumfriesshire, was born there on the 31st of May 1756. Attracted by the stories of prosperity in America he went in 1777 to Virginia, where he spent five hard years, much of the time ill and always in unprofitable commercial business. The outbreak of war between the Colonies and England ended any further chance of success, and sailing for home in the spring of 1787 after many delays he reached England a year later. He then proceeded to study medicine at Edinburgh, and after taking his degree at Glasgow he settled at Liverpool in 1780, where three years later he became physician to the infirmary. He died at Sidmouth on the 31st of August 1802. Among other pamphlets Currie was the author of Medical Reports on the Effects of Water, Cold and Warm, as a Remedy in Fevers and Febrile Diseases (1797), which had some influence in promoting the use of cold water affusion, and contains the first systematic record in English of clinical observations with the thermometer. But he is best known for his edition (1800), long regarded as the standard, of Robert Burns, which he undertook in behalf of the family of the poet. It contained an introductory criticism and an essay on the character and condition of the Scottish peasantry. See the Memoir by W. W. Currie, his son (1831).

CURRY. (1) (Through the O. Fr. corriceir, from Late Lat. corredore, to make ready, prepare; a later form of the French courrier, and modern French corroyer), to dress a horse by rubbing down and grooming with a comb; to dress and prepare leather already tanned. The currier pares off roughnesses and inequalities, makes the leather soft and pliable, and gives it the necessary surface and colour (see Leather). The word “currier,” though early confused in origin with “to curry,” is derived from the Late Lat. curiaris, a leather dresser, from curium, hide. The phrase “to curry favour,” to flatter or cajole, is an 16th century corruption of “to curry favel,” i.e. a chestnut horse. This older phrase is an adaptation of an Old French proverbial expression estriuier fauvel, and is paralleled in German by the similar den fahlen Hengst streichern. A chestnut or fallow horse seems to have been taken as typical of deceit and trickery, at least since the appearance of a French satirical beast romance the Roman de fauvel (1510), the hero of which is a counterpart of Reynard the Fox (q.v.).

(2) A name applied to a great variety of seasoned dishes, especially those of Indian origin. The word is derived from the Tamil kari, a sauce or relish for rice. In the East, where the staple food of the people consists of a dish of rice, wheat cakes, or some other cereal, some kind of relish is required to lend attraction to this insipid food; and that is the special office of curry. In India the following are employed as ingredients in curries: anise, coriander, cumin, mustard and poppy seeds; allspice, almonds, saffoetida, butter or ghee, cardamoms, chillies, cinnamon, cloves, cocoa-nut and cocoanut milk and oil, cream and curds, fenugreek, the tender unripe fruit of Buchanania lanzolofia, cherojonje nuts (the produce of another species, B. latifolia), garlic and onions, ginger, lime-juice, vinegar, the leaves of Bergera Koenigii (the curry-leaf tree), mace, mangoes, nutmeg, pepper, saffron, salt, tamarinds and turmeric.

The cumin and coriander seeds are generally used roasted. The various materials are cleaned, dried, ground, sifted, thoroughly mixed and bottled. In the East the spices are ground freshly every day, which gives the Indian curry its superiority in flavour over dishes prepared with the curry-powders of the European market.

CURSOR, LUCIUS PAPIRUS, Roman general, five times consul and twice dictator. In 235 he was appointed dictator to Succour Samnite War, but disagreed with Q. Fabius Maximus Rullianus, his magister equitum, and was recalled. The latter had engaged the enemy against the orders of Cursor, by whom he was condemned to death, and only the intercession of his father, the senate and the people, saved his life. Cursor treated his soldiers with such harshness that they allowed themselves to be defeated; but after he had regained their good-will by more lenient treatment and lavish promises of booty, they fought with enthusiasm and gained a complete victory. After the disaster of the Caunide Forks, Cursor to some extent wiped out the disgrace by compelling Lucchini (who had revolted) to surrender. He delivered the Roman hostages who were held in captivity in the town, recovered the standards lost at Caunide, and made 7000 of the enemy pass under the yoke. In 309, when the Samnites again rose, Cursor was appointed dictator for the second time, and gained a decisive victory at Longula, in honour of which he celebrated a magnificent triumph. Cursor’s strictness was proverbial; he was a man of immense bodily strength, while his bravery was

Hupe, "Cursor Studies and Criticisms on the Dialects of its MSS." (1888), by Dr Hupe and a glossary by Dr Max Kaluz. CURTAIN, a screen of any textile material, running by means of rings fixed to a rod or pole. Curtains are now used chiefly to cover windows and doors, but for many centuries every bed of importance was surrounded by them, and sometimes, as in France, the space thus screened off was much larger than the actual bed and was called the ruelle. The curtain is very ancient—indeed the absence of glass and ill-fitting windows long made it a necessity. Originally single curtains were used; it would appear that it was not until the 17th century that they were employed in pairs. Curtains are made in an infinite variety of materials and styles; when placed over a door they are usually called portières. In fortification the "curtain" is that part of the enceinte which lies between two bastions, towers, gates, &c.

The word comes into English through the O. Fr. cortine or courteine from the Late Lat. cortina. According to Du Cange (Glossarium, s.v. "Cortis") this is a diminutive of cortis, an enclosed space, a court. It is used in the various senses of the English "curtain." Classical Latin had also a word cortina, meaning a caldron or round kettle. It was very rarely applied to round objects generally. In the Vulgate cortina is used of the curtains of the tabernacle (Exodus xxvi). There is some difficulty in connecting the classical and the Late Latin words. The earliest use in English is, according to the New English Dictionary, for the hangings of a bed.

CURTANA (a latinized form of the A.-Fr. curtein, from Lat. curtus, shortened), the pointless sword of mercy, known also as Edward the Confessor's sword, borne at the coronation of the kings of England between the two pointed swords of temporal and spiritual justice (see REGALIA). CURTEA DE ARGESH (Rumanian, Curtea de Argeș; also written Curtea de Argeș, Curtea Argeș, Curtea Arges and Argeș), the capital of the department of Argeș, Romania, situated on the right bank of the river Argesh, where it flows through a valley of the lower Carpathians; and on the railway from Pitești to the Rothenthurm Pass. Pop. (1900) 4216. The city is one of the oldest in Rumania. According to tradition it was founded early in the 14th century by Prince Radu Negru, succeeding Câmpulung as capital of Walachia. Hence its name Curtea, "the court." It contains a few antique churches, and was created a bishops' see at the close of the 18th century.

The cathedral of Curtea de Argeș, by far the most famous building in Rumania, stands in the grounds of a monastery, 1⁄2 m. N. of the city. It resembles a very large and elaborate mausoleum, built in Byzantine style, with Moorish arabesques. In shape it is oblong, with a many-sided annex at the back. In the centre rises a dome, fronted by two smaller cupolas; while a secondary dome, broader and loftier than the central one, springs from the annex. Each summit is crowned by an inverted pear-shaped stone, bearing a triple cross, emblematic of the Trinity. The windows are mere slits; those of the tambours, or cylinders, on which the curtain was curved, and slant at an angle of 70°, as though the tambours were leaning to one side. Between the pediment and the cornice a thick corded moulding is carried round the main building. Above this comes a row of circular shields, adorned with intricate arabesques, while bands and wreaths of lilies are everywhere sculptured on the windows, balconies, tambours and cornices, adding lightness to the fabric. The whole is raised on a platform 7 ft. high, and encircled by a stone balustrade. Facing the main entrance is a small open shrine, consisting of a cornice and dome upheld by four pillars. The cathedral is faced with pale grey limestone, easily chiselled, but hardening on exposure. The interior is of brick, plastered and decorated with frescoes. Close by stands a large royal palace, Moorish in style. The archives of the cathedral were plundered by Magyars and Moslems, but several inscriptions, Greek, Slav and Ruman, are left. One tablet records that the founder was Prince Neagoe Bassarab (1512-1521); another that Prince John Radu

Beyond dispute. He was surnamed Cursor from his swiftness of foot.

Livy viii., ix.; Aurelius Victor, De viris illustribus, 37; Eutropius ii. 8. 9.

His son of the same name, also a distinguished general, completed the subjection of Samnia (272). He set up a sun-dial, the first of its kind in Rome, in the temple of Quirinus.

Livy x. 39-47; Pliny, Nat. Hist., vii. 60.

CURSOR MUNDI, an English poem in the Northern dialect dating from the 13th century. It is a religious epic of 24,000 lines "over-running" the history of the world as related in the Old and New Testaments. "Cursor o werld man agh it call, For almost it over-rennes all." The author explains in his prologue his reasons for undertaking the work. Men desire to read old romances of Alexander, Julius Caesar, Greece, Troy, Brutus and other heroes of the tabernacle, Tristram, Sweet Ysoande and others. But better than tales of love is the story of the Virgin who is man's best lover, therefore in her honour he will write this book, founded on the steadfast ground of the Holy Trinity. He writes in English for the love of English people of merry England, so that those who know no French may understand. The history is treated under seven ages. The first four include the period from the creation of the world to the successors of Solomon, the fifth deals with Mary and the birth and childhood of Jesus, the sixth with the lives of Christ and the chief apostles, and with the finding of the holy cross, and the seventh with Doomsday. Four short poems follow, more in some MSS. The bulk of the poem is written in rhyming couplets of short lines of four accents, and maintains a fair level throughout. The narrative is enlivened by many legends and much entertaining matter drawn from various sources; and the numerous transcripts of it prove that it was able to hold its own against profane romance.

The chief sources of the compilation have been identified by Dr Haensch. For the Old Testament history the author draws largely from the Historia salutis universae, of Cange, but sometimes he even transcribes directly from Wace's Établissement de la fête de la conception Notre Dame; the parables of the king and four daughters, and of the castle of Love and Grace, are taken from "Sent Robert bok" (10516), that is, from the Chasteau d'Amor of Robert Grosseteste, bishop of Lincoln; other sources are the apocryphal gospels of Matthew and Nicodemus, a southern English poem on the Assumption of Our Lady, attributed by the writer of Cursor mundi to Edmund Rich of Pontigny, the Vulgate, the Legenda aurea of Jacobus de Voragine, and the De vita et morte sanctorum of Isidore of Seville. The original of the section on the invention of the holy cross is still to seek. In its general plan the work is similar to the Livre de sapience of Herman de Valenciennes.

Of the author nothing is known. In the Cotton MS. Vespasian (A III.) the name of the owner William Cosyn is given (for particulars of this family, which is mentioned in Lincolnshire records as early as 1276, see Dr H. Hupe in the E.T.S. ed. of Cursor mundi, vol. i. p. 124*). The date of the book was placed by Dr J.-A.-H. Murray (The Dial of the Dialects of the Southern Counties of Scotland, 1873, p. 36) in the last quarter of the 13th century, and the place of writing near Durham. Dr Hupe (loc. cit. p. 186*) gives good reasons for believing that the author was a Lincolnshire man, who wrote between 1260 and 1290, although the Cotton MS. probably belongs to the late 14th century. In the Göttingen MS. there are lines (17600-17710) desiring the reader to pray for John of Lindbergh, "that this bok gart dight," and cursing anybody who shall steal it. Lindberg is probably Limer Magna, near Ulceby, in north Lincolnshire. Dr Hupe hazards an identification of the author with this John of Lindberg, who may have been a member of the Cistercian Abbey of Lindberg; but this is improbable.

Cursor mundi was edited for the Early English Text Society in 1874-1893 by Dr Richard Morris in parallel columns from four MSS.—Cotton Vespasian A II., British Museum; Fairfax MS. 14, in the Bodleian library, Oxford; MS.-theol. 107 at Göttingen; and MS. R. 38 in Trinity College, Cambridge. The edition includes a "Preface" by the editor, "An Inquiry into the Sources of the Cursor mundi."
completed the work in 1526. A third describes the repairs executed in 1681 by Prince Sherban Cantacuzino; a fourth, the restoration, in 1804, by Joseph, the first bishop. Between 1875 and 1885 the cathedral was reconstructed; and in 1886 it was re-consecrated. Its legends have inspired many Rumanian poets, among them the celebrated V. Alexandri (1821-1890). One tradition describes how Neagoe Bassarab, while in hostage in Constantinople, designed a splendid mosque for the sultan, returning to build the cathedral out of the surplus materials. Another version makes him employ one Manole or Manoli as architect. Manole, being unable to finish the walls, the prince threatened him and his assistant with death. At last Manole suggested that they should follow the ancient custom of building a living woman into the foundations; and that she who first appeared on the following morning should be the victim. The other masons warned their families, and Manole was forced to sacrifice his own wife. Thus the cathedral was built except the roof. So arrogant, however, was the Moslem that he dared to remove the scaffolding, and all, save Manole, perished of hunger. He fell to the ground, and a spring of clear water, which issued from the spot, is still called after him.

**Curtesy** (a variant of “courtesy,” q.v.), in law, the life interest which a husband has in certain events in the lands of which his wife was in her lifetime actually seised for an estate of inheritance. As to the historical origin of the custom and the meaning of the word there is considerable doubt. It has been said to be an interest peculiar to England and to Scotland, hence called the “courtesy of England” and the “courtesy of Scotland”; but this is erroneous, for it is found also in Germany and France. The *Mirrour des Justices* ascribes it to Henry I. K. E. Digby (Hist. Real Prop. chap. iii.) says that it is connected with *curia*, and has reference either to the attendance of the husband as tenant of the lands at the lord's court, or to mean simply that the husband is acknowledged tenant by the courts of England and Scotland. The requisites necessary to make tenancy by the curtesy are: (1) a legal marriage; (2) an estate in possession of which the wife must have been actually seised; (3) issue born alive and during the mother's existence, though it is immaterial whether the issue live or die, or whether it is born before or after the wife's seisin; in the case of gavelkind lands the husband has a right to curtesy, whether there is issue born or not; but the curtesy extends only to a moiety of the wife's lands and ceases if the husband marries again. The issue must have been capable of inhering as heir to the wife, e.g. if a wife were seised of lands in tail male the birth of a daughter would not entitle the husband to a tenancy by curtesy; (4) the title to the tenancy vests only on the death of the wife. The Married Women's Property Act 1882 has not affected the right of curtesy so far as relates to the wife's undisposed-of realty (Hope v. Hope, 1892, 2 Ch. 336), and the Settled Land Act 1882 has for the purposes of the Settled Land Act 1882 the estate of a tenant by curtesy is to be deemed an estate under a settlement made by the wife.

**Curtilage** (Med. Lat. *curtilgium*, from *curtille* or *curtille*, a court or yard, cf. “court”), the area of land which immediately surrounds a dwelling-house and its yard and outbuildings. In feudal times every castle with its dependent buildings was protected by a surrounding wall, and all the land within the wall was termed the curtilage; but the modern legal interpretation of the word, i.e. what area is enclosed by the curtilage, depends upon the circumstances of each individual case, such as the terms of the grant or deed which passes the property, or upon what is held to be a convenient amount of land for the occupation of the house, &c. The importance of the word in modern law depends on the fact that the curtilage marks the limit of the premises in which housebreaking can be committed.

**Curtin, Andrew Gregg** (1817-1894), American political leader, was born at Bellefonte, Centre county, Pennsylvania, on the 22nd of April 1817, the son of a native of Ireland who was a pioneer iron manufacturer in Pennsylvania. He graduated from the law department of Dickinson College in 1837, was admitted to the bar in 1839, and successfully practised his profession. Entering politics as a Whig, he was chairman of the Whig state central committee in 1854, and from 1855 to 1858 was secretary of the commonwealth. In this capacity he was also ex officio the superintendent of common schools, and rendered valuable services to his state in perfecting and expanding the free public school system, and in establishing state normal schools. Upon the organization of the Republican party he became one of its leaders in Pennsylvania, and in October 1860 was chosen governor of the state on its ticket, defeating Henry D. Foster, the candidate upon whom the Douglas and Breckinridge Democrats and the Constitutional Unionists had united, by 32,000 votes, after a spirited campaign which was watched with intense interest by the entire country as an index of the result of the ensuing presidential election. During the Civil War he was one of the closest and most constant advisers of President Lincoln, and one of the most efficient, most energetic and most patriotic of the "war governors" of the North. Pennsylvania troops were the first to reach Washington after the president's call, and from first to last the state, under Governor Curtis's guidance, furnished 300,914 officers and men to the Northern armies. One of his wisest and most praiseworthy acts was the organization of the famous "Pennsylvania Reserves," by means of which the state was always able to fill at once its required quota after each successive call. In raising funds and equipping and supplying troops the governor showed great energy and resourcefulness, and his plans and organizations for caring for the needy widows and children of Pennsylvania soldiers killed in battle, and for aiding and removing to their homes the sick and wounded were widely copied throughout the North. He was re-elected governor in 1863 and served until January 1867. He was United States minister to Russia from 1869 until 1872, when he returned to America and took part in the presidential canvass of 1872. In August 1872-1873 he was a member of the state constitutional convention. Subsequently he joined the Democratic party and was a representative in Congress from 1881 to 1887. He died at his birthplace, Bellefonte, Pennsylvania, on the 7th of October 1894.

**Curtis, George Ticknor** (1812-1894), American lawyer, legal writer and constitutional historian, was born in Watertown, Massachusetts, on the 28th of November 1812. He graduated at Harvard in 1832, was admitted to the bar in 1836, and practised in Worcester, Boston, New York and Washington, appearing before the United States Supreme Court in many important cases, including the Dred Scott case, in which he argued the constitutional question for Scott, and the legal tender cases. In Boston he was for many years a member of the United States commissioner, and in this capacity, despite the vigorous protests of the abolitionists and his own opposition to slavery, ordered the return to his owner of the famous fugitive slave, Thomas Sims, in 1852. He was the nephew and close friend of George Ticknor, the historian of Spanish literature, and his association with his uncle was influential in developing his scholarly tastes; while his other personal friendships with eminent Bostonians during the period of conservative Whig ascendancy in Massachusetts politics were of direct influence upon his political opinions and published estimates. He is best known as the author of *A History of the Origin, Formation and Adoption of the Constitution of the United States, with Notices of its principal Framers* (1854), republished, with many additions, as *The Constitutional History of the United States, from their Declaration of Independence to the Close of their Civil War* (2 vols., 1889-1890). This history, which had been watched in its earlier progress by Daniel Webster, may be said to present the old Federalist or "Webster-Whig" view of the formation and powers of the Constitution; and it was natural that Curtis should follow it with
a voluminous Life of Daniel Webster (2 vols., 1870), the most valuable biography of that statesman. Both these works are characterized by solidity and comprehensiveness rather than by rhetorical, attractive or literary perspective. In his later years Mr. Curtis, like so many of the followers of Webster, turned towards the Democratic party, and he wrote, among other works of minor importance, an expository life of President James Buchanan (2 vols., 1883) and two vindications of General George B. McClellan's career (1886 and 1887). He died in New York on the 28th of March 1894.

In addition to the works above mentioned he published: Digest of the English and American Admiralty Decisions (1839); Rights and Duties of Merchants and Seamen (1841), which elicited the hearty praise of Justice Joseph Story; Law of Patents (1849); Equity Precedents (1850); Commentaries on the Jurisprudence, Practice and Peculiar Jurisdiction of the Courts of the United States (1854-1858); Creation or Evolution: A Philosophical Inquiry (1887); and a novel, John Chambers; A Tale of the Civil War in America (1888).

His brother, Benjamin Robbins Curtis (1809-1874), also an eminent jurist, was born on the 4th of November 1809, in Watertown, Massachusetts, graduated at Harvard in 1829, studied law at Cambridge and at Northfield, Mass., where, after his admission to the bar in 1832, he practised law for two years, and then in Boston in 1834-1831. In 1831, being then a member of the lower house of the Massachusetts legislature, he was on the 22nd of September appointed to the Supreme Court of the United States, where he gained his greatest fame in 1837 by his dissenting opinion in the Dred Scott case, in which he argued that the Missouri Compromise was constitutional, and that negroes could become citizens. His argument was immediately published as an anti-slavery document. On the 1st of September 1857 he resigned from the Supreme Court and resumed his private practice. In 1868 he was one of the counsel for President Andrew Johnson in his impeachment trial, and opened for the defence in a remarkable two-days' speech. He died at Newport, Rhode Island, on the 15th of September 1874. He collected Decisions of the Supreme Court (20 vols.) and a Digest of its decisions down to 1854.

CURTIS, GEORGE WILLIAM (1824-1892), American man of letters, was born in Providence, Rhode Island, on the 14th of February 1824, of old New England stock. His mother died when he was but two years old. At six he was sent with his elder brother to school in Jamaica Plain, Massachusetts, where he remained for five years. Then, his father having again married happily, the boys were brought home to Providence, where they stayed till, in 1839, their father removed to New York. Three years later, Curtis, being allowed to determine for himself course of life, and being in sympathy with the spirit of the so-called Transcendental movement, became a boader at the community of Brook Farm. He was accompanied by his brother, James Burrill Curtis, whose influence upon him was strong and helpful. He remained there for two years, brought into stimulating and serviceable relations with many interesting men and women. Then came two years, passed partly in New York, partly in Concord in order mainly to be in the friendly neighborhood of Emerson, and then followed four years spent in Europe, Egypt and Syria.

Curtis returned from Europe in 1850, handsome, attractive, accomplished, ambitious of literary distinction. He instantly plunged into the whirl of life in New York, obtained a place on the staff of the Tribune, entered the field as a popular lecturer, set himself to work on a volume of travels, entitled in 1851, under the title of Notes of a Houdaifi, and became a favourite in society. He wrote much for Putnam's Magazine, of which he was associate editor; and a number of volumes, composed of essays written for that publication and for Harper's Monthly, came in rapid succession from his pen. The chief of these were the Poliphilus Papers (1853), a satire on the fashionable society of the day; and Prue and I (1856), a pleasantly sentimental, fancifully tender and humorous study of life. In 1855 he married Miss Anna Shaw. Not long after his marriage he became, through no fault of his own, deeply involved in debt owing to the failure of Putnam's Magazine; and his high sense of honour compelled him to devote the greater part of his earnings for many years to the discharge of obligations for which he had become only by accident responsible, and from which he might have freed himself by legal process. In the period just preceding the Civil War other interests became subordinate to those of national concern. Curtis made his first important speech on the questions of the day at Wesleyan University in 1856; he engaged actively in the presidential campaign of that year, and was soon recognized not only as an effective public speaker, but also as one of the ablest, most high-minded, and most trustworthy leaders of public opinion. In 1863 he became the political editor of Harper's Weekly, and no other journal exercised during the war and after it a more important part in shaping public opinion. His writing was always clear, direct, forcible; his fairness of mind and sweetness of temper were invincible. He never became a mere partisan, and never failed to apply the test of moral principle to political measures. From month to month he contributed to Harper's Monthly, under the title of "The Easy Chair," brief essays on topics of social and literary interest, charming in style, touched with delicate humour and instinct with generous spirit. His service to the Republican party was such, that more than once he offered himself for political station at a high distinction, and might have been sent as minister to England; but he refused all offers of the kind, feeling that he could render more essential service to the country as editor and public speaker.

In 1871 he was appointed by President Grant chairman of the commission to report on the reform of the civil service. The report which he wrote was the foundation of every effort since made for the purification and regulation of the service and for the destruction of political patronage. From that time till his death Curtis was the leader in this reform, and to his sound judgment, his vigorous presentation of the evils of the corrupt prevailing system, and his unflagging efforts, the progress of the reform is mainly due. He was president of the National Civil Service Reform League and of the New York Civil Service Reform Association. In 1884 he refused to support the nomination of James G. Blaine as candidate for the presidency, and thus broke with the Republican party, of which he had been one of the founders and leaders. From that time he stood as the typical independent in politics. In April 1892 he delivered at Baltimore his eleventh annual address as president of the National Civil Service Reform League, and in May he appeared for the last time as the greatest leader of the Young America in New York—an able and patient legislator, James Russell Lowell, which he had first delivered in Brooklyn on the 22nd of the preceding February, the anniversary of Lowell's birth. On the 31st of the following August he died. He was a man of consistent virtue, whose face and figure corresponded with the traits and stature of his soul. The grace and charm of his manner were the expression of his nature. Of the Americans of his time few were more widely beloved, and the respect in which he was held was universal.

undertaking a further journey to Greece in 1862, Curtius was appointed (in 1863) ordinary professor at Berlin. In 1874 he was sent to Athens by the German government, and concluded an agreement by which the excavations at Olympia (q.v.) were entrusted exclusively to Germany. Curtius died at Berlin on the 11th of July 1896. His best-known work is his History of Greece (1857-1867, 6th ed. 1887-1888; Eng. trans. by A. W. Ward, 1868-1873). It presented in an attractive style what were then the latest results of scholarly research, but was criticized as wanting in erudition. It is now superseded (see GREECE: History, Ancien, § Bibliography). His other writings are chiefly archaeological. The most important are: Die Aekropolis von Athen (1844); Naxos (1846); Peloponnesos, eine historisch-geographische Beschreibung der Halbinsel (1851; Olympia (1852); Die Ionier vor der ionischen Wanderung (1855); Alte Studien (1852-1865); Ephesos (1874); Die Ausgrabungen zu Olympia (1877, &c.); Olympia and Umgebung (edited by Curtius and F. Adler, 1882); Olympia. Die Ergebnisse der von dem deutschen Reich veranstalteten Ausgrabung (with F. Adler, 1890-1898); Die Stadthistorische von Athen (1861); Gesammelte Abhandlungen (1894). His collected speeches and lectures were published under the title of Altertum und Gegenwart (5th ed., 1903 foll.); three of them have been added under the title of Unter drei Kaiser (2nd ed., 1895).

A full list of his writings will be found in L. Gurlitt, Erinnerungen an Ernst Curtius (Berlin, 1902); see also article by O. Kern in Allgemeine deutsche Biographie, xlvii. (1903), to which may be added Ernst Curtius. Ein Lebensbild in Briefen, by F. Curtius (1903); T. Hodgkinson, Curtius (1905).

His brother, Georg Curtius (1820-1885), philologist, was born at Lübeck on the 16th of April 1820. After an education at Bonn and Berlin he was for three years a schoolmaster in Dresden, until (in 1845) he returned to Berlin University as privat-docent. In 1849 he was placed in charge of the Philological Seminary at Prague, and two years later was appointed professor of classical philology in Prague University. In 1854 he removed from Prague to a similar appointment at Kiev, and again in 1862 from Kiev to Leipzig. He died at Hemsdorf on the 12th of August 1885. His philological theories exercised a widespread influence. The more important of his publications are: Die Sprachvergleichung in ihrem Verhältniss zur classicen Philologie (1845; Eng. trans. by F. H. Trithen, 1851); Sprachvergleichende Beiträge zur griechischen und lateinischen Grammatik (1846); Grundzüge der griechischen Elymologie (1858-1862, 5th ed. 1879); Das Verbum der griechischen Sprache (1852); and Das Romanische (1854-1859) (two works have been translated into English by S. Wilkins and E. B. England). From 1878 to his death Curtius was general editor of the Leipziger Studien zur classicen Philologie. His Griechische Schulgrammatik, first published in 1852, has passed through more than twenty editions, and has been edited in English. In his last work, Zur Kritik der neuesten Sprachforschung (1885), he attacks the views of the "new" school of philology.

Opuscula of Georg Curtius were edited after his death by E. Windisch (Kleine Schriften von E. C., 1886-1887). For further information consult articles by R. Meister in Allgemeine deutsche Biographie, and by E. Windisch in C. Burian's Biographisches Jahrbuch fur Alterthumskunde (1886).

Curtius, Marcus, a legendary hero of ancient Rome. It is said that in 352 b.c. a deep gulf opened in the forum, which the seers declared would never close until Rome's most valuable possession was thrown into it. Then Curtius, a youth of noble family, recognizing that nothing was more precious than a brave citizen, leaped, fully armed and on horseback, into the chasm, which immediately closed again. The spot was afterwards covered by a marl called the Lactus Curtius. There are two explanations of the name Lactus Curtius are given: (1) a Sabinian general, Mettius (or Mettus) Curtius, hard pressed by the Romans under Romulus, leaped into a swamp which covered the valley afterwards occupied by the forum, and barely escaped with his life; (2) in 445 b.c. the spot was struck by lightning, and enclosed as sacred by the consul, Gaius Curtius. It was marked by an altar which was removed to make room for the games in celebration of Caesar's funeral (Pliny, Nat. Hist. xv. 77), but restored by Augustus (cf. Ovid, Fasti, vi. 493), in whose time there was apparently nothing but a dry well. The altar seems to have been restored early in the 4th century a.d. In 1904, on the N. side of the Via Sacra and 20 ft. N.W. of the Equus Domitianus, remains of the buildings were discovered.

See Livy i. 12, vii. 6; Dion Halic. ii. 42; Varro, De lingua Latina, v. 148; Ch. Hülsen, The Roman Forum (Eng. trans. of 2nd ed., J. B. Carter, 1906); O. Gilbert, Geschichte und Topographie der Stadt Rom im Altertum, i. (1883). 334-338.

Curtius Rufus, Quintus, biographer of Alexander the Great. Of his personal history nothing is known, nor can his date be fixed with certainty. Modern authorities regard him as a rhetorician who flourished during the reign of Claudius (a.d. 41-54). His work (De Rebus gestis Alexandri Magi) originally consisted of ten books, of which the first two are entirely lost, and the remaining eight are incomplete. Although the work is uncritical, and shows the author's ignorance of geography, chronology and military matters, it is written in a picturesque style.

There are numerous editions: (text) T. Vogel (1889), P. H. Damste (1897), E. Hedicke (1908); (with notes), T. Vogel (1885 and later), M. Croiset (1885), H. W. Reich (1895), C. Lebaugué (1900), T. Stangl (1902). There is an English translation by F. Fratt (1921). See S. S. Spinola, De Curtio, sa vie, et ses œuvres (1887) a valuable work; F. Von Schwarz, Alexander des Grossen Feldzüge in Turkistan (1893), a commentary on Arrian and Curtius based upon the author's personal knowledge of the topography; W. Wachsmuth, Einleitung in das Studium der alten Geschichte (1862), p. 574, cf. p. 657, note 2; Schwarz, "Curtius Rufus" No. 31 in Pauly-Wissowa (1901).

Curule (Lat. currus, "chariot"), in Roman antiquities, the epithet applied to the chair of office, sella curritus, used by the "curule" or highest magistrates and also by the emperors. This chair seems to have been originally placed in the magistrate's chariot (hence the name). It was inlaid with ivory or in some cases made of it, had curved legs but no back, and could be folded up like a camp-stool. In English the word is used in the general sense of "official." (See Consul, Praetor and Aedile.)

Curule (Lat. currous, Ancient word commonly meaning a shelf or foundation, represented by a line bending continuously out of the straight without making an angle, but only properly to be defined in its geometrical sense in the terms set out below. This subject is treated here from an historical point of view, for the purpose of showing how the different leading ideas were successively arrived at and developed. 1. A curve is a line, or continuous singly infinite system of points. We consider in the first instance, and chiefly, a plane curve described according to a law. Such a curve may be regarded geometrically as actually described, or kinematically as in the course of description by the motion of a point; in the former point of view, it is the locus of all the points which satisfy a given condition; in the latter, it is the locus of a point moving subject to a given condition. Thus the simplest and earliest known curve, the circle, is the locus of all the points at a given distance from a fixed centre, or else the locus of a point moving so as to be always at a given distance from a fixed centre. (The straight line and the point are not for the moment regarded as curves.)

Next to the circle we have the conic sections, the invention of them attributed to Plato (who lived 430-347 B.C.); the original definition of them as the sections of a cone was by the Greek geometers who studied them soon replaced by a proper definition in plano like that for the circle, viz. a conic section (or as we now say a "conic") is the locus of a point such that its distance from a given point, the focus, is in a given ratio to its (perpendicular) distance from a given line, the directrix; or it is the locus of a point which moves so as always to satisfy the foregoing condition. Similarly any other property might be used as a definition; an ellipse is the locus of a point such that the sum of its distances from two fixed points (the foci) is constant, &c., &c.

The Greek geometers invented other curves; in particular, the conchoid (q.v.), which is the locus of a point such that its distance from a given line, measured along the line drawn through
it to a fixed point, is constant; and the cissoid (q.n.) which is the locus of a point such that its distance from a fixed point is always equal to the intercept (on the line through the fixed point) between a circle passing through the fixed point and the tangent to the circle at the point opposite to the fixed point. Obviously the number of such geometrical or kinematical definitions is infinite. In a machine of any kind, each point describes a curve; a simple but important instance is the "three-bar curve," or locus of a point in or rigidly connected with a bar pivoted on to two other bars which rotate about fixed centres respectively. Every curve thus arbitrarily defined has its own properties; and there was not any principle of classification.

2. Cartesian Co-ordinates.—The principle of classification first presented itself in the \textit{Géométrie} of Descartes (1637). The idea was to represent any curve whatever by means of a relation between the co-ordinates \((x, y)\) of a point of the curve, or say to represent the curve by means of its equation. (See \textit{Geometry: Analytical}.)

Any relation whatever between \((x, y)\) determines a curve, and conversely every curve whatever is determined by a relation between \((x, y)\). Of these the distinctive feature is the \textit{exclusive} use of such determination of a curve by means of its equation. The Greek geometers were perfectly familiar with the property of an ellipse which in the Cartesian notation is \(x^2/a^2+y^2/b^2=1\), the equation of the curve; but it was as one of a number of properties, and in no wise selected out of the others for the characteristic property of the curve.

3. Order of a Curve.—We obtain from the equation the notion of an algebraical as opposed to a transcendental curve, viz. an algebraical curve is a curve having an equation \(F(x, y)=0\) where \(F(x, y)\) is a rational and integral function of the co-ordinates \((x, y)\); and in what follows we attend throughout (unless the contrary is stated) only to such curves. The equation is sometimes given, and may conveniently be used, in an irrational form, but we always imagine it reduced to the foregoing rational and integral form, and regard this as the equation of the curve. And we have hence the notion of a curve of a \textit{given order}, viz. the order of the curve is equal to that of the term of highest order in the co-ordinates \((x, y)\) conjointly in the equation of the curve; for instance, \(2x-1=0\) is a first order curve.

It is to be noticed here that the axes of co-ordinates may be any two lines at right angles to each other whatever; and that the equation of a curve will be different according to the selection of the axes of co-ordinates; but the order is independent of the axes, and has a determinate value for any given curve.

We hence divide curves according to their order, viz. a curve is of the first order, second order, third order, \&c., according as it is represented by an equation of the first order, \(ax+by+c=0\), or say \((y \times x, y, 1)=0\); or by an equation of the second order, \(ax^2+2hxy+y^2+2gxz+c=0\), say \((y \times x, y, 1)^2=0\); or by an equation of the third order, \&c.; or what is the same thing, according as the equation is linear, quadric, cubic, \&c.

A curve of the first order is a right line; and conversely every right line is a curve of the first order. A curve of the second order is a conic, and is also called a quadric curve; and conversely every conic is a curve of the second order or quadric curve. A curve of the third order is called a cubic; one of the fourth order a quartic; and so on.

A curve of the order \(m\) has for its equation \((y \times x, y, 1)^m=0\); and from this the determination of the function is arbitrary; the curve is said to be the general curve of the order \(m\). The number of coefficients is \(\frac{1}{2}(m+1)(m+2);\) but there is no loss of generality if the equation be divided by one coefficient so as to reduce the coefficient of the corresponding term to unity, hence the number of coefficients may be reckoned as \(\frac{1}{2}(m+1)(m+2)-1\), that is, \(\frac{1}{2}m(m+3);\) and a curve of the order \(m\) may be made to satisfy this number of conditions; for example, to pass through \(\frac{1}{2}m(m+3)\) points.

It is to be remarked that an equation may break up; thus a quadratic equation may be \((ax+by+c)\ (a'x+b' y+c')=0\), breaking up into two equations \(ax+by+c=0, a'x+b' y+c'=0\). The original equation is satisfied if either of these is satisfied. Each of these last equations represents a curve of the first order, or right line; and the original equation represents this pair of lines, viz. the pair of lines is considered as a quadric curve. But it is an \textit{improper} quadric curve; and in speaking of curves of the second or any other given order, we frequently imply that the curve is a proper curve represented by an equation which does not break up.

4. Intersections of Curves.—The intersections of two curves are obtained by combining their equations; viz. the elimination from the two equations of \((y\ or x)\) gives for \((y\ or x)\) an equation of a certain order, say the resultant equation; and then to each value of \((x\ or y)\) satisfying this equation there corresponds in general a single value of \((y\ or x)\), and consequently a single point of intersection; the number of intersections is thus equal to the order of the resultant equation in \((y\ or x)\).

Supposing that the two curves are of the orders \(m, n\), respectively, then the order of the resultant equation is in general and at most \(mn\); in particular, if the curve of the order \(n\) is an arbitrary line \((n=1)\), then the order of the resultant equation is \(2\); and the curve of the order \(m\) meets therefore the line in \(m\) points. But the resultant equation may have all or any of its roots imaginary, and it is thus not always that there are \(m\) real intersections.

The notion of imaginary intersections, thus presenting itself, through algebra, in geometry, must be accepted in geometry—and it in fact plays an all-important part in modern geometry. As in algebra we say that an equation of the \(m\)th order has \(m\) roots, viz. we state this generally without in the first instance, or it may be without ever, distinguishing whether these are real or imaginary; so in geometry we say that a curve of the \(m\)th order is met by an arbitrary line in \(m\) points, or rather we thus, through algebra, obtain the proper geometrical definition of a curve of the \(m\)th order, as a curve which is met by an arbitrary line in \(m\) points (that is, of course, in \(m\), and not more than \(m\), points).

The theorem of the \(m\) intersections has been stated in regard to an \textit{arbitrary} line; in fact, for particular lines the resultant equation may be or appear to be of an order less than \(m\); for instance, taking \(m=2\), if the hyperbola \(xy-1=0\) be cut by the line \(y=\beta\), the resultant equation in \(x\ is\ \beta x-1=0\), and there is accordingly only one point intersection \((x=\beta, y=\beta)\); but the theorem is, in fact, true for every line whatever: a curve of the order \(m\) meets every line whatever in precisely \(m\) points. We have, in the case just referred to, to take account of a point at infinity on the line \(y=\beta\); the two intersections are the point \((x=1/\beta, y=\beta)\), and the point at infinity on the line \(y=\beta\).

It is, moreover, to be noticed that the points at infinity may be all or any of them imaginary, and that the points of intersection, whether finite or at infinity, real or imaginary, may coincide two or more of them together, and have to be counted accordingly; to support the theorem in its universality, it is necessary to take account of these various circumstances.

5. Line at Infinity.—The foregoing notion of a point at infinity is a very important one in modern geometry; and we have also to consider the paradoxical statement that in plane geometry, or say as regards the plane, infinity is a right line. This admits of an easy illustration in solid geometry. If with a given centre of projection, by drawing from it lines to every point of a given line, we project the given line on a given plane, the projection is \(i, \text{i.e. this projection is the intersection of the given plane with the plane through the centre and the given line.}\) If the projection is always a line, then if the figure is such that the two planes are parallel, the projection is the intersection of the given plane by a parallel plane, or it is the system of points at infinity on the given plane, that is, these points at infinity are regarded as situate on a given line, the line infinity of the given plane.1

---

1 In solid geometry infinity is a plane—its intersection with any given plane being the right line which is the infinity of this given plane.
Reverting to the purely plane theory, infinity is a line, related like any other right line to the curve, and thus intersecting it in \( m \) points, real or imaginary, distinct or coincident.

Descartes in the *Géométrie* defined and considered the remarkable curves called after him the ovals of Descartes, or simply Cartesian, which will be again referred to. The next important work, founded on the *Géométrie*, was Sir Isaac Newton's *Enumeratio linearum tertii ordinis* (1706), establishing a classification of cubic curves founded chiefly on the nature of their infinite branches, which was in some details completed by James Stirling (1692–1770), Patrick Murdoch (d. 1774) and Gabriel Cramer; the work also contains the remarkable theorem (to be again referred to), that there are five kinds of cubic curves giving by their projections every cubic curve whatever. Various properties of curves in general, and of cubic curves, are established in Colin Maclaurin's memoir, "De lineum geometricarum proprietatibus generalibus Tractatus" (posthumous, say 1746, published in the 6th edition of his *Algebra*).

We have in it a particular kind of correspondence of two points on a cubic curve, viz. two points correspond to each other when the tangents at the two points again meet the cubic in the same point.

6. Reciprocal Polars. Intersections of Circles. Duality. Trilinear and Tangential Co-ordinates. The *Géométrie* descriptive, by Gaspard Monge, was written in the year 1794 or 1795 (7th edition, Paris, 1847), and in it we have stated, in *planum* with regard to the circle, and in three dimensions with regard to a surface of the second order, the fundamental theorem of reciprocal polars, viz. "Given a surface of the second order and a circumscried conic surface which touches it... then if the conic surface moves so that its summit is always in the same plane, the plane of the curve of contact passes always through the same point."

The theorem is here referred to partly on account of its bearing on the theory of imaginaries in geometry. It is in Charles Julian Brachon's memoir "Sur les surfaces du second degré" (Jour. Polyt. t. vi. 1806) shown how for any given position of the plane of contact is determined, or reciprocally; say the plane \( XYZ \) is determined when the point \( P \) is given, or reciprocally; and it is noticed that when \( P \) is situated in the interior of the surface the plane \( XYZ \) does not cut the surface; that is, we have a real plane \( XY \) intersecting the surface in the imaginary curve of contact of the imaginary circumscribed cone having for its summit a given real point \( P \) inside the surface.

Stating the theorem in regard to a conic, we have a real point \( P \) (called the pole) and a real line \( XY \) (called the polar), the line joining the two (real or imaginary) points of contact of the (real or imaginary) tangents drawn from the point to the conic; and the theorem is that when the point describes a line the line passes through a point, this line and point being polar and pole to each other. The term "pole" was first used by François Joseph Servois, and "polar" by Joseph Diez Gergonne (Gerg. t. i. and iii., 1810–1813); and from the theorem we have the method of reciprocal polars for the transformation of geometrical theorems by Brianchon (in the memoir above referred to) for the demonstration of the theorem called by his name, and in a similar manner by various writers in the earlier volumes of Gergonne. We are here concerned with the method less in itself than as leading to the general notion of duality.

Bearing in a somewhat similar manner also on the theory of imaginaries in geometry (but the notion presents itself in a more explicit form), there is the memoir by L. Gaultier, on the graphical construction of circles and spheres (Jour. Polyt. t. ix., 1813). The well-known theorem as to radical axes may be stated as follows.

Consider two circles partially drawn so that it does not appear whether the circles, if completed, would or would not intersect in real points, say two arcs of circles; then we can, by means of a third circle drawn so as to intersect in two real points each of the two arcs, determine a right line, which, if the complete circles intersect in two real points, passes through the points, and which is on this account regarded as a line passing through two (real or imaginary) points of intersection of the two circles. The construction in fact is, join the two points in which the third circle meets the first arc, and join also the two points in which the third circle meets the second arc, and from the point of intersection of the two joining lines, let fall a perpendicular on the line joining the centre of the two circles; this perpendicular (considered as an indefinite line) is what Gaultier terms the "radical axis of the two circles"; it is a line determined by a real construction and itself always real; and by what precedes it is the line joining two (real or imaginary, as the case may be) intersections of the given circles.

The intersections which lie on the radical axis are two out of the four intersections of the two circles. The question as to the remaining two intersections did not present itself to Gaultier, but it is answered in Jean Victor Poncelet's *Traité des propriétés projectives* (1822), where we find (p. 49) the statement, "deux circles placés arbitrairement sur un plan... ont idéalement deux points imaginaires communs à l'infini"; that is, a circle *qua* curve of the second order is met by the line infinity in two points; but, more than this, they are the same two points for any circle whatever. The points in question have since been called (it is believed first by Dr George Salmon) the circular points at infinity, or they may be called the circular points; these are also frequently spoken of as the points \( I, J \); and we have thus the circle characterized as a conic which passes through the two circular points at infinity; the number of conditions thus imposed upon the conic is \( m = 2 \), and there remain three arbitrary constants, which is the right number for the circle. Poncelet throughout his work makes continual use of the foregoing theories of imaginaries and infinity, and also of the before-mentioned theory of reciprocal polars.

Poncelet's two memoirs *Sur les centres des moyennes harmoniques* and *Sur la théorie générale des polaires réciproques*, although presented to the Paris Academy in 1824, were only published (Crelle, t. iii. and iv., 1828, 1829) subsequent to the memoir by Gergonne, *Considérations philosophiques sur les éléments de la science de l'étendue* (Gerg. t. xvi., 1825–1826). In this memoir by Gergonne, the theory of duality is very clearly and explicitly stated; for instance, we find "dans la géométrie plane, à chaque théorème il en répond nécessairement un autre qui s'en déduit en échangeant simplement entre eux les deux mots points et droites; tandis que dans la géométrie de l'espace ce sont les mots points et plans qu'il faut échanger entre eux pour passer d'un théorème à son corrélatif"; and the plan is introduced of printing correlative theorems, opposite to each other, in two columns. There was a reclamation as to priority by Poncelet in the *Bulletin universel* reprinted with remarks by Gergonne (Gerg. t. xix., 1827), and followed by a short paper by Gergonne, *Rectifications de quelques théorèmes*, etc., which is important as first introducing the word *class*. We find in it explicitly the two correlative definitions: "a plane curve is said to be of the \( m \)th degree (order) when it has with a line \( m \) real or ideal intersections," and "a plane curve is said to be of the \( m \)th class when from any point of its plane there can be drawn to it \( m \) real or ideal tangents."

It may be remarked that in Poncelet's memoir on reciprocal polars, above referred to, we have the theorem that the number of tangents from a point to a curve of the order \( m \), or say the class of the curve, is in general and at most \( m(m-1) \), and that he mentions that this number is subject to reduction when the curve has double points or cusps.

The theorem of duality as regards plane figures may be thus stated: two figures may correspond to each other in such manner that to each point and line in either figure there correspond in the other figure a line and point respectively. It is to be understood that the theorem extends to all points or lines, drawn or not drawn; thus if in the first figure there are any number of points on a line drawn or not drawn, the corresponding lines in the second figure, produced if necessary, must meet in a point. And we thus see how the theorem extends to curves, their points and tangents; if there is in the first figure a curve of the order \( m \), any line meets it in \( m \) points; and hence from the corresponding point in the second figure there must be to the corresponding curve \( m \) tangents; that is, the corresponding curve must be of the class \( m \).
7. Singularities of a Curve. Plücker's Equations.—The above general derivation explains the nature of the singularities of a plane curve. The ordinary singularities, arranged according to a cross division, are

Point-singularities—
1. The stationary point, 2. The double point—

Line-singularities—
3. The stationary tangent, 4. The double tangent—

arising as follows:
1. The cusp: the point as it travels along the line may come to rest, and then reverse the direction of its motion.
2. The stationary tangent: the line may in the course of its rotation come to rest, and then reverse the direction of its rotation.
3. The node: the point may in the course of its motion come to coincide with a former position of the point, the two positions of the line in that case being coincident.
4. The double tangent: the line may in the course of its motion come to coincide with a former position of the line, the two positions of the point not in general coincident.

It may be remarked that we cannot with a real point and line obtain the node with two imaginary tangents (conjugate or isolated point or acnode), nor again the real double tangent with two imaginary points of contact; but this is of little consequence, since in the general theory the distinction between real and imaginary is not attended to.

The singularities (1) and (3) have been termed proper singularities, and (2) and (4) improper; in each of the first-mentioned cases there is a real singularity, or peculiarity in the motion; in the other two cases there is general coinciding (2) there is not when the point is first at the node, or when it is secondly at the node, any peculiarity in the motion; the singularity consists in the point coming twice into the same position; and in (4) the singularity is in the line coming twice into the same position. Moreover (1) and (2) are, the former a proper singularity, and the latter an improper singularity, as regards the motion of the point; and similarly (3) and (4) are, the former a proper singularity, and the latter an improper singularity, as regards the motion of the line.

But as regards the representation of a curve by an equation, the case is very different.

First, if the equation be in point-co-ordinates, (3) and (4) are in a sense not singularities at all. The curve (\(yx, y, z) = 0\), or general curve of the order \(m\), has double tangents and inflections; (2) presents itself as a singularity, for the equations \(a_y(x, y, z) = 0, a_x(x, y, z) = 0\), implying \(a_y(y, z) = 0\), are not in general satisfied by any values of \((a, b, c)\) whatever of \((x, y, z)\), but if such values exist, then the point \((a, b, c)\) is a node or double point; and (1) presents itself as a further singularity or sub-case of (2), a cusp being a double point for which the two tangents become coincident.

In line-co-ordinates all is reversed:—(1) and (2) are not singularities; (3) presents itself as a sub-case of (4).

The theory of compound singularities will be referred to farther on.

In regard to the ordinary singularities, we have

- \(m\), the order,
- \(n\), class,
- \(q\), number of double points,
- \(r\), cusps,
- \(s\), double tangents,
- \(t\), inflections,

and this being so, Plücker's "six equations" are

\[
\begin{align*}
7n & = m(m-1) - 2b-3s; \\
n & = \frac{1}{3}(m-2)(m^2-9) - (m^2-6m-6) (3b+3s+2b-1) + 6k^2 + 3(x-k) \\
5n & = m(n-1) - 2b-3s; \\
4n & = \frac{1}{3}(m-2)(m-8s) - (m^2-6m-6) (2r+3s+2r-1) + 6r^2 + 3(x-1) \\
6n & = \frac{1}{3}(m-2)(m^2-9) - (m^2-6m-6) (2r+3s+2r-1) + 6m^2 + 3(x-1) \\
\end{align*}
\]

It is easy to derive the further forms—

\[
\begin{align*}
7b & = 3(m-n); \\
8b & = (2r-s); \\
9b & = 3n + 3s - 2; \\
10b & = (m-1)(m-2) - 2n + k \left( \frac{1}{3}(n-1)(n-2) - r + 1 \right) \\
11b & = \frac{1}{3}(m-2)(m^2-9) - (m^2-6m-6) (2r+3s+2r-1) + 6n^2 + 3(x-1) \\
\end{align*}
\]
the whole system being equivalent to three equations only; and
it may be added that using $a$ to denote the equal quantities
$3m + 1$ and $3n + k$ everything may be expressed in terms of $m, n, a, k$.
We have

$$\begin{align*}
\kappa &= a - 3n, \\
\iota &= a - 3m, \\
2b &= m^2 - m + 4k - 3a, \\
2r &= m^2 - 8m - 3a.
\end{align*}$$

It is implicated in Plücker's theorem that, $m, n, b, n, r, i$ signifying
as above in regard to any curve, then in regard to the reciprocal
curve, $n, m, n, b, n, r, i, \kappa$ will have the same significations, viz. for
the reciprocal curve these letters represent respectively the order, class,
number of nodes, cusps, double tangents and inflections.

The expression $\frac{1}{3} m (m - 3) - 3 - 3 \kappa$ is that of the number of
disposable constants in a curve of the order $m$ with $\kappa$ nodes and $\kappa$
cusps (in fact there shall be a node is $t$ condition, a cusp $2$ conditions,
and the equation $(q)$ thus expresses that the curve and its
reciprocal contain each of them the same number of disposable
constants.

For a curve of the order $m$, the expression $\frac{1}{3} m (m - 1) - 3 - 3 \kappa$ is
the "deficiency" (as to this more hereafter); the equation
$(10)$ expresses therefore that the curve and its reciprocal have each of
them the same deficiency.

The relations $m^2 - 2b = 3n = n^2 - 2r - 3i, m + n, p, q, r, s, t$ present themselves
in the theory of envelopes, as will appear farther on.

With regard to the demonstration of Plücker's equations it is
to be pointed out that we are not able to write down the equation
in point-co-ordinates of a curve of the order $m$, having the given
numbers $\delta$ and $\kappa$ of nodes and cusps. We can only use the general
equation (*$8x, y, z, w =$ *) 0, say for shortness $u =$ 0, of a curve of the $m$th
order, which equation, so long as the coefficients remain
arbitrary, represents a curve without nodes or cusps. Seeking
then, for this curve, the values, $p, q, r, t$, of the class, number
of inflections, and number of double tangents,—first, as regards
the class, this is equal to the number of tangents which can be
drawn to the curve from an arbitrary point, or what is the same
thing, it is equal to the number of the points of contact of these
tangents. The points of contact are found as the intersections of
the curve $u =$ 0 by a curve depending on the position of the
arbitrary point, and called the "first polar" of this point;
the order of the first polar is $m - 1$, and the number of
intersections is thus $m (m - 1)$. But it can be shown, analytically
or geometrically, that if the given curve has a node, the first
polar passes through this node, which therefore counts as two
intersections; and that if the curve has a cusp, the first
polar passes through the cusp, touching the curve there, and hence
the cusp counts as three intersections. But, as is evident, the
node or cusp is not a point of contact of a proper tangent from
the arbitrary point; we have, therefore, for a node a diminution 2, and
for a cusp a diminution 3, in the number of the intersections;
and thus, for a curve with $\delta$ nodes and $\kappa$ cusps, there is a diminution
$2b + 3 \kappa$, and the value of $n$ is $n = m (m - 1) - 2b - 3 \kappa$.

Secondly, as to the inflections, the process is a similar one; it
can be shown that the inflections are the intersections of the
curve by a derivative curve called (after Ludwig Otto Hesse
who first considered it) the Hessian, defined geometrically as
the locus of a point such that its conic polar (§ 8 below) in regard
to the curve breaks up into a pair of lines, and which has an
equation $H =$ 0, where $H$ is the determinant formed with
the second differential coefficients of $u$ in regard to the variables
$z, y, z$; $H =$ 0 is thus a curve of the order $3 (m - 2)$, and the
number of inflections is $3m (m - 2)$. But if the given curve
has a node, then not only the Hessian passes through the node,
but it has there a node the two branches at which touch respec-
tively the two branches of the curve; and the node thus
counts as six intersections; so if the curve has a cusp, then the
Hessian not only passes through the cusp, but it has there a cusp
through which it again passes, that is, there is a cuspidal branch
touching the cuspidal branch of the curve, and besides a simple
branch passing through the cusp, and hence the cusp counts as
eight intersections. The node or cusp is not an inflection, and we
have thus for a node a diminution 6, and for a cusp a diminution 8,
in the number of the intersections; hence for a curve with $\delta$ nodes
and $\kappa$ cusps, the diminution is $6 \delta + 8 \kappa$, and the number of
inflections is $n = 3m (m - 2) - 6 \delta - 8 \kappa$.

Thirdly, for the double tangents; the points of contact of

these are obtained as the intersections of the curve by a curve
$\Pi =$ 0, which has not as yet been geometrically defined, but which
is found analytically to be of the order $m (m - 2)$; but if the
given curve has a node then there is a diminution $m (m - 2)$, and
if it has a cusp then there is a diminution $6 (m - 2)$; of these,
however, it is to be noticed that the factor $m (m - 2)$ is
in the case of a curve having only a node or only a cusp the
number of the tangents which can be drawn from the node or cusp
to the curve, and is used as denoting the number of these tangents,
and ceases to be the correct expression if the number of nodes
and cusps is greater than unity. Hence, in the case of a curve
which has $\delta$ nodes and $\kappa$ cusps, the apparent diminution
$2 (m - 6) (m - 6)$ is too great, and it has in fact to be diminished by
$2 (8 \delta + 8 \kappa (m - 1)]$, or the half thereof $4$ for each pair of nodes, $6$ for each combination of a node and
and $g$ for each pair of cusps. We have thus finally an expression
for $2r = m (m - 2) (m - 3) - 8 \kappa$, or dividing the whole
by $2r$, we have the expression $r$ given by the third of Plücker's
equations.

It is obvious that we cannot by consideration of the equation
$u =$ 0 in point-co-ordinates obtain the remaining three of Plücker's
equations; they might be obtained in a precisely analogous
manner by means of the equation $w =$ 0 in line-co-ordinates, but they
follow at once from the principle of duality. viz. they are obtained
by the mere interchange of $m, \delta, \kappa$ with $n, \tau, \iota$ respectively.

To complete Plücker's theory it is necessary to take account
of compound singularities; it might be possible, but it is at any
rate difficult, to effect this by considering the curve as in course of
description by the point moving along the rotating line; and it
seems easier to consider the compound singularity as arising
from the variation of an actually described curve with ordinary
singularities. The most simple case is when three double points
come into coincidence, thereby giving rise to a triple point;
and a somewhat more complicated one is when we have a cusp
of the second kind, or node-cusp arising from the coincidence of
a node, a cusp, an inflection, and a double tangent, as shown
in the annexed figure, which represents the singularities as on the
point of coalescing. The general conclusion (see Cayley, Quart.
Math. Jour. t. vii. 1866, 14 On the higher singularities of plane
curves*; Collected Works, v. 520) is that every singularity
whatever may be considered as compounded of ordinary
singularities, say we have a singularity $= 0$-nodes, $\kappa$ cusps, $r'$ double
tangents and $t'$ inflections. So that, in fact, Plücker's equations
properly understood apply to a curve with any singularities
whatever.

By means of Plücker's equations we may form a table—

---

**Collected Works, v. 520**
The table is arranged according to the value of $m$; and we have $m=0$, $n=1$, the point; $m=1$, $n=0$, the line; $m=2$, $n=1$, the conic; of $m=3$, the cubic, there are three cases, the class being 6, 4 or 3, according as the curve is without singularities, or as it has 1 node or 1 cusp; and so of $m=4$, the quartic, there are ten cases; and in the theory of two of them the class is $6$, the reduction of class arising from two cusps or else from three nodes. The ten cases may be also grouped together into four, according as the number of nodes and cusps $(\delta + \kappa)$ is $=0$, $1$, $2$, or $3$.

The cases may be divided into sub-cases, by the consideration of compound singularities; thus when $m=4$, $n=6$, $\delta =3$, the three nodes may all be distinct, which is the general case, or two of them may unite together into the singularity called a tacnode, or all three may unite together into a triple point or else into an oscnode.

We may further consider the inflections and double tangents, as well in general as in regard to cubic and quartic curves.

The expression for the number of inflections $3m(m-2)$ for a curve of the order $m$ was obtained analytically by Plücker, but the theory was first given in a complete form by Hesse in the two papers "Über die Elimination, u.s.w." and "Über die Wendepunkte der Curven dritter Ordnung" (Crelle, t. xxviii., 1844). A quartic curve has three inflections, as well as the intersections of the curve $u=0$ with the Hessian, or curve $A=0$, where $A$ is the determinant formed with the second derived functions of $u$. We have in the Hessian the first instance of a covariant of a ternary form. The whole formed with the inflections of a cubic curve is discussed in a very interesting manner by means of the canonical form of the equation $x^2 + y^2 + z^2 + dxz = 0$; and in particular a proof is given of Plücker’s theorem that the nine points of inflection of a cubic curve lie by threes in twelve lines.

It may be noticed that the nine inflections of a cubic curve represented by an equation with real coefficients are three real, six imaginary; the three real inflections lie in a line, as was known to Newton and Maclaurin. For an acnodal cubic the six imaginary inflections disappear, and there remain three real inflections lying in a line. For a crunodal cubic the six inflections which disappear are two of them real, the other four imaginary, and there remain two imaginary inflections and one real inflection. For a cuspidal cubic the six imaginary inflections and two of the real inflections disappear, and there remains one real inflection.

The inflections of a cubic curve; it was conjectured by George Salmon, and has been verified by H. G. Zeuthen that at most eight of these are real.

The expression $3m(m-2)(m^2-9)$ for the number of double tangents of a curve of the order $m$ was obtained by Plücker only as a consequence of his first, second, fourth, and fifth equations. An investigation by means of the curve $\Pi=0$, which by its intersections with the given curve determines the points of contact of the double tangents, is indicated by Cayley, “Recherches sur l’élimination et le théoreme des courbes” (Crelle, t. xxiv., 1847; Collected Works, vol. i. p. 337), and in part carried out by Hesse in the memoir “Über Curven dritter Ordnung” (Crelle, t. xxxvi., 1848). A better process was indicated by Salmon in the “Note on the Double Tangents to Plane Curves,” Phil. Mag., 1855; considering the $m-2$ points in which any tangent to the curve again meets the curve, he showed how to form the equation of a curve of the order $(m-2)$, giving by its intersection with the tangent the points in question; making the tangent touch this curve of the order $(m-2)$, it will be a double tangent of the original curve. See Cayley, “On the Double Tangents of a Plane Curve,” Phil. Trans., t. 1857, 1858; Collected Works, iv. 1860, and O. Dersch (Math. Ann. t. vii., 1874). The solution is still in so far incomplete that we have no properties of the curve $\Pi = 0$, to distinguish one such curve from the several other curves which pass through the points of contact of the double tangents.

A quartic curve has 28 double tangents, their points of contact determined as the intersections of the curve by a curve $\Pi = 0$ of the order 14, the equation of which in a very elegant form was first obtained by Hesse (1849). Investigations in regard to them are given by Plücker in the Théorie der algebraischen Curven, and in two memoirs by Hesse and Jacob Steiner (Crelle, t. xiv., 1855); in respect to the triads of double tangents which have their points of contact on a conic and other like relations. It was assumed by Plücker that the number of real double tangents might be 28, 16, 8, 4 or 0, but Zeuthen has found that the last case does not exist.

8. Invariants and Covariants. Polar Curves.—The Hessian $\Delta$ has just been spoken of as a covariant of the form $u$; the notion of invariants and covariants belongs rather to the form $u$ than to the curve $u=0$ represented by means of this form; and the theory may be very briefly referred to. A curve $u=0$ may have some invariant property, viz. a property independent of the particular axes of co-ordinates used in the representation of the curve by its equation; for instance, the curve may have a node, and in order to this, a relation, say $A=0$, must exist between the coefficients of the equation; supposing the axes of co-ordinates altered, so that the equation becomes $u'=o$, and writing $A'=0$ for the relation between the new coefficients, then the relations $A=0$, $A'=0$, as two different expressions of the same geometrical property, must each of them imply the other; this can only be the case when $A$, $A'$ are functions differing only by a constant factor, or say, when $A$ is an invariant of $u$. However, the geometrical property requires two or more relations between the coefficients, say $A=0$, $B=0$, &c., then we must have between the new coefficients the like relations, $A'=0$, $B'=0$, &c., and the two systems of equations must each of them imply the other; when this is so, the system of equations, $A=0$, $B=0$, &c., is said to be invariante, but it does not follow that $A$, $B$, &c., are of necessity invariants of $u$. Similarly, if we have a curve $U=0$ derived from the curve $u=0$ in a manner independent of the particular axes of co-ordinates, then from the transformed equation $u'=0$ deriving in like manner the curve $U'=0$, the two equations $U=0$, $U'=0$ must each of them imply the other; and when this is so, $U$ will be a covariant of $u$. The case is less frequent, but it may arise, that there are covariant systems $U=0$, $V=0$, &c., and $U'=0$, $V'=0$, &c., each implying the other, but where the functions $U$, $V$, &c., are not of necessity covariants of $u$.

If we take a fixed point $(x', y', z')$ and a curve $u=0$ of order $m$, and suppose the axes of reference altered, so that $x'$, $y'$, $z'$ are linearly transformed in the same way as the current $x$, $y$, $z$, the curves $(x' + y' + z') = 0$, $(r = 1, 2, \ldots, m-1)$ have the covariant property. They are the polar curves of the point with regard to $u=0$.

The theory of the invariants and covariants of a ternary cubic function $u$ has been studied in detail, and brought into connexion with the cubic curve $u=0$; but the theory of the invariants and covariants for the next succeeding case, the ternary quartic function, is still very incomplete.

9. Envelope of a Curve.—In further illustration of the Plückerian dual generation of a curve, we may consider the question of the envelope of a variable curve. The notion is very probably older, but it is at any rate to be found in Lagrange’s Théorie des fonctions analytiques (1788); it is there remarked that the equation obtained by the elimination of the parameter $a$ from an equation $f(x, y, a) = 0$ and the derived equation in respect to $a$ is a curve, the envelope of the series of curves represented by the equation $f(x, y, a) = 0$ in question. To develop the theory, consider that the curve corresponds to any particular value of the parameter; this has with the consecutive curves (or curves belonging to the consecutive values of $a$) a certain number of intersections and of common tangents, which may be considered as the tangents at the intersections; and the so-called envelope is the curve which is at the same time generated by the points of intersection and enveloped by the common tangents; we have thus a dual generation. But the question needs to be further examined. Suppose that in general the variable curve is of the order $m$ with $\delta$ nodes and $\kappa$ cusps, and therefore of the class $n$ with $\tau$ double tangents and $i$ inflections, $m, n, \delta, \kappa, \tau, i$ being connected by the Plückerian equations,—the number of nodes or cusps may be
greater for particular values of the parameter, but this is a
speciality which may be here disregarded. Considering the vari-
able curve corresponding to a given value of the parameter,
or say simply the variable curve, the consecutive curve has then
either \( \delta \) and \( \kappa \) nodes and cusps, consecutive to those of the variable
curve; and it is easy to see that among the intersections of the
two curves we have the nodes each counting twice, and the cusps
each counting three times; the number of the remaining inter-
sections is \( m^2 - 2 \delta - 3 \kappa \). Similarly among the common
tangents of the two curves we have the double tangents each
counting twice, and the stationary tangents each counting three times, and the number of the remaining common
tangents is \( m^2 - 2 \delta - 3 \kappa \) inasmuch as each of these numbers is as was seen \( m^2 + \kappa \). At any one of the \( m^2 - 2 \delta - 3 \kappa \) points the variable
curve and the consecutive curve have tangents distinct from yet
infinitely near to each other, and each of these two tangents is
also infinitely near to one of the \( m^2 - 2 \delta - 3 \kappa \) common
tangents of the two curves; whence, attending only to the
variable curve, and considering the consecutive curve as coming
into actual coincidence with it, the \( m^2 - 2 \delta - 3 \kappa \) common tangents
are the tangents to the variable curve at the \( m^2 - 2 \delta - 3 \kappa \) points
respectively, and the envelope is at the same time generated by
the \( m^2 - 2 \delta - 3 \kappa \) points of the variable curve; thus we have
a dual generation of the envelope, which only differs from Plücker's
dual generation, in that in place of a single point and tangent we have the group of \( m^2 - 2 \delta - 3 \kappa \) points and \( m^2 - 2 \delta - 3 \kappa \) tangents.

The parameter which determines the variable curve may be
given as a point upon a given curve, or say as a parametric
point; that is, to the different positions of the parametric point
on the given curve correspond the different variable curves, and
the nature of the envelope will thus depend on that of the
given curve; we have thus the envelope as a derivative curve of
the given curve. Many well-known derivative curves present
themselves in this manner; thus the variable curve may be
the normal (or line at right angles to the tangent) at any point
of the given curve; the intersection of the consecutive normals
is the centre of curvature; and we have the evolute as at once
the locus of the centre of curvature and the envelope of the
normal. It may be added that the given curve is one of a series
curves, each cutting the normals at right angles. Any one of
these curves, having its origin at the point and tangent, may be
taken as the envelope of a circle of constant radius having its
centre on the given curve. We have in like manner, as
derivatives of a given curve, the caustic, catacaustic or diacaustic
as the case may be, and the secondary caustic, or curve cutting
at right angles the reflected or refracted rays.

10. Forms of Real Curves.—We have in much that precedes
disregarded, or at least been indifferent to, reality; it is only thus
that the conception of a curve of the \( m \)-th order, as one which
is met by every right line in \( m \) points, is arrived at; and the curve
itself, and the line which cuts it, although both are tacitly
assumed to be real, may perfectly well be imaginary. For
real figures we have the general theorem that imaginary inter-
sections, &c., present themselves in conjugate pairs; hence, in
particular, that a curve of an even order is met by a line in an
even number (which may be \( m \)) of points; a curve of an odd
order in an odd number of points, hence in one point at least;
it will be seen further on that the theorem may be generalized in
a remarkable manner. Again, when there is in question only
one pair of points or lines, these, if coincident, must be real; but
thus, a line meets a cubic curve in three points, one of them
real, and other two real or imaginary; but if two of the inter-
sections coincide they must be real, and we have a line cutting
a cubic in one real point and touching it in another real point.
It may be remarked that this is a limit separating the two cases
where the intersections are all real, and where they are one real,
two imaginary.

Considering always real curves, we obtain the notion of a
branch; any portion capable of description by the continuous
motion of a point is a branch; and a curve consists of one or
more branches. Thus the curve of the first order or right line
consists of one branch; but in curves of the second order, or
conics, the ellipse and the parabola consist each of one branch, the
hyperbola of two branches. A branch is either re-entrant, if it extends both ways to infinity, and in this case, we may regard
it as consisting of two legs (crura, Newton), each extending one
way to infinity, but without any definite separation. The branch,
whether re-entrant or infinite, may have a cusp or cusps, or it may
cut itself or another branch, thus having or giving rise to crunodes
or double points with distinct real tangents; an acnode, or
double point with imaginary tangents, is a branch by itself,—
it may be considered as an indefinitely small re-entrant branch.
A branch may have inflections and double tangents, or there
may be double tangents which touch two distinct branches;
there are also double tangents with imaginary points of contact,
which are thus lines having no visible connexion with the curve.
A re-entrant branch not cutting itself may be everywhere
convex, and it is then properly said to be an oval; but the term
oval may be used more generally for any re-entrant branch not
cutting itself; and we may thus speak of a once indented, twice
indented oval, &c., or even of a cuspidate oval. Other descriptive
names for ovals and re-entrant branches cutting themselves
may be used when the case arises. In the last mentioned case
the simple form is that of a figure of eight; such a form may break
up into two ovals or into a doubly indented oval or hour-glass.
A form which presents itself when two ovals, one inside the
other, unite, so as to give rise to a crunode—in default of a better
name this may be called, after the curve of that name, a limaçon
(g.s.). Names may also be used for the different forms of infinite
branches, but we have first to consider the distinction of hyper-
bolic and parabolic. The leg of an infinite branch may have at
the extremity a tangent; this is an asymptote of the curve,
and the leg is then hyperbolic; or the leg may tend to a fixed
direction, but so that the tangent goes further and further off
to infinity, and the leg is then parabolic; a branch may thus
be hyperbolic or parabolic as to its two legs; or it may be hyper-
bolic as to one leg and parabolic as to the other. The
epithets
hyperbolic and parabolic are of course derived from the conic
hyperbola and parabola respectively. The nature of the two
kinds of branches is best understood by considering them as
projections, in the same way as we in effect consider the hyperbola
and the parabola as projections of the ellipse. If a line \( \ell \)
cuts the given curve in \( a, b, c \), so that \( a < b < c \) and \( \ell \) is not
tangential to the curve at \( a, b, c \); then projecting the figure
along the line \( \ell \), we see that the line \( \ell \) goes off into
infinity, the tangent at \( b \) is projected into the asymptote,
and the arc \( ab \) is projected into a hyperbolic leg touching the
asymptote at one extremity; the arc \( ba' \) will at the same time
be projected into a hyperbolic leg touching the same asymptote
at the other extremity (and on the opposite side), but so that
the two hyperbolic legs may or may not belong to one and the
same branch. And we thus see that the two hyperbolic legs belong
to a simple intersection of the curve by the line infinity. Next,
if the line \( \ell \) touch at \( b \) the arc \( aa' \) so that the two portions
\( ab, ba' \) lie on the same side of the line \( \ell \), then projecting the
figure as before, the tangent at \( b \), that is, the line \( \ell \) itself,
is projected to infinity; the arc \( ab \) is projected into a parabolic
leg, and at the same time the arc \( ba' \) is projected into a parabolic
leg, having at infinity the same direction as the other leg, but so
that the two legs may or may not belong to the same branch.
And we thus see that the two parabolic legs represent a contact
of the line infinity with the curve,—the point of contact being
the apex of one and the vertex of the other branch, the
asymptote of which is the line \( \ell \). It is evident that two
slightly different cases arise, one when the point of contact
is external to the curve, and another when it is internal; in
either case the two branches of a cusp (or cune) will be
hyperbolic, or parabolic, or both. The forms of these
asymptotes will be further described in a separate article.

The two legs of a hyperbolic branch may belong to different
asymptotes, and in this case we have the forms which Newton
CURVE

calls inscribed, circumscribed, ambigene, &c.; or they may belong to the same asymptote, and in this case we have the serpentine form, where the branch cuts the asymptote, so as to touch it at its two extremities on opposite sides, or the conchoidal form, where it touches the asymptote on the same side. The two legs of a parabolic branch may converge to ultimate parallelism, as in the conic parabola, or diverge to ultimate parallelism, as in the semi-cubical parabola \( y^2 = x \), and the branch is said to be convergent, or divergent, accordingly; or they may tend to parallelism in opposite senses, as in the cubical parabola \( y^3 = x^2 \). As mentioned with regard to a branch generally, an infinite branch of any kind may have cusps, or, by cutting itself or another branch, may have or give rise to a cusp, &c.

11. Classification of Cubic Curves.—We may now consider the various forms of cubic curves as appearing by Newton's Enumeratio, and by the figures belonging thereto. The species are reckoned as 72, which are numbered accordingly 1 to 72; but to these should be added 10, 13, 28 and 29. It is not intended here to consider the division into species, nor even completely that into genera, but only to explain the principle of classification. It may be remarked generally that there are at most three infinite branches, and that there may besides a re-entrant branch or oval.

The genera may be arranged as follows:—

- 1, 2, 3, 4 redundant hyperbolas
- 5, 6 defective hyperbolas
- 7, 8 parabolic hyperbolas
- 10 hyperbolisms, and hyperbola
- 11, 12 ellipse
- 13 parabola
- 12 trident curve
- 13 divergent parabolas
- 14 cubic parabola

and thus arranged they correspond to the different relations of the line infinity to the curve. First, if the three intersections by the line infinity are all distinct, we have the hyperbolas; if the points are real, the redundant hyperbolas, with three hyperbolic branches; but if only one of them is real, the defective hyperbolas, with one hyperbolic branch. Secondly, if two of the intersections coincide, say if the line infinity meets the curve in a onefold point and a twofold point, both of them real, then there is always one asymptote: the line infinity may at the twofold point touch the curve, and we have the parabolic hyperbolas; or the twofold point may be a singular point,—viz., a cusp giving the hyperbolisms of the hyperbola; an acnode, giving the hyperbolisms of the ellipse; or a cusp, giving the hyperbolisms of the parabola. As regards the so-called hyperbolisms, observe that (besides the single asymptote) we have in the case of those of the hyperbola two parallel asymptotes; in the case of those of the ellipse the two parallel asymptotes become imaginary, that is, they disappear; and in the case of those of the parabola they become coincident, that is, there is here an ordinary asymptote, and a special asymptote answering to a cusp at infinity. Thirdly, the three intersections by the line infinity are coincident, and if so we have a threefold point: this may be an inflection, a cusp, or a cusp. If the line infinity may be a tangent at an inflection, and we have the divergent parabolas; a tangent at a cusp to one branch, and we have the trident curve; or lastly, a tangent at a cusp, and we have the cubical parabola.

It is to be remarked that the classification mixes together non-singular and singular curves, in fact, the five kinds presently referred to: thus the hyperbolas and the divergent parabolas include curves of every kind, the separation being made in the species; the hyperbolisms of the hyperbola and ellipse, and the trident curve, are nodal; the hyperbolisms of the parabola, and the cubical parabola, are cuspidal. The divergent parabolas are of five species which respectively belong to and determine the five kinds of cubic curves; Newton gives (in two short paragraphs without any development) the remarkable theorem that the five divergent parabolas by their shadows generate and exhibit all the cubic curves.

The five divergent parabolas are curves each of them symmetrical with regard to an axis. There are two non-singular kinds, the one with, the other without, an oval, but each of them has an infinite (as Newton describes it) *cuspiform* branch; this cuts the axis at right angles, being at first concave, but ultimately convex, towards the axis, the two legs continually tending to become at right angles to the axis. The oval may unite itself with the infinite branch, or it may dwindle into a point, and we have the crunodal and the acnodal forms respectively; or if simultaneously the oval dwindles into a point and unites itself to the infinite branch, we have the cuspidal form. (See PARABOLA.) Drawing a line to cut any one of these curves and projecting the line to infinity, it would not be difficult to show how the line should be drawn in order to obtain a curve of any given species. We have herein a better principle of classification; considering cubic curves, in the first instance, according to singularities, the curves are non-singular, nodal (viz. crunodal or acnodal), or cuspidal; and we see further that there are two kinds of non-singular curves, the complex and the simplex. There is thus a complete division into the five kinds, the complex, simplex, crunodal, acnodal and cuspidal. Each singular kind presents itself as a limit separating two kinds of inferior singularity; the cuspidal separates the crunodal and the acnodal, and these last separate from each other the complex and the simplex.

The whole question is discussed very fully and ably by A. F. Möbius in the memoir "Über die Grundformen der Linien dritter Ordnung" (Abh. der K. Sachs. Ges. zu Leipzig, t. i., 1852). The author considers not only plane curves, but also cones, or, what is almost the same thing, the spherical curves which are their sections by a concentric sphere. Stated in regard to the cone, we have there the fundamental theorem that there are two different kinds of sheets; viz., the single sheet, not separated into two parts by the vertex (an instance is afforded by the plane considered as a cone of the first order generated by the motion of a line about a point, and the double or twin-pair sheet, separated into two parts by the vertex (as in the cone of the second order). And it then appears that there are two kinds of non-singular cubic cones, viz., the simplex, consisting of a twin sheet, and the complex, consisting of a single sheet and a twin-pair sheet; and we hence obtain (as for cubic curves) the crunodal, the acnodal and the cuspidal kinds of cubic cones.

It may be mentioned that the single sheet is a sort of wavy form, having upon it three lines of inflection, and which is met by any plane through the vertex in one or in three lines; the twin-pair sheet has no lines of inflection, and resembles in its form a cone on an oval base.

In general a cone consists of one or more single or twin-pair sheets, and if we consider the section of the cone by a plane, the curve consists of one or more complete branches, or say circuits, each of them the section of one sheet of the cone; thus, a cone of the second order is one twin-pair sheet, and any section of it is one circuit composed, it may be, of two branches. But although we thus arrive by projection at the notion of a circuit, it is not necessary to go out of the plane, and we may (with Zeuthen, using the shorter term circuit for his complete branch) define a circuit as any portion (of a curve) capable of description by the continuous motion of a point. It being understood that a passage through infinity is permitted. And we then say that a curve consists of one or more circuits; thus the right line, or curve of the first order, consists of one circuit; a curve of the second order consists of one circuit; a cubic curve consists of one circuit or else of two circuits.

A circuit is met by any right line always in an even number, or always in an odd number, of points, and it is said to be an even circuit or an odd circuit accordingly; the right line is an odd circuit, the conic an even circuit. And we have then the theorem, two odd circuits intersect in an odd number of points; an odd and an even circuit, or two even circuits, in an even number of points. An even circuit not cutting itself divides the plane into two parts, the one called the internal part, incapable of containing any odd circuit, the other called the external part, capable of containing an odd circuit.
We may now state in a more convenient form the fundamental distinction of the kinds of cubic curve. A non-singular cubic is simplex, consisting of one odd circuit, or it is complex, consisting of one odd circuit and one even circuit. It may be added that there are on the odd circuit three inflections, but on the even circuit no inflection; it hence also appears that from any point of the odd circuit there can be drawn to the odd circuit two tangents, and to the even circuit (if any) two tangents, but that from a point of the even circuit there cannot be drawn (either to the odd or the even circuit) any real tangent; consequently, in a simplex curve the number of tangents from any point is two; but in a complex curve the number is four, or none,—four if the point is on the odd circuit, none if it is on the even circuit. It at once appears from inspection of the figure of a non-singular cubic curve, which is the odd and which the even circuit. The singular kinds arise as before; in the crunoal and the cuspidal kinds the whole curve is an odd circuit, but in an acnodal kind the acnode must be regarded as an even circuit.

12. Quartic Curves.—The analogous question of the classification of quartics (in particular non-singular quartics and nodal quartics) is considered in Zeuthen's memoir "Sur les différentes formes des courbes planes du quatrième ordre" (Math. Ann. t. vii., 1874). A non-singular quartic has only even circuits; it has at most four circuits external to each other, two circuits of one kind, the internal circuit has no double tangents or inflections. A very remarkable theorem is established as to the double tangents of such a quartic: distinguishing as a double tangent of the first kind a real double tangent which either twice touches the same circuit, or else touches the curve in two imaginary points, the number of the double tangents of the first kind of a non-singular quartic is = 4; it follows that the quartic has at most 8 real inflections. The forms of the non-singular quartics are very numerous, but it is not necessary to go further into the question.

We may consider in relation to a curve, not only the line infinity, but also the circular points at infinity; assuming the curve to be real, these present themselves always conjointly; thus a circle is a conic passing through the two circular points, and is thereby distinguished from other conics. Similarly a cubic through the two circular points is termed a circular cubic; a quartic through the two points is termed a circular quartic, and if it passes twice through each of them, that is, has each of them for a node, it is termed a bicircular quartic. Such a quartic is of course binodal (m = 4, δ = 2, κ = 2); it has not in general, but it may have, a third node or cusp, having a curve giving a cusp at each of the circular points: such a curve is a "Cartesian," it being a complete definition of the Cartesian to say that it is a bicuspoidal quartic (m = 4, δ = 0, κ = 2), having a cusp at each of the circular points. The circular cubic and the bicircular quartic, together with the Cartesian (being in one point of view a particular case thereof), are interesting curves which have been much studied, generally, and in reference to their focal properties.

13. Foci.—The points called foci presented themselves in the theory of the conic, and were well known to the Greek geometers, but the general notion of a focus was first established by Plücker (in the memoir "Ueber solche Punkte die bei Curven einer höheren Ordnung den Brennpunkten der Kegelschnitte entsprechen" (Crelle, t. xii., 1833). We may from each of the circular points draw tangents to a given curve; the intersection of two such tangents (belonging of course to the two circular points respectively) is a focus. There will be from each circular point \( \lambda \) tangents (\( \lambda \), a number depending on the class of the curve and its relation to the line infinity and the circular points, 2 for the general conic, 1 for the parabola, 0 for a circular cubic, 2 for a bicircular quartic), \( \lambda \) tangents from the one circular point and those from the other circular point intersect in \( \lambda \) real foci (viz. each of these is the only real point on each of the tangents through it), and in \( \lambda^2 - \lambda \) imaginary foci; each pair of real foci determines a pair of imaginary foci (the so-called antipoints of the two real foci), and the \( \frac{1}{2}(\lambda^2 - \lambda - 1) \) pairs of real foci thus determine the \( \lambda^2 - \lambda \) imaginary foci. There are in some cases points termed centres, or singular or multiple foci (the nomenclature is unsettled), which are the intersections of improper tangents from the two circular points respectively; thus, in the circular cubic, the tangents to the curve at the two circular points respectively (or two imaginary asymptotes of the curve) meet in a centre.

14. Distance and Angle. Curves described mechanically.—The notions of distance and of lines at right angles are connected with the circular points; and almost every construction of a curve by means of lines of a determinate length, or at right angles to each other, and (as such) mechanical constructions by means of linkwork, give rise to curves passing the same definite number of times through the two circular points respectively, or say to circular curves, and in which the fixed centres of the construction present themselves as ordinary, or as singular, foci. Thus the general curve of three bar-motion (or locus of the vertex of a triangle, the other two vertices whereto move on fixed circles) is a tricircular sextic, having besides three nodes (\( m = 6, \delta = 3^2 + 3^2 + 3^2 = 27 \)), and having the centres of the fixed circles each for a singular focus; there is a third singular focus, and we have thus the remarkable theorem (due to S. Roberts) of the triple generation of the curve by means of the three several pairs of singular foci.

The normal, qua line at right angles to the tangent, is connected with the circular points, and these accordingly present themselves in the before-mentioned theories of evolutes and parallel curves.

15. Theories of Correspondence.—We have several recent theories which depend on the notion of correspondence: two points whether in the same plane or in different planes, or on the same curve in different curves, may determine each other in such wise that to any given position of the first point there correspond \( \alpha \) positions of the second point, and to any given position of the second point \( \alpha \) positions of the first point; the two points have then an \((\alpha, \alpha)\) correspondence; and if \( \alpha = \alpha \), the two points have a \((1,1)\) or rational correspondence. Connecting with each theory the author's name, the theories in question are G. F. B. Riemann, the rational transformation of a plane curve; Luigi Cremona, the rational transformation of a plane; and Crelle's, correspondence of points on the same curve, and united points. The theory first referred to, with the resulting notion of "Geschlecht," or deficiency, is more than the other two an essential part of the theory of curves, but that will all be considered.

Rational correspondences are contained in the memoirs on "Abelian Integrals," &c. (Crelle, t. liv., 1857), and we have next R. F. A. Clebsch, "Über die Singularitäten algebraischer Curven" (Crelle, t. xxv., 1866), and Cayley, "On the Transformation of Plane Curves" (Proc. Lond. Math. Soc. t. i., 1865; Collected Works, vol. vi. p. 1). The fundamental notion of the rational transformation is as follows:

Taking \( x, y, z \) to be rational and integral functions (\( X, Y, Z \) all of the same order) of the co-ordinates \( (x, y, z) \), and \( x', Y', Z' \) rational and integral functions (\( X', Y', Z' \), all of the same order) of the co-ordinates \( (x', y', z') \), the solutions of the equations (1) by the equations of \( x' \): \( y' = x'Z - Y'Z \), viz. assuming that this is the point \( (x, y, z) \) on the curve \( u = 0 \) will be points having a \((1,1)\) correspondence. To show how this is, observe that to a given point \( (x, y, z) \) on the curve \( u = 0 \) there corresponds a single point \( (x', y', z') \) determined by the equations \( x' \), \( y' = x'Z - Y'Z \) of \( x' \), \( y' \), \( z' \) not on the curve \( u' = 0 \) corresponds not a single point, but the system of points \( (x, y, z) \) given by the equations \( y' = x'Z - Y'Z \), \( x' \), \( y' \), \( z' \) as constants (and to fix the ideas, assuming that the curves \( X = Y = Z = 0 \) have no common points for the sections); these are the points of intersection of the curves \( X = Y = Z = 0 \), \( x' = y' = z' \), but no one of these points is situated on the curve \( u = 0 \). If, however, the point \( (x', y', z') \) is situated on the curve \( u = 0 \), then one point of the system of points in question is situated on the curve \( u = 0 \), that is, to a given point of the curve \( u = 0 \) there corresponds a single point of the curve \( u = 0 \); and hence also this point must be given by a system of equations such as \( x' = y' = z' = 0 \).

It is an old and easily proved theorem that, for a curve of
THE CURVE

the order \( m \), the number \( \delta + k \) of nodes and cusps is at most
\[ \frac{1}{2} (m - 1) (m - 2) \]; for a given curve the deficiency of the actual number of nodes and cusps below this maximum number, viz. 
\[ \delta + k \], is called the "Geschlecht" or "deficiency," of the curve, say this is \( \delta = D \). When \( \delta = 0 \), the curve is said to be
unicursal, when \( \delta = 1 \), bicursal, and so on.

The general theorem is that two curves corresponding rationally
to each other have the same deficiency. [In particular a
curve and its reciprocal have this rational or (1, 1) correspondence,
and it has been already seen that a curve and its reciprocal
have the same deficiency.] A curve of a given order can in general be rationally
transformed into a curve of a lower order; thus a curve of any order
for which \( \delta = 0 \), is a unicursal curve, can be transformed
into a line; a curve of any order having the deficiency 1 or 2
can be rationally transformed into a curve of the order \( D + 3 \),
deficiency \( D \); and a curve of any order deficiency of \( \geq 3 \)
can be rationally transformed into a curve of the order \( D + 3 \),
deficiency \( D \).

Taking \( x', y' \) as co-ordinates of a point of the transformed curve,
and in its equation writing \( x' : y' : z' = 1 : \theta : \phi \); if we have \( \phi \) a certain irrational
function of \( \theta \), of the order \( m \), the co-ordinates of any point of the given curve can be expressed as proportional
to rational and integral functions of \( \delta, \theta, \phi \), that is, of \( \theta \) and a certain
irrational function of \( \phi \).

It is clear if that, if the given curve be unicursal, the transformed
curve is a line, \( \phi \) is a mere linear function of \( \theta \), and the
theorem is that the co-ordinates \( x, y, z \) of a point of the unicursal
curve can be expressed as proportional to rational and integral functions of \( \theta \). It is easy to see that for a given curve of the order \( m \), these functions of \( \theta \) must be of the same order \( m \).

If \( \delta = 1 \), then the transformed curve is a cubic; it can be shown
that in a cubic, the axes of co-ordinates being properly chosen, \( \phi \) can be expressed as the square root of a cubic function of \( \theta \); and the theorem is that the co-ordinates \( x, y, z \) of a point of the bicursal
curve can be expressed as proportional to rational and integral functions of \( \theta, \phi \), and of the square root of a quartic function of \( \theta \). If \( \delta = 2 \) the transformed curve is a quartic; \( \phi \) can be expressed as the square root of a sextic function of \( \theta \); and
the theorem is, that the co-ordinates \( x, y, z \) of a point of the tricursal
curve can be expressed as proportional to rational and integral functions
of \( \theta, \phi \), and of the square root of an octic function of \( \theta \). But
\( \delta = 3 \), we have no longer the like law, viz. \( \phi \) is not expressible
as the square root of an octic function of \( \theta \).

Observe that the radical, square root of a quartic function,
is connected with the theory of elliptic functions, and the radical,
square root of a sextic function, with that of the first kind of
Abelian functions, but that the next kind of Abelian functions
does not depend on the radical, square root of an octic function.

It is a form of the theorem for the case \( \delta = 1 \), that the co-
ordinates \( x, y, z \) of a point of the bicursal curve, or in particular the co-ordinates of a point of the cubic, can be expressed as proportional
to rational and integral functions of the elliptic functions \( \eta, \epsilon, \delta \); in fact, taking the radical to be
\[ \sqrt{1 - \varphi^2 - \varphi^2 \eta} \], and writing \( \varphi = \eta \), the radical becomes
\[ \sqrt{\epsilon} \eta \delta \epsilon \delta ; \] and we have expressions of the form in question.

It will be observed that the equations \( x' : y' : z' = X : Y : Z \),
before mentioned, are not of themselves lead to the other system
of equations \( x : y : z = X' : Y' : Z' \); while, as before, \( X, Y, Z \)
de note rational and integral functions of the same co-ordinates,
and \( X', Y', Z' \) rational and integral functions, of all
of the same order, of the co-ordinates \( x', y', z' \), and there is thus a
(1, 1) correspondence given by these equations between the two
curves \( (x, y, z) \) and \( (x', y', z') \). We may observe further,
that from the equations for \( x, y, z \) we may have
\[ x = X', y = Y', z = Z' \]; to a given point \( (x, y, z) \) there corresponds
one point \( (x', y', z') \), but if \( n \) be the order of the functions \( X, Y, Z \), then to a given point \( x', y', z' \) there would, if
the curves \( X = 0, Y = 0, Z = 0 \) had no common intersections, correspond
\( n^2 \) points \( (x, y, z) \). If, however, the functions are such that
the curves \( X = 0, Y = 0, Z = 0 \) have \( k \) common intersections,
then among the \( n^2 \) points are included these \( k \) points, which are fixed
points independent of the point \( (x', y', z') \); so that, disregarding
these fixed points, the number of points \( (x, y, z) \) corresponding
to the given points \( (x', y', z') \) is \( n^2 - k \); and in particular if \( k = n^2 - 1 \),
then we have one corresponding point; and hence the original system of equations \( x = X', y = Y', z = Z' \); and in this system by the like reasoning
the functions must be such that the curves \( X = 0, Y = 0, Z = 0 \) have
\( n^2 - 1 \) common intersections. The most simple example is
in the two systems of equations \( x = x', y = y', z = z' \), and \( x = x', y = y', z = z' \)
(pairs of lines) having three common intersections, and where obviously either
system of equations leads to the other system. In the case where
\( X, Y, Z \) are of an order exceeding 2 the required number \( n^2 - 1 \) of common
intersections can only occur between the triple points on the three curves; and assuming that the curves \( X = 0, Y = 0, Z = 0 \) have
\( n^2 - 1 \) common intersections, where the \( e \) points are ordinary points, the \( s \) points are double points, the \( t \) points are triple points, &c., on each curve, we have the condition
\[ a_1 + a_2 + a_3 + \ldots + (s - 1) a_s = n^2 - 1 ; \]
but to this must be joined the condition
\[ a_1 + a_2 + a_3 + \ldots + (n - 1) a_{n-1} = (n + 3) - 2 \]
(without which the transformation would be illusory); and the conclusion is that \( a_1, a_2, \ldots, a_n \) may be any numbers satisfying these two equations. It may be added that the two equations together give
\[ a_1 + a_2 + \ldots + (n - 1) a_{n-1} = (n + 3) - 2 \]
which expresses that the curves \( X = 0, Y = 0, Z = 0 \) are unicursal.
The transformation may be applied to any curve \( \alpha = 0 \), which is
thus rationally transformed into a curve \( \alpha' = 0 \), by a rational trans-
formation such as is considered in Riemann's theory; hence the two
curves have the same deficiency.

Coming next to Hasles, the principle of correspondence is
established and used by him in a series of memoirs relating to the
conics which satisfy given conditions, and to other geometrical
questions, contained in the Completes rendus, t. viii. (1864) et seq.
The theorem of united points in regard to points in a right line
was given in a paper, June-July 1864, and it was extended to
divisor of the same series (March, 1866). "Sur quelques courbes planes ou à double courbure dont les points peuvent
se déterminer individuellement—application du principe de correspondance dans la théorie de ces courbes."

The theorem is as follows: if in a unicursal curve two points
have an \( (a, b) \) correspondence, then the number of united
points (or points each corresponding to itself) is \( a + b \). In fact in
an unicursal curve the co-ordinates of a point are given as proportional
to rational and integral functions of a parameter, and that any point
is defined by giving a particular value of the parameter; that is,
to each point of the curve corresponds one value of the parameter,
and to each value of the parameter one point on the curve; and
the \( (a, b) \) correspondence between the two points is given
by the fact that the co-ordinates \( x, y, z \) of the curve at two
points \( P' \) and \( P'' \), arising from the same parameter \( \theta \) and \( \phi \),
are pairs of points corresponding to each according to distinct laws;
then if \( (P', P'') \) are points having an \( (a, b) \) correspondence
in two united points, \( (P', P'') \) points having a \( (b, a) \) correspondence
with a number \( b \) of united points, and so on, the theorem is that
we have
\[ p(a - b) + g(b - c) + \ldots = 2 b D \]

The principle of correspondence, or say rather the theorem
of united points, is a most powerful instrument of investigation,
which may be used in place of analysis for the determination
of the number of solutions of almost every geometrical problem.
We can by means of it investigate the class of a curve, number
of inflections, &c.;—in fact, Plucker's equations; but it is necessary
to take account of special solutions: thus, in one of the most
simple instances, in finding the class of a curve, the cusps present
themselves as special solutions.

Imagine a curve of order \( m \), deficiency \( D \), and let the corresponding
points \( P, P' \) be such that the line joining them passes through a given

The elementary problems in regard to cubics are solved very completely by S. Maillard in his Thèse, Recherches des caractéristiques des systèmes éleméntaires des courbes planes du troisième ordre (Paris, 1871). Thus, considering the several cases of a cubic curve.

The point Q; this is an \((m-1, m-1)\) correspondence, and the value of \(k\) is\(=1\), hence the number of united points is \(=2m-2+2D\); the united points are the points of contact of the tangents from O and (as special solutions) the cusps, and we have thus the relation \(n+1=(m-1)(m-2)-3-k\), this is \(n=m(m-1)-2\theta-3k\), which is right.

The principle in its original form as applying to a right line was used throughout by Chasles in the investigations on the number of the conics which satisfy given conditions, and on the number of solutions of very many other geometrical problems.

There is one application of the theory of the \((a, a')\) correspondence between two planes which it is proper to notice.

Imagine a curve, real or imaginary, represented by an equation (involving, it may be, imaginary coefficients) between the Cartesian co-ordinates \(u, u')\), then, writing \(u=x+iy, u'=x'+iy\), the equation determines two pairs of \((x, y)\) and \((x', y')\) values of \((x, y)\), and \((x', y')\), corresponding to any given real values of \((x, y)\) and \((x', y')\) respectively; that is, it establishes a real correspondence (not of course a rational one) between the points \((x, y)\) and \((x', y')\); for example in the imaginary circle \(x^2+y^2=a^2\), the correspondence \((x, y)\) and \((x', y')\) is given by the equations \(x^2-y^2-x'y-y'^2=a^2\), or \(xy-x'y'=ab\). We have thus a means of geometrical representation for the portions, as well imaginary as real, of any real or imaginary curve. Considerations such as these have been used for determining the series of values of the independent variable \(t\), and the irrational functions thereof in the theory of Abelian integrals, but the theory seems to be worthy of further investigation.

16. Systems of Curves satisfying Conditions.—The researches of Chasles (Comptes Rendus, t. vii., 1864, et seq.) refer to the conics which satisfy given conditions. There is an earlier paper by J. P. E. Fauque de Jonquières, "Théorèmes généraux concernant les courbes géométriques planes d’un ordre quelconque," Liouw. t. vi. (1861), which establishes the notation of a system of curves (or any order of the index \(N\), viz. considering the curves of the order \(n\) which satisfy \(S(n+3)-1\) conditions, then the index \(N\) is the number of these curves which pass through a given arbitrary point. But Chasles in the first of his papers (February 1864), considering the conics which satisfy four conditions, establishes the notation of the two characteristics \((\mu, \nu)\) of such a system of conics, viz. \(\mu\) is the number of the conics which pass through a given arbitrary point, and \(\nu\) is the number of the conics which touch a given arbitrary line. And he gives the theorem, a system of conics satisfying four conditions, and having the characteristics \((\mu, \nu)\) contains \(\nu-\mu\) line-pairs (that is, conics, each of them a pair of lines), and \(2\nu-\nu\) point-pairs (that is, conics, each of them a pair of points,—coniques inimitable aptitudes), which is a fundamental one in the theory. The characteristics of the system can be determined when it is known how many there are of these two kinds of degenerate conics in the system, and how often each is to be counted. It was thus that Zeuthen (in the paper Nyt Bydrag, "Contribution to the Theory of Systems of Conics which satisfy Four Conditions") (Copenhagen, 1865), translated with an addition in the Nouvelles Annales solved the question of finding the characteristics of the systems of conics which satisfy four conditions of contact with a given curve or curves; and this led to the solution of the further problem of finding the number of the conics which satisfy five conditions of contact with a given curve or curves (Cayley, Comptes Rendus, t. ixii., 1865; Collecte Works, vol. v. p. 542), and finally of a general curve of which satisfy given Conics." (Phil. Trans. t. clvii., 1868; Collected Works, vol. vi. p. 191).

It may be remarked that although, as a process of investigation, it is very convenient to seek for the characteristics of a system of conics satisfying 4 conditions, yet what is really determined is in every case the number of the conics which satisfy 5 conditions; the characteristics of the system \((4p)\) of the conics which pass through 4 points are \((5p)\), \((4p, 1)\), the number of the conics which pass through 5 points, and which pass through 4 points and touch 1 line: and so in other cases. Similarly as regards cubics, or curves of any other order: a cubic depends on 9 constants, and the elementary problems are to find the number of the cubics \((9p)\), \((8p, 1)\), &c., which pass through 9 points, pass through 8 points and touch 1 line, &c.; but it is in the investigation convenient to seek for the characteristics of the systems of cubics \((8p)\), &c., which satisfy 8 instead of 9 conditions.
limit the proper tangents to $P_1 = 0$ each $a_i$ times, the lines to its nodes each $2a_i$ times, and the lines to its cusps each $3a_i$ times; the remaining terms $(a^2 - a_0)m_1 + (a^2 - a_0)m_2 + \ldots$ indicate tangents which are in the limit the lines drawn to the several summits, that is, we have $(a^2 - a_0)m$ summits on the curve $P_1 = 0$, $\& c.$.

There is, of course, a precisely similar theory as regards line-co-ordinates; taking $\Pi_1, \Pi_2, \& c.$, to be rational and integral functions of the co-ordinates ($x, y$) we connect with the ultimate curve $P_{n} = 0$, a line, and assume it, as the moment for the moment may be called "axes" tangents to the component curves $\Pi_1 = 0, \Pi_2 = 0$ respectively. Considering an equation in point-co-ordinates, we may have among the component curves right lines, and if in order to put these in evidence we take the equation to be $P_1 = 0, P_2 = 0, \& c.$, where $P_1 = 0$ is the line of the second or any other order, then the curve will contain as part of itself summits not exhibited in this equation, but the corresponding line-equation will be $\Pi_1 = 0, \Pi_2 = 0, \& c.$, the equations of the summits in question, $\Pi_1 = 0, \& c.$, are the line-equations corresponding to the several point-equations $P_1 = 0, \& c.$, and this curve will contain as part of itself axes not exhibited by this equation, but which are the lines $L_1 = 0, \ldots$ of the equation in point-co-ordinates.

18. Twisted Curves.—In conclusion a little may be said as to curves of double curvature, otherwise twisted curves or curves in space. The analytical theory by Cartesian co-ordinates was first considered by Alexis Claude Clairaut, *Recherches sur les courbes à double courbure* (Paris, 1731). Such a curve may be considered as described by a point, moving in a line which at the same time rotates about the point in a plane which at the same time rotates about the line; the point is a point, the line a tangent, and the plane an oscillating plane, of the curve; moreover the line having its own plane, and a plane tangent plane, of a developable surface or torse, having for the curve its edge of regression. Analogous to the order and class of a plane curve we have the order, rank and class of the system (assumed to be a geometrical one), viz. if an arbitrary plane contains $m$ points, an arbitrary line meets $r$ lines, and an arbitrary point lies in $n$ planes, of the system, then $m, r, n$ are the order, rank and class respectively. The system has singularities, and there exist between $m, r, n$ and the numbers of the several singularities equations analogous to Plücker's equations for a plane curve.

It is a leading point in the theory that a curve in space cannot in general be represented by means of two equations $U = 0, V = 0$: the two equations represent surfaces, intersecting in a curve; but there are curves which are not the complete intersection of any two surfaces; thus we have the cubic in space, or skew cubic, which is the residual intersection of two quadric surfaces which have a line in common; the equations $U = 0, V = 0$ of the two quadric surfaces represent the cubic curve, not by itself, but together with the line.

**CURVILINEAR,—**in architecture, that which is formed by curved or flowing lines; the roofs over the domes and vaults of the Byzantine churches were generally curvilinear. The term is also given to the flowing tracery of the Decorated and the Flamboyant styles.

**CURWEN, HUGH** (d. 1568), English ecclesiastical and statesman, was a native of Westmorland, and was educated at Cambridge, afterwards taking orders in the church. In May 1533 he expressed approval of Henry VIII's marriage with Anne Boleyn in a sermon preached before the king. In 1541 he became dean of Hereford, and in 1555 Queen Mary nominated him to the archbishopric of Dublin, and in the same year he was appointed lord chancellor of Ireland. He acted as one of the lords justices during the absence from Ireland of the lord deputy, the earl of Sussex, in 1557. On the accession of Elizabeth, Curwen at once accommodated himself to the new conditions by declaring himself a Protestant, and was continued in the office of lord chancellor. He was accosted by the Archbishop of Armagh on serious moral delinquency, and his recall was demanded both by the primate and the bishop of Meath. In 1557 Curwen resigned the see of Dublin and the office of lord chancellor, and was appointed bishop of Oxford. He died on the 1st of November 1568.

**CURWEN, JOHN** (1816–1880), English Nonconformist minister and founder of the Tonic Sol-Fa system of musical teaching, was born at Heckmondwike, Yorkshire, of an old Cumberland family. His father was a Nonconformist minister, and he himself adopted this profession, which he practised till 1804, when he gave it up in order to devote himself to his new method of musical nomenclature, designed to avoid the use of the stave with its lines and spaces. He adapted it from that of Miss Sarah Ann Glover (1785–1867) of Norwich, whose Sol-Fa system was based on the ancient gamut; but she omitted the constant recital of the alphabetical names of each note and the arbitrary syllable indicating key-relations, and also the recital of two or more such syllables when the same note was common to as many keys (e.g. "C, Fa, Ut," meaning that C is the subdominant of G and the tonic of C). The notes were represented by the initials of the seven syllables, still in use in Italy and France as their names; but in the "Tonic Sol-Fa" the seven letters refer to key-relationship and not to pitch. Curwen seems to have felt the importance of a simple way of teaching how to sing by note by his experiences among Sunday-school teachers. Apart from Miss Glover, the same idea had been elaborated in France since J. J. Rousseau's time, by Pierre Galin (1786–1821), Aimé Paris (1798–1866) and Emile Chevé (1804–1864), whose method of teaching how to read at sight also depended on the principle of "tonic relationship" being inculcated by the reference of every sound to its tonic, by the use of a numeral notation. Curwen brought out his *Grammar of Vocal Music* in 1843, and in 1853 started the Tonic Sol-Fa Association; and in 1859, after some difficulties with the education department the Tonic Sol-Fa College was opened. Curwen also took to publishing, and brought out a periodical called the *Tonic Sol-Fa Review*; and in his later life was occupied in directing the spreading organization of his system. He died at Manchester on the 26th of May 1886. His son John Spencer Curwen (b. 1847), who became principal of the Tonic Sol-Fa College, published *Memoirs of J. Curwen* in 1882. The Sol-Fa system has been widely adopted for use in education, as an easily teachable method in the reading of music at sight, but its more ambitious aims, which are strenuously pursued, for providing a superior method of musical notation generally, have not recommended themselves to musicians at large.

**CURZOLA** (Serbo-Croatian *Korcula* or *Korkar*), an island in the Adriatic Sea, forming part of Dalmatia, Austria; and lying west of the Salincello promontory, from which it is divided by a strait less than 2 m. wide. Its length is about 25 m.; its average breadth, 4 m. Curzola (*Korcula*), the capital and
principal port, is a fortified town on the east coast, and occupies a rocky foreland almost surrounded by the sea. Besides the
intentional church (formerly a cathedral), dating from the 12th
or 13th century, the lagoa or council chambers, and the palace
of its former Venetian governors, it possesses the noble mansion
of the Arneri, and other specimens of the domestic architecture
of the 15th and 16th centuries, together with the massive walls
and towers, erected in 1420, and the 15th-century Franciscan
monastery, with its beautiful Venetian Gothic cloister. The
main resources of the islanders are boat-building (for which they are celebrated throughout the Adriatic), fishing and sea-
where, the cultivation of the vine, corn and olives, and breeding
of mules. Pop. (1900) of island, 17,377; of capital (town and
commune), 6,486. Prehistoric grave-mounds are common on
the hills of the interior, and in later times Curzola may have
been a Phoenician settlement. Its early history is very obscure,
but it was certainly colonized by Greeks from Cnidus. The
present name is a corruption of the Gr. Κόμωρα Μδιναρ, or
Lat. Corcyræa Niga, “Black Corcyra”; and is perhaps due
to the dark pines which still partly cover the island. In
998 Cutillo, 6th master, when Venetian pirates entered a
fifth century it was ruled by Hungary and Genoa in turn, and
enjoyed a brief period of independence; but after 1255 its hereditary
counts again submitted to Venice. The Roman Catholic Church of
Curzola, created in 1301, was only suppressed in 1806. Curzola
surrendered to the Hungarians in 1358, was purchased by Rugusa
(1413-1417), and finally declared itself subject to Venice in 1420.
In 1571 it defended itself so gallantly against the Turks that
it obtained the designation fidelissima. From 1776 to 1797 it
succeeded Lefka as the main Venetian arsenal in this region.
During the Napoleonic wars it was ruled successively by Russians,
French and British, ultimately passing to Austria in 1815.

CURZON OF KEDLESTON, GEORGE NATHANIEL, 1ST
BArON (1839- ), English statesman, eldest son of the 4th
baron Scarsdale, rector of Kedleston, Derbyshire, was born on
the 11th of January 1839, and was educated at Eton and Balliol
College, Oxford. At Oxford he was president of the Union,
and after a brilliant university career was elected a fellow of All Souls
College in 1863. After his admission he removed to Lord
Salisbury in 1883, and in 1886 entered parliament as member
for the Southport division of S.W. Lancashire. He was appointed
under secretary for India in 1891-1892 and for foreign affairs
in 1895-1898. In the meantime he had travelled in Central Asia,
Persia, Afghanistan, the Pamirs, Siam, Indo-China and Korea,
and published several books describing central and eastern Asia
and the political problems connected with those regions. In 1895
he married Mary Victoria Leiter (d. 1906), daughter of a Chicago
millionaire. In January 1899 he was appointed governor-
general of India, where his extensive knowledge of Asiatic affairs
showed itself in the inception of a strong foreign policy, while he
took in hand the reform of every department of Indian admin-
istration. He was created an Irish peer on his appointment,
the creation taking this form, it was understood, in order that
he might remain free during his father’s lifetime to re-enter the
House of Commons. Reaching India shortly after the sup-
pression of the frontier risings of 1897-98, he paid special
attention to the defence of the north-west frontier, in which
inaugurated a new province called the North West Frontier
Province, and carried out a policy of conciliation mingled with
firmness of control. The only trouble on this frontier during the
period of his administration was the Mahsud Waziri campaign
of 1901. Being distrustful of Russian methods he exerted
himself to encourage British trade in Persia, paying a visit to
the Persian Gulf in 1903; while on the north-east frontier he
anticipated a possible Russian advance by the Tibet Mission of
1903, which rendered necessary the employment of military force
for the protection of the British envos. The mission, which had
the ostensible support of China as suzerain of Tibet, penetrated
to Lhasa, where a treaty was signed in September 1904. In
pursuance of his reforming policy Lord Curzon appointed a
number of commissions to inquire into Indian education, irrigation,
police and other branches of administration, on whose
reports legislation was based during his second term of office as
viceroy. With a view to improving British relations with the
native chiefs and raising the character of their rule, he estab-
lished the Imperial Cadet corps, settled the question of Berar with
the nizam of Hyderabad, reduced the salt tax, and gave relief to
the smaller income-tax payers. Lord Curzon exhibited much
interest in the art and antiquities of India, and during his
viceroyalty took steps for the preservation and restoration of
many important monuments and buildings of historic interest.
In January 1903 he presided at the durbar held at Delhi in honour
of the coronation of King Edward VII. It was attended by all
the leading native princes and by large numbers of visitors from
Europe and America; and the magnificence of the spectacle
surpassed anything that had previously been witnessed even in
the gorgeous ceremonial of the East. On the expiration of his
first term of office, Lord Curzon was reappointed governor-
general. His second term of office was marked by the passing
of several acts founded on the recommendations of his previous
commission, and by the partition of Bengal (1905), which roused
bitter opposition amongst the natives of that province. A differ-
ce of opinion with the Indian minister of the interior, Lord
Kitchener, regarding the position of the military minister in
India, led to a controversy in which Lord Curzon failed to obtain
support from the home government. He resigned (1904) and
returned to England. In 1904 he was appointed lord warden of
the Cinque Ports; in the same year he was given the honorary
degree of D.C.L. by Oxford University, and in 1908 he was
elected chancellor of the university. In the latter year he was
elected a representative peer for Ireland, and thus relinquished
any idea of returning to the House of Commons. In 1909-1910
he took an active part in defending the House of Lords against
the Liberals. Lord Curzon’s publications include Russia in
Central Asia (1889); Persia and the Persian Question (1892);
See Caldwell Lipsett, Lord Curzon in India, 1859-1909 (1906); and

CUSANUS, NICHOLAS (NICHOLAS OF CUSA) (1401-1464),
cardinal, theologian and scholar, was the son of a poor fisherman
named Kyprianus of Cusus, and Cusiana, by whom he is
known from the place of his birth, Kues or Cusa, on the Moselle,
in the archbishopric of Trier (Treves). In his youth he was
employed in the service of Count Ulrich of Manderscheid, who,
seeing in him evidence of exceptional ability, sent him to study
at the school of the Brothers of the Common Life at Deventer,
and afterwards at the university of Padua, where he took his
doctor’s degree in law in his twenty-third year. Failing in his
first case he abandoned the legal profession, and resolved to
take holy orders. After filling several subordinate offices he
became archdeacon of Liège. He was a member of the council
of Basel, and dedicated to the assembled fathers a work entitled
De concordantia Catholica, in which he maintained the superiority
of councils over popes, and assailed the genuineness of the False
Decretals and the Donation of Constantine. A few years later,
however, he had reversed his position, and zealously defended
the supremacy of the pope. He was entrusted with various missions
in the interests of Catholic unity, the most important being
to Constantinople, to undertake a new crusade against the
Eastern and Western churches. From 1440 to 1447 he was
in Germany, acting as papal legate at the diets of 1441, 1442, 1445
and 1446. In 1448, in recognition of his services, Nicholas V.
raised him to the cardinalate; and in 1450 he was appointed
bishop of Brixen against the wish of Sigismund, archduke of
Austria, who opposed the reforms the new bishop sought to
introduce into the diocese. In 1451 he was sent to Germany and
the Netherlands to check ecclesiastical abuses and bring back
the monastic life to the original rule of poverty, chastity and
obedience—a mission which he discharged with well-
tempered firmness. Soon afterwards his dispute with the arch-
duke Sigismund in his own diocese was brought to a point by his
claiming certain dues of the bishopric, which the temporal prince
had appropriated. Upon this the bishop was imprisoned by the
archduke, who, in his turn, was excommunicated by the pope.
These extreme measures were not persisted in; but the dispute remained unsettled at the time of the bishop's death, which occurred at Rome in 1864. In 1455 he had acted as governor of Rome during the absence of the able and learned Pope Pius II. at the assembly of princes at Milan; and he wrote his Crebroto Alcoroni, a treatise against Mahomedanism, in support of the expedition against the Turks proposed at that assembly. Some time before his death he had founded a hospital in his native place for thirty-three poor persons, the number being that of the years of the earthly life of Christ. To this institution he left his valuable library.

Although one of the great leaders in the reform movement of the 15th century, Nicholas of Cusa's interest for later times lies in his philosophic much more than in his political or ecclesiastical activity. As in religion he is entitled to be called one of the "Reformers before the Reformation," so in philosophy he was one of those who broke with scholasticism while it was still the orthodox system. In his principal work, De docta ignorantia (1440), supplemented by De conjunctis libri duo published in the same year, he maintains that all human knowledge is mere conjecture, and that man's wisdom is to recognize his ignorance. From scepticism he escapes by accepting the doctrine of the mystics, that God is the at last secret (speculatio), an exalted state of the intellect in which all limitations disappear. God is the absolute maximum and the absolute minimum, who can be neither greater nor less than He is, and who comprehends all that is or that can be ("deum esse omnia, ut non possit esse aliud quam est"). Cusanus thus laid himself open to the charge of pantheism, which did not fail to be brought against him in his own day. His chief philosophical doctrine was taken up and developed more than a hundred years later by Giordano Bruno, who calls him the divine Cusanus. In mathematical and physical science Cusanus was much in advance of his age. In a tract, Reparatio Calendarii, presented to the council of Basel, he proposed the reform of the calendar after a method resembling that adopted by Gregory. In his De Quadratura Circuli he professed to have solved the problem; and in his Conjecturae de maximis et minibus he prophesied that the world would come to an end in 1734. Most noteworthy, however, in this connexion is the fact that he anticipated Copernicus by maintaining the theory of the rotation of the earth.

The Cusanus, and the Copernicus, was published in the 16th century by Henrich Petri (1 vol., Basel, 1565). See also F. A. CUSH, the eldest son of Ham, in the Bible, from whom we have derived the name of the "Land of Cush," commonly rendered "Ethiopia" by the Septuagint and by the Vulgate. The locality of the land of Cush has long been a much vexed question. Bochart maintained that it was exclusively in Arabia; Schultes and Gesenius held that it should be sought for nowhere but in Africa (see ETHIOPIA). Others again, like Michaelis and Rosenmüller, have supposed that the name Cush was applied to tracts of country both in Arabia and in Africa, but the defective condition of the ancient knowledge of countries and peoples, as also the probability of early migrations of "Cushite" tribes (carrying with them their name), will account for the main facts. The existence of an African Cush cannot reasonably be questioned, though the term is derived from the Old Testament with some latitude. The African Cush covers Upper Egypt, and extends southwards from the first cataract (Syene, Ezek. xxix. 10). That the term was also applied to parts of Arabia is evident from Gen. x. 7, where Cush is the "father" of certain tribal and geographical names, all of which point very clearly to Arabia, with the very doubtful exception of Seba, which Josephus (Ant. ii. 10. 2) identifies with Meroë. Even in the 5th century a.d. the Himyarites, in the south of Arabia, were styled by Syrian writers Cusheans and Ethiopians. Moreover, the Babylonian inscriptions mention the Kasshish, an Elamite race, whose name has been equated with the classical Koovrat, Kiarus, and it has been held that this affords a more appropriate explanation of Cush (perhaps rather Kashi), the ancestor of (the Babylonian) Nimrod in Gen. x. 8. Although decisive evidence is lacking, it seems extremely probable that several references to Cush in the Old Testament cannot refer to Ethiopia, despite the likelihood that considerable confusion existed in the minds of early writers. The Cushite invasion in 2 Chron. xiv. (see ASA) is intelligible if the historical foundation for the story be a raid by Aramaeans, but in v. 8 the inclusion of Libyans shows that the enemy was subsequently supposed to be African. In several passages the interpretation is bound up with that of Mizraim (q.v.), and depends in general upon the question whether Ethiopia at a given time enjoyed the prominence given to it.

CUSHING, Caleb (1800-1879), American political leader and lawyer, was born in Salisbury, Massachusetts, on the 17th of January 1800. He graduated at Harvard in 1821, was tutor in mathematics there in 1820-1821, was admitted to practice in the court of common pleas in December 1821, and began the practice of law in Newburyport, Mass., in 1824. After serving, as a Democratic-Republican, in the state house of representatives in 1825, in the state senate in 1826, and in the house again in 1828, he spent two years, from 1829 to 1831, in Europe, again served in the state house of representatives in 1833 and 1834, and in the latter year was elected by the Whigs a representative in Congress. He served in this body from 1835 until 1843, and here the marked inconsistency which characterized his public life became manifest; for when John Tyler had become president, he had been "read out" of the Whig party, and had vetoed Whig measures (including a tariff bill), for which Cushing had voted. Cushing first defended the votes and then voted against the president. In 1843, President Tyler nominated him for secretary of the treasury, but the senate refused to confirm him for this office. He was, however, appointed later in the same year commissioners of the United States to China, holding this position until 1845, and in 1844 negotiating the first treaty between China and the United States. In 1847, while again a representative in the state legislature, he introduced a bill appropriating money for the equipment of a regiment to serve in the Mexican War; although the bill was defeated, he raised the necessary funds privately, and served in Mexico first as colonel and afterwards as brigadier-general of volunteers. In 1847 and again in 1848 the Democrats nominated him for governor of Massachusetts, but on each occasion he was defeated at the polls. He was again a representative in the state legislature in 1851, became an associate justice of the supreme court of Massachusetts in 1852, and during the administration (1853-1857) of President Pierce, was attorney-general of the United States. In 1853, 1859, 1862 and 1863 he again served in the state house of representatives. In 1866 he presided over the National Democratic Convention which met in Charleston and was later in Baltimore, until he joined those who seceded from the regular convention; he then presided also over the convention of the seceding delegates, who nominated John C. Breckinridge for the presidency. During the Civil War, however, he supported the National Administration. At the Geneva conference for the settlement of the "Alabama" claims in 1871-1872 he was one of the counsel for the United States.

1 For Seba, see SABÆANS, and cf. generally the commentaries on Gen. x. 7. In Hab. iii. 7 Cushan (obviously a related form) is parallel to Midian.
CUSHING, W. B.—CUSTARD APPLE

In 1873 President Grant nominated him for chief justice of the United States, but in spite of his great learning and eminence at the bar, his ante-war record and the feeling of distrust experienced by many members of the senate on account of his inconsistency, aroused such vigorous opposition that his nomination was soon withdrawn. From 1874 to 1877 Cushing was United States minister to Spain. He died at Newburyport, Mass., on the 2nd of January 1879. He published History and Present State of the Town of Newburyport, Mass. (1826); Review of the late Revolution in France (1833); Reminiscences of Spain (1833); Oration on the Growth and Territorial Progress of the United States (1839); Life and Public Services of William H. Harrison (1840); and The Treaty of Washington (1873).

CUSHING, WILLIAM BARKER (1842–1874), American naval officer, was born in Delafield, Wisconsin, on the 4th of November 1842. He entered the Naval Academy in 1857, but resigned in March 1861. When, however, the Civil War began, he volunteered into the navy, was rated acting master's mate, and became a midshipman in October 1861, and a lieutenant in July 1862, serving in the North Atlantic blockading squadron. The work of blockade, and of harassing the Confederates on the coast and the rivers of the Atlantic seaboard, called for much service in boats, and entailed a great deal of exposure. Cushing was distinguished by his readiness to volunteer, his indefatigability, and by his good fortune, the reward of vigilance and intelligence. The feat by which he will be remembered was the destruction of the Confederate ironclad "Alamere" in the Roanoke river on the 27th of October in 1864. The vessel had done much damage to the Federal naval forces, and her destruction was greatly desired. She was at anchor surrounded by baulks of timber, and a cordon of boats had been stationed to row guard against an expected Federal attack. Lieutenant Cushing undertook the attack on her with a steam-launch carrying a spar-torpedo and towing an armed cutter. He eluded the Confederate lookout and reached the "Alamere" unseen. When close to he was detected, but he had time to drive the steam launch over the baulks and to explode the torpedo against the "Alamere" with such success that a hole was made in her and she sank. Cushing's own launch was destroyed. He and the few men with him were compelled to take to the water; one was killed, another was drowned, Cushing and one other escaped, and the rest were captured. Cushing himself swam to the swamps on the river bank, and after wading among them for hours reached a Federal picket boat. For destroying the "Alamere" he was thanked by Congress and was promoted to be lieutenant-commander. On the 15th of January 1865 he took a conspicuous part in the land attack on the sea-front wall of Fort Fisher. After the war he commanded the "Lancaster" (1866–1867) and the "Maumee" (1868–1869) in the Asiatic Squadron. In 1872 he was promoted commander at what was an exceptionally early age, but he died on the 17th of December 1874 of brain fever. He had suffered extreme pain for years before his death, and in fact broke down altogether under disease contracted in the discharge of his duty.

CUSHION (from O. Fr. coisson, coussin; according to the New English Dict., from Lat. cœsa, a hip; others say from Lat. cœcla, a quilt), a soft bag of some ornamental material, stuffed with wool, hair, feathers, or even paper torn into fragments. It may be used for sitting or kneeling upon, or to soften the hardness or angularity of a chair or couch. It is a very ancient article of furniture, the inventories of the contents of palaces and great houses in the middle ages constantly making mention of it. It was then often of great size, covered with leather, and firm enough to serve as a seat, but the steady tendency of all furniture has been to grow smaller. It was, indeed, used as a seat, at all events in France and Spain, at a very much later period, and in Saint-Simon's time we find that at the Spanish court it was still regarded as a peculiarly honourable substitute for a chair. In France the right to kneel upon a cushion in church behind the king was jealously guarded and strictly regulated, as we may learn again from Saint-Simon. This type of cushion was called a carreau or square. When seats were rude and hard the cushion may have been a necessity; it is now one of the minor luxuries of life.

The term "cushion" is given in architecture to the sides of the Ionic capital. It is also applied to an early and simple form of the Romanesque capitals of Germany and England, which consist of cubical masses, square at the top and rounded off at the four corners, so as to reduce the lower diameter to a circle of the same size as the shaft.

CUSHMAN, CHARLOTTE SAUNDERS (1816–1876), American actress, was born in Boston, Massachusetts, on the 23rd of July 1816. Her father, a West India merchant, left his family in straitened circumstances, and Charlotte, who had a fine control of voice, went on the operatic stage. In 1835 she successfully appeared at the Tremont theatre as the countess Almaviva in The Marriage of Figaro. But her singing voice failing her she entered the drama, and played Lady Macbeth in the same year. She then engaged herself as a stock actress, but was soon given leading parts. In 1842 she managed and played in the Walnut Street theatre in Philadelphia. She accompanied Macready on an American tour, winning a great reputation in tragedy, and in 1845 and in 1854–1855 she fulfilled successful engagements in London. She was a keen student, and acquired a large range of classic roles. Her best parts were perhaps Lady Macbeth and Queen Katherine, her most popular Meg Merrilies, in a dramatization of Scott's Guy Monnering. Her figure was commanding and her face expressive, and she was animated by a temperament full of vigour and fire. These qualities enabled her to play with success such male parts as Romeo and Cardinal Wolsey. During her later years Miss Cushman worked hard as a dramatic reader, in which capacity she was much appreciated. Her last appearance on the stage took place on the 15th of May 1875, at the Globe theatre, Boston, in which city she died on the 18th of February 1876.

See Emma Stebbins's Charlotte Cushman, her Letters and Memories of her Life (Boston, 1878); H. A. Clapp's Reminiscences of a Dramatic Critic (Boston, 1902); and W. T. Price, A Life of Charlotte Cushman (New York, 1894).

CUSP (Lat. cuspis, a spear, point), a projecting point, or pointed end. In architecture (Fr. feuille, Ital. cuspid, Ger. Knopf), a cusp is the point where the foliations of tracery intersect. The earliest example of a plain cusp is probably that at Pythagoras school, at Cambridge,—of an ornamented cusp at Ely cathedral, where a small roll, with a rosette at the end, is formed by the termination of a cusp. In the later styles the terminations of the cusps were more richly decorated; they also sometimes terminate not only in leaves or foliages, but in rosettes, heads and other fanciful ornaments. The term "feathering" is used of the junction of the foliated cusps in window tracery, but is usually restricted to those cases where it is ornamented with foliage, &c.

CUSTARD APPLE, a name applied to the fruit of various species of the genus Anona, natural order Anonaceae. The members of this genus are shrubs or small trees having alternate, exstipulate leaves, and flowers with three small sepalas, six petals arranged in a double row and numerous stamens. The fruit of A. reticulata, the common custard apple, or "bullock's heart" of the West Indies, is dark brown in colour, and marked with depressions, which give it a quilted appearance; its pulp is reddish-yellow, sweetish and very soft (whence the name); the kernels of the seeds are said to be poisonous. The sour-sop is the fruit of A. maritica, native of the West Indies. The plant, which is a small tree, has become naturalized in some parts of India where it is extensively cultivated, as elsewhere in the tropics. It is covered with soft prickles, is of a light-greenish hue, and has a peculiar but agreeable sour taste, and a scent resembling that of black currants. The sweet-sop is produced by A. sphaeros, also a native of the West Indies and widely cultivated.

1 The term "custard," now given to a dish made with eggs beaten up with milk, &c., and either served in liquid form or baked to a custard or pudding, originally referred to a kind of sweetmeat. It comes from the old form "cruaste," Fr. croûstade, Ital. crostate, from croste, to accrust.
in the tropics. It is known as the custard apple by Europeans in India. It is an egg-shaped fruit, with a thick rind and juicy pulp. An aerial principle, fatal to insects, is contained in its seeds, leaves and unripe fruits, which, powdered and mixed with the flour of gum (Cicer arietinum), are used to destroy vermin. A. Cherimolia yield the Peruvian cherimoyer, which is a fruit of very superior flavour, and is much esteemed by the creoles. A. palustris, alligator apple, or cork-wood, a native of South America and the West Indies, is valued for its wood, which serves the same purposes as cork; the fruit, commonly known as the alligator-apple, is not eaten, being reputed to contain a dangerous narcotic principle.

**CUSTER, GEORGE ARMSTRONG** (1839-1876), American cavalry soldier, was born in New Rumley, Harrison county, Ohio, on the 5th of December 1839. He graduated from West Point in 1861, and was at once sent to the theatre of war in Virginia, joining his regiment on the battlefield of Bull Run. Afterwards he served on the staff of General Kearny, and on that of General W. F. Smith in the Peninsular Campaign. His daring and energy, and in particular a spirited reconnaissance on the Chickahominy River, brought him to the notice of General McClellan, who made him an aide-de-camp on his own staff, with the rank of captain. A few hours afterwards Custer attacked a Confederate picket post and drove back the enemy. He continued to serve with McClellan until the general was relieved of his command, when Custer returned to duty with his regiment as a lieutenant. Early in 1863 General Pleasonton selected him as his aide-de-camp, and in June 1863 Custer was promoted to the rank of brigadier-general of volunteers. He distinguished himself at the head of the Michigan cavalry brigade in the battle of Gettysburg, and frequently did good service in the remaining operations of the campaign of 1863. When the cavalry corps of the Army of the Potomac was reorganized under Sheridan in 1864, Custer retained his command, and took part in the various actions of the cavalry in the Wilderness and Shenandoah campaigns. At the end of September 1864, he was appointed to command a division, and on the 9th of October fought, along with General Merritt, the brilliant cavalry action called the battle of Woodstock. Soon afterwards he was made brevet-major-general, U.S.V., having already won the brevets of major, lieutenant-colonel and colonel U.S.A., for his services at Gettysburg, Yellow Tavern and Winchester. In his part in the decisive battle of Cedar Creek (Oct. 19) was most conspicuous. He served with Sheridan in the last great cavalry raid, won the action of Waynesboro, and in the final campaign added to his laurels by his conduct at Dinwiddie and Five Forks, and in other operations. At the close of the war he received the brevets of brigadier and major-general in the regular army, and was promoted major-general of volunteers. In 1866 Custer was made lieutenant-colonel of the 7th U.S. Cavalry, and took part under General Hancock in the expedition against the Cheyenne Indians, upon whom he inflicted a crushing defeat at Washita river on the 27th of November 1868. In 1873 he was sent to Dakota Territory to serve against the Sioux. The 7th, to which Custer brought his regiment formed part, was made against the Sioux and their allies. As the advanced guard of the troops under General Terry, Custer's force arrived at the junction of Big Horn and Little Big Horn rivers, in what is now the state of Montana, on the night of June 24; the main body was due to join him on the 26th. Unfortunately, the presence of what was judged to be a small isolated force of Indians was reported to the general. On the 25th, dividing his regiment into three parties, he moved forward to surround this force. But instead of meeting only a small force of Indians, the 7th were promptly attacked by the full forces of the enemy. The flanking columns maintained themselves with difficulty until Terry came up. Custer and 264 men of the centre column rode into the midst of the enemy and were slaughtered to a man.

The general's wife, Elizabeth Bacon Custer, who accompanied him in many of his frontier expeditions, wrote *Boots and Saddles, Life with General Custer in Dakota* (1885), *Tenting on the Plains* (1887) and *Following the Guidon* (1891). General Custer himself wrote *My Life on the Plains* (1874).

His brother Thomas Ward Custer (1845-1876), in spite of his youth, fought in the early campaigns of the Civil War. Becoming aide-de-camp to General Custer, he accompanied him throughout the latter part of the war, distinguishing himself by his daring on all occasions, and winning successively the brevets of captain, major and lieutenant-colonel, though he was barely twenty years of age when the war ended. He was first lieutenant in the 7th cavalry when he fell with his brother at the Little Big Horn.

**CUSTINE, ADAM PHILIPPE, COMTE DE (1740-1793), French general, began his military career in the Seven Years' War. He next served with distinction against the English in the War of American Independence. In 1780 he was elected to the states-general by the *baillage* of Metz. In October 1791 he again joined the army, with the rank of lieutenant-general and became popular with the soldiers, amongst whom he was known as "gérald moustache." General-in-chief of the army of the Vosges, he took Spires, Worms, Mainz and Frankfort in September and October 1792. He carried on the revolutionary propaganda by proclamations, and levied heavy taxes on the nobility and clergy. During the winter a Prussian army forced him to evacuate Frankfort, re-cross the Rhine and fall back upon Landau. He was accused of treason, defended by Robespierre, and sent back to the army of the north. But he dared not take the offensive, and did nothing to save Condé, which the Austrians were besieging. Sent to Paris to justify himself, he was found guilty by the Revolutionary Tribunal of having intrigued with the enemies of the republic, and guillotined on the 28th of August 1793. (See French Revolutionary Wars.)

**CUSTINE (from O. Fr. custume, costume or custumex; Low Lat. custumix, a shortened form of custumex); or custume, a custom, that is, practice. Thus a tradesman calls those who deal with him his "customers," and the trade resulting as their "custom." The word is also used for a toll or tax levied upon goods; there was at one time a distinction between the tax on goods exported or imported, termed *magnum custumum* (the great custom), and that on goods taken to market within the realm, termed *parva custumum* (the little custom), but the word is now used in this sense only in the plural, to signify the duties levied upon imported goods. It is also used as a name for that department of the public service which is employed in levying the duty.

In law, such long-continued usage as has by common consent become a rule of conduct is termed custom. Jessel, M. R. (Hamerton v. Honey, 24 W. R. 603), has defined it as "local common law. It is common law because it is not statute law; it is local law because it is the law of a particular place, as distinguished from the general common law. Local common law is the law of the country (i.e. particular place) as it existed before the adoption of a Statute. It consists of such laws, rules and usages as, from generation to generation, have been recognized by the judges as the law of the community. There has been much discussion among jurists as to whether custom can properly be reckoned a source of law (see Jusprudential). As to the distinction between prescription (which is a personal claim) and custom, see Prescription. The adoption of local customs by the judiciary has undoubtedly been the origin of a great portion of the English common law. Blackstone divides custom into (1) general, which is the common law properly so called, and (2) particular, which affects only the inhabitants of particular districts. The requisites necessary to make a particular custom good are: (1) it must have been used so long that the memory of man runneth not to the contrary; (2) it must have been continued, and (3) enjoyed peaceably; (4) it must be reasonable, and (5) certain; (6) it must be compulsory, and not left to the option of every man whether he will use it or not; (7) it must be consistent with other customs, for one custom cannot be set up in opposition to another. Customs may be of various kinds, for example, customs of merchants, customs of a certain district
CUSTOMARY FREEHOLD—CUTC

1848, the Austrians commanded by Field-Marshall Radetzky being victorious over the Piedmontese army under King Charles Albert. The second battle was fought on the 24th of June 1860, and resulted in the complete victory of the Austrians under the archduke Albert, over the Italian army of King Victor Emmanuel I. (See ITALIAN WARS, 1848-1870.)

ČUSTRIN, or KÜSTRIN, a town of Germany, in the kingdom of Prussia, a fortress of the first rank, at the confluence of the Oder and Warthe, 18 m. N.E. from Frankfurt-on-Oder and 51 m. N.E. of Berlin by rail. Pop. (1900) 16,743 (including the garrison). It consists of the town proper within the strong fortifications, a suburb on the left bank of the Oder, and one on the right bank of the Warthe. There are three Evangelical churches and one Roman Catholic, and a handsome town hall. There are bridges over both rivers. Čustrin has some manufactories of potato-meal, machinery, pianos, furniture, cigars, &c., and there is a considerable river trade.

About 1250 a town was erected on the site of Čustrin, where a fishing village originally stood. From 1333 till 1371 it was the residence of John, margrave of Brandenburg-Čustrin, who died without male heirs in 1371. Čustrin was the prison of Frederick I. of Silesia. Great when crown-prince, and the scene of the execution of his friend Hans Hermann von Kätz on the 6th of November 1730.

CUTC, or KACH, a native state of India within the Gujarat division of Bombay, with an area of 7,016 sq. m. It is a peninsula tract of land, enclosed towards the W. by the eastern branch of the Indus, on the S. by the Indian Ocean and the Gulf of Cutch, and on the N. and E. towards the interior, by the great northern Rann, a salt morass or lake. The interior of Cutch is studded with hills of considerable elevation, and a range of mountains runs through it from east to west, many of them of the most fantastic shapes, with large isolated masses of rock scattered in all directions. The general appearance of Cutch is barren and uninteresting. The greater part is a rock desert, of soil, and presenting the wildest aspect; the ground is cold, poor and sterile; and the whole face of the country bears marks of volcanic action. From the violence of the wind, and the rapine of a disorderly banditti, by which this district long suffered, as well as from shocks of earthquakes, the villages have a ruinous and dilapidated appearance; and, with the exception of a few fields in the neighbourhood, the country presents a rocky and sandy waste, with in many places scarcely a show of vegetation. Water is scarce and brackish, and is chiefly found at the bottom of low ranges of hills, which abound in some parts; and the inhabitants of the extensive sandy tracts suffer greatly from the want of it. Owing to the uncertainty of the periodical rains in Cutch, the country is liable to severe famines, and it has suffered greatly from plague.

The temperature of Cutch during the hottest season is high, the thermometer frequently rising to 100° or 105° F.; and in the months of April and May clouds of dust and sand, blown about by hurricanes, envelop the houses, the glass windows scarcely affording any protection. The influence of the monsoon is greatly moderated before it reaches this region, and the rains sometimes fall altogether. Bhuj, the capital of the state, is situated inland, and is surrounded by an amphitheatre of hills, some of which approach within 3 or 4 m. of the city. The hill of Bhujia, on which the fort is situated, rises to the height of 500 ft. in the middle of the plain, and is detached from the other hills by a great gorge. The residency is 4 m. distant in a westerly direction. There are many mountain streams, but no navigable rivers. They contain scarcely any water except in the rainy season, when they are very full and rapid, and discharge themselves into the Rann, all along the coast of which the wells and springs are more or less impregnated with common salt and other saline ingredients.

Various causes have contributed to thin the population of this country. In 1813 it was ravaged by a famine and pestilence, which destroyed a great proportion of its inhabitants,—according to some accounts, nearly one-half. This, joined to the tyranny and violence of the government until the year 1819, and subsequently to a succession of unfavourable seasons, forced many...
of the cultivators to remove to Sind and other countries. The inhabitants numbered 486,022 in 1901, being a decrease of 13% during the decade, due to the famines of 1899-1900. One-third are Mahomedans and the remainder Hindus of various castes.

The Jareja Rajputs form a particular class, being the aristocracy of the country and all are more or less connected with the family of the rao or prince. There are in Cutch about 200 of these Jareja chiefs, who all claim their descent from a prince who reigned in Sind about 1000 years ago. From him also the reigning sovereign is lineally descended, and he is the liege lord of whom all the chiefs or nobles hold their lands in feu, for services which they or their ancestors had performed, or in virtue of their relationship to the family. They are all termed the brotherhood of the rao or Bhayad, and supposed to be his hereditary advisers, and their possessions are divided among their male children. To prevent the breaking down of their properties, the necessary consequence of this law of inheritance, there is no doubt that infanticide was common among them, and that it extended to the male as well as the female progeny; but it has been put down by the Infanticide Rules, which provide for the registration of Jareja children. The Jarejas have a trick of that when they adopt a Cutch they retain Mahomedan customs, but the they afterward adopted the customs and religion of the Hindus. It is certain, indeed, that they still retain many Mahomedan customs. They take oaths equally on the Koran or on the Shastras; they employ Mussulman books; they eat from their hands; the rao, when he appears in public, alternately worships God in a Hindu pagoda and a Mahomedan mosque; and he fits out annually at Mandvi a ship for the conveyance of pilgrims to Mecca, who are maintained during the voyage chiefly by the liberality of the prince. The Mahomedans in Cutch are of the same degenerate class as those usually found in the western parts of India. The natives are in general of a stronger and stouter make, and even handsomer, than those of western India; and the women of the higher classes are also handsome. The peasants are described as intelligent, and the artizans are justly celebrated for their ingenuity and mechanical skill. The palace at Mandvi, and a tomb of one of their princes at Bhuj, are fair specimens of their architectural skill. The estimated annual revenue is £126,322. There are special manufactures of silver filigree-work and embroidery. The maritime population supplies the best sailors in India. There are cotton presses and ginning factories.

The country of Cutch was invaded about the 13th century by a body of Mahomedans of the Summa tribe, who under the guidance of five brothers emigrated from Sind, and who gradually subdued or expelled the original inhabitants, consisting of three distinct races. Cutch continued tranquil under the sway for many years, until some family quarrel arose, in which the chief of an elder branch of the tribe was murdered by a rival brother. His son Khengayi fled to Ahmedabad to seek the assistance of the viceroy, who reinstated him in the sovereignty of Cutch, and Morvi in Kathiawar, and in the title of rao, about the year 1540. The succession continued in the same line from the time of this prince until 1607, when a younger brother, Pragji, murdered his elder brother and usurped the sovereignty. This line of princes continued till 1813, when the Mahomedans of Cutch, with the aid of the British, expelled the Mahomedans of the tribe, and the rao Ghodji, the country was invaded four times by the Sinds, who wasted it with fire and sword. The reign of this prince, as well as that of his son Rao Rayadan, by whom he was succeeded in 1728, was marked by cruelty and blood. The latter prince was dethroned, and, being in a state of mental derangement, was during his lifetime confined by Fateh Mahommed, a native of Sind, who continued, with a short interval (in which the party of the legal heir, Bhaiji Bawa, gained the ascendency), to rule the country until his death in 1813. It was in the reign of Fateh Mahommed that a communication first took place with the British government. During the contests for the sovereignty between the usurper and the legal heir, the leader of the royal party, Hansraj, the governor of Mandvi, sought the aid of the British. But no closer connexion followed at that time than an agreement for the suppression of piracy, or of inroads of troops to the eastward of the Runn or Gulf of Cutch. But the gulf continued notwithstanding to swarm with pirates, who were openly encouraged or connived at by the son of HUTCH, GULP, who had succeeded his father, as well as by Fateh Mahommed. The latter left several sons by different wives, who were competitors for the vacant throne. Husain Miyan succeeded to a considerable portion of his father's property and power. Jugjevan, a Brahman, the late minister of Fateh Mahommed, also received a considerable share of influence; and the hatred of these two factions was embittered by religious animosities, the one being Hindu and the other Mahomedan. The deceased rao had declared himself a Mahomedan, and his adherents were preparing to inter his body in a magnificent tomb, when the Jarejas and other Hindus seized the corpse and consigned it to the flames, according to Hindu custom.

The administration of affairs was nominally in the hands of Husain Miyan and his brother Ibrahim Miyan. Many sanguinary broils now ensued, in the course of which Jugjevan was murdered, and the executive authority was much weakened by the usurpations of the Arabs and other chiefs. In the meantime Ibrahim Miyan was assassinated; and after various other scenes of blood, the rao Bhumrulji, son of Rao Rayadan, by general consent, assumed the chief power. But his reign was one continued series of the grossest enormities; his hostility to the British became evident, and accordingly a force of 10,500 men crossed the Runn in November 1815, and were within five miles of Bhuj, the capital of the country, when a treaty was concluded, by which the rao Bhumrulji was confirmed in his title to the throne, on agreeing, among other stipulations, to cede Anjar and its dependencies in perpetuity to the British. He was, however, so far from fulfilling the terms of this treaty that it was determined to depose him; and an army being sent against him, he surrendered to the British, who made a provision for his maintenance, and elevated his infant son Desalji II. to the throne (1816).

In 1832 the relations subsisting between the ruler of Cutch and the British were modified by a new treaty, under which the territorial cessions made by the rao in 1816 were restored in consideration of an annual payment. The sum fixed was subsequently raised to £14,000, and in 1832 the arrears, amounting to a considerable sum, were remitted, and all future payments on this account relinquished. From that time the rao has paid a subsidy of £13,000 per annum to the British for the maintenance of the military force stationed within his dominions.

Rao Desalji II. did much to suppress infanticide, suttee and the slave trade in his state. His successor Maharoa Pragmalji in recognition of his excellent administration was in 1871 honoured with the title of knight grand commander of the Star of India. During his rule harbour works were built at Mandvi, an immense reservoir for rain water in the Chadhwa hills was constructed, and many schools and colleges were endowed. In 1876 he was succeeded by Maharao Rao Khengarji III., who was also a keen advocate for education and especially the education of women. He founded museums, libraries and schools, and inaugurated scholarships and a fund from which deserving scholars desirous of studying in England and America could obtain their expenses.

The Gulf of Cutch, or Rann of Kach, a salt morass on the western coast of India in the native state of Cutch. From May to October it is flooded with salt water and communicates, at its greatest extent, with the Gulf of Cutch on the west and the Gulf of Cambay on the east, these two guls being united during the monsoon. It varies in breadth from five to eighty miles across, and during the rains is nearly impassable for horsemen. The total area of this immense morass is estimated at about 8000 sq. m., without including any portion of the Gulf of Cutch, which is in parts so shallow as to resemble a marshy fen rather than an arm of the sea. The Runn is said to be formed by the overflow of the rivers Pharan, Luni, Banas and others, during the monsoon; but in December it is quite dry, and in most places hard, but in some moist and muddy. The soil is impregnated
with salt, and the Runn is an important source for the supply of salt. The present condition of the Runn is probably the result of some natural curvilinear, but the exact method of its formation is disputed. The wild ass is very common on the borders of this lake, being seen in herds of 60 or 70 together.

CUTHBERT, SAINT (d. 687), bishop of Lindisfarne, was probably a Northumbrian by birth. According to the extant Life he was led to take the monastic vows by a vision at the death of bishop Aidan. The date of his entry at Melrose was 631. At this time Eata was abbott there, and Boisil, who is mentioned as his instructor, prior, in which office Cuthbert succeeded him about 661, having previously spent some time at the monastery of Ripon with Eata. Bede gives a glowing picture of his missionary zeal at Melrose, but in 664 he was transferred to act as prior at Lindisfarne. In 676 he became an anchorite on the island of Farne, and it is said that he performed miracles there. In 684 at the council of Twyford in Northumberland, Ecgfrith, king of Northumbria, prevailed upon him to give up his solitary life and become a bishop. He was consecrated at York in the following year as bishop of Hexham, but afterwards he exchanged his see with Eata for that of Lindisfarne. In 687 he retired to Farne, and died in the island on March 20. Before his death he sent his friend Herebert, the anchorite of Derwentwater. He was buried in the island of Lindisfarne, but his remains were afterwards deposited at Chester-le-Street, and then at Durham.

Another Cuthbert was bishop of Hereford from 736 to about 740, and archbishop of Canterbury from the latter date until his death in October 758.

There are several lives of St Cuthbert, the best of which is the prose life by Bede, which is published in Bede's Opera, edited by J. Stevenson (1841). See also C. Eyre, The History of St Cuthbert (1889); and J. Rainie, St Cuthbert (1826).

CUTLASS, the naval side-arm, a short cutting sword with a slightly curved blade, and a solid basket-shaped guard (see SWORD). The word is derived from the Fr. coutelas or coutelace, a form of cutel, modern coutene, a knife, from Lat. cultellus, diminutive of culter, a ploughshare, or cutting instrument. Two variations appear in English: "cutelace," where the r represents probably the l of the original Latin word, or is a further variant of the second variation; and "cutel," often spelled as two words, "cutel," "cutel," where the prefix "cutel" is confused with various English words such as "cutane," "cutal," and "cutel," which all mean "shortened," and are derived from the Lat. curus; the word thus wrongly derived has been supposed to refer to some non-existent form of battle-axe. In every case the weapon to which these various forms apply is a broad cutting or slashing sword.

CUTLERY, MANASSEH (1742–1823), American clergyman, was born in Killingly, Connecticut, on the 13th of May 1742. He graduated at Yale College in 1765, and after being a school teacher and a merchant, and occasionally appearing in the courts as a lawyer, he decided to enter the ministry, and from 1771 until his death was pastor of the Congregational church at what is now Hamilton, but until 1793 was a parish of Ipswich, Massachusetts. During the War of Independence he was for several months in 1776 chaplain to the regiment of Colonel Ebenezer Francis, raised for the defence of Boston; and in 1778, as chaplain to the brigade of General Jonathan Pitcomb (1728–1817), he took part in General John Sullivan’s expedition to Rhode Island. Soon after his return from this expedition he fitted himself for the practice of medicine, in order to supplement the scanty income of a minister, and in 1782 he established a private boarding school, which he conducted for about a quarter of a century. In 1786 he became interested in the settlement of western lands, and in the following year, as agent of the Ohio Company (q.v.), which he had taken a prominent part in organizing, he made a contract with Congress, whereby his associates, former soldiers in the War of Independence, might purchase, with the certificates of indebtedness issued to them by the government for their services, 1,500,000 acres of land in the region north of the Ohio at the mouth of the Muskingum river. He also took a leading part in drafting the famous Ordinance of 1787 for the government of the Northwest Territory, the instrument as it was finally presented to Congress by Nathan Dane (1752–1835), a Massachusetts delegate, probably being largely Cutler’s work. From 1801 to 1805 he was a Federalist representative in Congress. He died at Hamilton, Massachusetts, on the 28th of July 1823. A versatile man, Cutler was one of the early members of the American Academy of Arts and Sciences, and besides being proficient in the theology, law and medicine of his day, conducted painstaking astronomical and meteorological investigations, and was one of the first Americans to make researches of a real scientific value in botany. In 1789 the degree of doctor of laws was conferred upon him by Yale.

See William P. and Julia P. Cutler, The Life, Journals, and Correspondence of Manasseh Cutler, 2 vols. (1868–1869), and an article, "The Ordinance of 1787 and Dr Manasseh Cutler," by W. F. Poole, in vol. 122 of the North American Review.

Cutlery (Fr. coutellerie, from the Lat. cultellus, a little knife), a branch of industry which originally embraced the manufacture of all cutting instruments of whatever form or material. The progress of manufacture of cutlery has, however, detached from it the fabrication of shears, scissors, and similar implements, the manufacture of which is now regarded as forming distinct branches of trade. On the other hand modern cutlery includes a great number of articles which are not strictly cutting instruments, but which, owing to their more or less intimate relation to table or pocket cutlery, are classed with such articles for convenience sake. A steel table or carving fork, for example, is an important article of cutlery, although it is not a cutting tool.

The original cutting instruments used by the human race consisted of fragments of flint, obsidian, or similar stones, rudely flaked or chipped to a cutting edge; and of these tools numerous remains yet exist. Stone knives and other tools must have been employed for a long period by the prehistoric races of mankind, as their later productions show great perfection of form and finish. In the Bronze period, which succeeded the Stone Age, the cutlery of our ancestors was fabricated of that alloy. The use of iron was introduced at a later but still remote period; and it now, in the form of steel, is the staple article from which cutlery is manufactured.

From the earliest period in English history the manufacture of cutlery has been peculiarly associated with the town of Sheffield, the prominence of which in this manufacture in his own age is attested by Chaucer, who says of the miller of Trumptington—

"A Sheffield wytel baar he in his hase."

That town still retains a practical monopoly of the ordinary cutlery trade of Great Britain, and remains the chief centre of the industry for the whole world. Its influence on methods of production has also been widely extended; for instance, many Sheffield workmen emigrated to the United States of America to take part in the manufacture of pocket-knives when it was started in Connecticut towards the middle of the 19th century.

The twitel or whistle of Chaucer’s time was a very poor rude implement, consisting of a blade of bar steel fastened into a wooden or horn handle. It was used for cutting food as well as for the numerous miscellaneous duties which now fall to the pocket-knife. To the whistle succeeded the Jack knife,—the Jacques de Lige, or Jock-te-jeg of the Scottish James VI.,—which formed the forerunner of the modern clasp-knife, inasmuch as the blade closed into a groove in the handle. About the beginning of the 17th century, the pocket-knife with spring back was introduced, and no marked improvement thereafter took place until the early part of the 19th century. In 1824, two centuries after the incorporation of the Cutlers’ Company of London, the cutlers of Hallamshire—the name of the district of which Sheffield is the centre—were formed into a body corporate for the protection of the “industrie, labour, and reputation” of the trade, which was being disgraced by the “deceitful and unworkmanlike wares of various persons.” The act of incorporation specifies the manufacture of “knives, scissors, shears, sickles and..."
other cutlery," and provides that all persons engaged in the business shall make the edge of all steel implements manufactured by them of steel, and steel only, and shall strike on theirwares such mark, and such only, as should be assigned to them by the officers of the said company." Notwithstanding these regulations, and the pains and penalties attached to their infringement, the corporation was not very successful in maintaining the high character of Sheffield wares. Most manufacturers made cutlery to the order of their customers, on which the name of the retailer was stamped, and very inferior malleable or cast iron blades went forth to the public with "London made," "best steel," and other falsehoods stamped on them to order. The corporate mark and name of a few firms, among which Joseph Rodgers & Sons stand foremost, are a guarantee of the very highest excellence of material and finish; and such firms decline to stamp any name or mark other than their own on their manufactures. In foreign markets, however, the reputation of such firms is much injured by impudent forgeries; and so far was this system of fraud carried that inferior foreign work was forwarded to London to be transshipped and sent abroad ostensibly as English cutlery. To protect the trade against frauds of this class the Trades Mark Act of 1862 was passed chiefly at the instigation of the Sheffield chamber of commerce. The variety of materials which go to complete the single article of blades, and (3) putting together the various parts, the whole list of a cutter embraces a vast number of articles different in form, properties and uses, the cutter manufacturer must have a practical knowledge of a wide range of substances. The leading articles of the trade include carving and table knives and forks, pocket or clasp knives, razors, scissors, daggers, hunting knives and similar articles, surgical knives and lancets, butchers' and shoemakers' knives, gardeners' pruning-knives, &c. The blades or cutting portions of a certain number of these articles are made of steel, and for others crucible cast steel is employed. Sometimes the cutting edge alone is of steel, backed or strengthened with iron, to which it is welded. The tang, or part of the blade by which it is fastened to the handles, and other non-cutting portions, are also very often of iron. Brass, German silver, silver, horn, tortoise-shell, ivory, bone, mother-of-pearl, and numerous fancy woods are all brought into requisition for handles and other parts of cutlery, each demanding special treatment according to its nature. The essential processes in making a piece of steel cutlery are (1) forging, (2) hardening and tempering, (3) grinding, (4) polishing, and (5) the making of the handle. The finished knife, the workmen who perform these last operations being the only ones known in the trade as "cutters." The following outline of the stages in the manufacture of a razor will serve to indicate the sequence of operations in making an article which, though simple in form, demands the highest care and skill. The first essential of a good razor is that it be made of the finest quality of cast steel. The steel for razors is obtained in bars the thickness of the back of the instrument. Taking such a bar, the forger heats one end of it to the proper forging temperature, and then dexterously fashions it upon his anvil, giving it roughly the required form, edge and concavity. It is then separated from the remainder of the bar, leaving only sufficient metal to form the tang, if that is to be made of steel. The tang of the "mould," as the blade in this condition is termed, is next drawn out, and the whole "smithed" or beaten on the anvil to compact the metal and improve the form and edge of the razor. At this stage the razor is said to be " forged in the rough," and so nimly can some workmen finish off this operation that a shaving edge may be given to the blade by simple whetting. The forged blade is next "shaped" by grinding on the dry stone; this operation considerably reduces its weight, and removes the oxidized scale, thereby allowing the hardening and tempering to be done with certainty and proper effect. The shaped razor is now returned to the forge, where the tang is file-cut and pierced with the joint-hole, and into the blade is stamped either the name and corporate mark of the maker, or any mark and name ordered by the tradesman for whom the goods are being manufactured. The hardening is accomplished by heating the blade to a cherry-red heat and suddenly quenching it in cold water, which leaves the metal excessively hard and brittle. To bring it to the proper temper for a razor, it is again heated till the metallic surface assumes a straw colour, and after being plunged into water, it is then treated for the process of wet grinding. The wet grinding is done on stones which vary in diameter from 1½ to 1½ in., according to the concavity of surface desired ("hollow-ground," "half hollow-ground," &c.). "Lapping," which is the first stage in polishing, is performed on a wheel of the same diameter as the wet-grinding stone. The lap is built up of segments of wood having the fibres towards the periphery, and covered with a metallic alloy of tin and lead. The lap is fed with a mixture of emery powder and oil. "Glazing" and "polishing," which follow, are for perfecting the polish on the surface of the razor, leather-covered wheels with fine emery being used; and the work is finished off with crocus. The finished blade is then riveted into the scales or handle, which may be of ivory, bone, horn or other material; and when thereafter the razor is set on a hone it is ready for use. The processes employed in making a table-knife do not differ essentially from those required for a razor. Table-knife blades are forged from steel and other steels, and, if they are not in one piece, a bit of malleable iron sufficient for the bolster or shoulder and tang is welded to them, often by machinery, and then finished in the finest manner. The bolster is formed with the aid of a die and is stamped, whilst the tang is drawn out. The tang is variously formed, according to the method by which it is to be secured in the haft, and the various processes of tempering, wet grinding and polishing are pursued as described above. Steel forks of an inferior quality are cast and subsequently cleaned and polished; but the best quality are forged from bar steel, and the prongs are cut or stamped out of an extended flattened extremity called the mould or "mood." In the United States of America machinery has been extensively adopted for performing the various mechanical operations in forging and fitting table cutlery, and in Sheffield it is employed to a great extent in the manufacture of table and pocket knife blades, scissors and razors. The cutter of the 18th century was an artisan who forged and ground the blades and fitted them in the hafts ready for sale; to-day the division of labour is carried to an extreme degree. In the making of a common pocket-knife with three blades not fewer than one hundred separate operations are involved, and these may be performed by as many workmen composed of five distinct classes—the scale and spring makers (the scale being the metal lining which is placed between the two blades proper), the blade forgers, the grinders, the cutters of the coverings of ivory, horn, &c., that form the handles, and the hafters or cutters proper. Grinders are divided into three classes—dry, wet and mixed grinders, according as they work at dry or wet stones. This branch of trade is, in Sheffield, conducted in distinct establishments called "wheels," which are divided up into separate apartments or "hulls," the dry grinding being as much as possible separated from the wet grinding. Dry grinding, such as is practised in the shaping of razors described above, the "humming" or rounding of scissors, and other operations, used to be a process especially dangerous to health, lung diseases being induced by the fine dust of silica and steel with which the atmosphere was loaded; but a great improvement has been effected by resorting to wet grinding as much as possible, by arranging fans to remove the dust by suction, and by general attention to sanitary conditions.

CUTTACK, a city and district of British India in the Orissa division of Bengal. The city is situated at the head of the delta of the Mahanadi. Pop. (1901) 51,364. It is the centre of the Orissa canal system, and an important station on the East Coast railway from Madras to Calcutta. It contains the government college, named after Mr. Ravenshaw, a former commissioner; a high school, a training school, a survey school, a medical school and a law school. The city formed one of the five royal strongholds of ancient Orissa and was founded by a warlike Hindu prince, Makar Kesari, who reigned from 953 to 961. Native kings protected it from the rivers by a masonry embankment several miles long, built of enormous blocks of hewn stone, and...
in some places 25 ft. high. A fortress defended the north-west corner of the town, and was captured by the English from the Maharrats in October 1803. It is now abandoned as a place of defence.

The District of Cuttack lies in the centre of Orissa, occupying the delta of the Mahanadi and Brahmani, together with a hilly tract inland. Its area is 36,545 sq. m. It consists of three physical divisions: first, a marshy woodland strip along the coast, from 3 to 30 m. in breadth; second, an intermediate stretch of rice plains; third, a broken hilly region, which forms the western boundary of the district. The marshy strip along the coast is covered with swamps and malaria-breeding jungles. Towards the sea the solid land gives place to a vast network of streams and creeks, whose sluggish waters are constantly depositing silt, and forming morasses or quicksands. Cultivation does not begin till the limits of this dismal region are passed. The intermediate rice plains stretch inland for about 40 m. and occupy the older part of the delta between the sea-coast strip and the hilly frontier. They are intersected by three large rivers, the Baitaran, Brahmani and Mahanadi. These issue in magnificent streams through three gorges in the frontier hills. The Cuttack delta is divided into two great valleys, one of them lying between the Baitaran and the Brahmani, the other between the Brahmani and the Mahanadi. The rivers having, by the silt of ages, gradually raised their beds, now run along high levels. During floods they pour over their banks upon the surrounding valleys, by a thousand channels which interlace and establish communication between the main streams. After numerous bifurcations they find their way into the sea by three principal mouths. Silt-banks and surf-washed bars render the entrance to these rivers perilous. The best harbour in Cuttack district is False Point, on the north of the Mahanadi estuary. It consists of an anchorage, land-locked by islands or sand-banks, and with two fair channels navigable towards the land. The famine commissioners in 1867 reported it to be the best harbour on the coast of India from the Hugli to Bombay.

The intermediate tract is a region of rich cultivation, dotted with great banyan trees, thickets of bamboo, exquisite palm foliage and mango groves. The hilly frontier separates the delta of British Orissa from the semi-independent tributary states. It consists of a series of ranges, 10 to 15 m. in length, running nearly due east and west, with densely-wooded slopes and lovely valleys between. The timber, however, is small, and is of little value except as fuel. The political character of these ranges is as distinct as are their natural features. The first and third are still occupied by feudal chiefs, and have been subjected to a regular land-settlement, by either the Mussulman or the British government. They pay a light fixed tribute. The intermediate rice plains, known as the Mogholbandi, from their having been regularly settled by the Mahomedans, have yielded to the successive dynasties and conquerors of Orissa almost the whole of the revenues derived from the province. The deltaic portions are of course a dead level, and the highest hills within the district in the western or frontier tract do not exceed 2300 ft. They are steep, and covered with jungle, but can be climbed by men. The most interesting of them are the Assa range, with its sandal trees and Buddhist remains; Udayagiri (Sunrise-hill), with its colossal image of Buddha, sacred reservoir, and ruins; and Assagiri, with its mosque of 1719. The Mahavinyaka peak, visible from Cuttack, has been consecrated for ages to Siva-worship by ascetics and pilgrims.

The population of the district in 1901 was 2,062,758, showing an increase of 6% in the preceding decade. The aboriginal tribes here, as elsewhere, cling to their mountains and jungles. They chiefly consist of the Bhumij, Tala, Kol and Savara peoples, the Savaras being by far the most numerous, numbering 14,775. They are regarded by the orthodox Hindus as little better than the beasts of the wildernesses which they inhabit. Miserably poor, they subsist for the most part by selling firewood or other products of their jungle; but a few of them have patches of cultivated land, and many earn wages as day labourers to the Hindus. They occupy, in fact, an intermediate stage of degradation between the comparatively well-to-do tribes in the tributary states (the stronghold and home of the race), and the Pans, Bauris, Kandras and other semi-aboriginal peoples on the lowlands, who rank as the basest castes of the Hindu community. The great bulk of the Indo-Aryan or Hindu population consists of Uriyas, with a residue of immigrant Bengalis, Lala Kayets from Behar and northern India, Telingas from the Madras coast, Maharrats from central and western India, a few Sikhs from the Jutjunab and Marwaris from Rajputana. The Mahomedans are chiefly the descendants of the Pathans who took refuge in Orissa after the subversion of their kingdom in Bengal by the Moguls in the 16th century.

Rice forms the staple product of the district; its three chief varieties are *bali* or early rice, *sorar* or winter rice, and *dalna* or spring rice. The other cereal crops consist of *mandu* (a grass-like plant producing a coarse grain resembling rice), wheat, barley, and *china*, a rice-like cereal. *Suan*, another rice-like cereal, not cultivated, grows spontaneously in the paddies. Pulses of different sorts, oilseeds, fibres, sugar-cane, tobacco, spices and vegetables also form crops of the district. The cultivators consist of two classes—the resident husbandmen (*thami*) and the non-resident or migratory husbandmen (*pohi*).

The Orissa canal system, which lies mainly within Cuttack district, is used both for irrigation and transport purposes. The railway across the district towards Calcutta, a branch of the Bengal-Nagpur system, was opened in 1899. Considerable trade is carried on at the mouth of the rivers along the coast.

**CUTTLE-FISH**. The more familiar and conspicuous types of the molluscan class Cephalopoda (q.v.) are popularly known in English as cuttle-fish, squid, octopus and nautilus. The first of these names (from the A.S. *cudele*) is applied more particularly to the common *Sepia* (fig. 1), characterized by its internal calcareous shell, sometimes known as cuttle-bone, and its ink-sac, the contents of which have been long in use as a pigment (*sepia*). The term squid is employed among fishermen for the ten-armed Cephalopods in which the shell is represented by an uncalled for flexible structure somewhat resembling a pen. Hence in Italian a squid is called *calamaio*, from *calama* a reed or pen, and in English the similar term *calamary* is sometimes used. Like the *Sepia*, squids also possess the ink-sac, whence they have sometimes been called pen and ink fish, and in German both *Sepia* and squid and their allies are known as Tinten-fische. The squids have generally softer and more watery tissues than the *Sepia*, but the former term is not in general use, and the distinction not generally understood. The term cuttle-fishes is sometimes employed to exclude all the Cephalopoda, but as the peculiarities of the remarkable shell of the true octopods and allless Octopodes are widely known, we shall consider the name here as applying only to those forms which have ten arms, an ink-sac, an internal shell-rudiment, and only one pair of gills in the mantle cavity. Technically these form the sub-order Decapoda, of the order Dibranchia.

The cuttle-fishes are characteristically swimming animals, in contrast with the octopods, which creep about by means of their suckers among the rocks, and lurk in holes. In *Sepia* the integument is produced laterally into two muscular fins, rather narrow and of uniform breadth running the whole length of the body, but separated by a notch behind. There are four pairs of short non-retractile arms surrounding the mouth, and furnished with suckers on their oral surface, and between the third and fourth of these arms on each side is a much longer tentacular arm, which is usually kept entirely withdrawn into a pocket of the skin. The mantle cavity is on the posterior side of the body, which is the lower side in the swimming position, and the funnel is a tube open at both ends and connected with the body within the mouth of the mantle cavity. The mantle during life performs regular respiratory movements by which water is drawn into the cavity, passing between mantle and funnel, and is expelled through the funnel. In swimming the arms are directed forwards, the fins undulate, and the motion is slow and deliberate; but if the animal is threatened or alarmed it swims suddenly and rapidly backwards by expelling water
forcibly from the mantle cavity through the funnel, at the same time expelling a cloud of ink from its ink-sac.

The _Sepia_ feeds principally on Crustacea, and in aquaria has been observed to pursue and capture prawns. The method in which it secures its prey has been carefully observed and described by the present writer, who studied the living animal in the aquarium of the biological laboratory at Plymouth. The prawns support themselves on their long slender legs on convenient points of the rockwork, and the _Sepia_ stalks them with great caution and determination, the rapid play of its chromatophores giving evidence of its excitement. When it has arrived within striking distance, the two tentacular arms are shot out with great rapidity, and the prawn is seized between the two expanded ends, drawn within the circle of short arms, and devoured; unless, as sometimes happens, the prawn springs away and the _Sepia_ misses its aim.

Two species of _Sepia_ occur in British and European waters, including the Mediterranean, namely, _S. elegans_ and _S. officinalis_. The usual length of the body is about 9 or 10 in. They live mostly between ten and forty fathoms, coming into shallower water in July and August to deposit their eggs, which are about as large as black currants and of somewhat similar colour, and are connected by elongated stalks into a cluster attached to the seabottom. Other species occur in various parts of the world, e.g. _S. cultrata_, which is common on the coasts of Australia. The _Sepiidae_ form the only family of cuttle-fishes in which the shell is calcified. They belong to the tribe Myopsida, characterized by the complete closure of the external corneal covering of the eye outside the iris and the lens.

_Sepiola_ and _Rossia_ belong to another family of the Myopsida. Both are British genera living in shallow water, and entering estuaries. The animals of both genera are small, not more than 2 or 3 in. in length, with the body rounded at the aboral end, and the fins short and rounded, inserted in the middle of the body length, instead of extending from end to end. _Sepiola_, although it swims by means of its fins and funnel when active, spends much of its time buried in the sand for concealment. _Rossia_ has similar habits. The shell is chitinous and shorter than the body. In other genera of the _Sepiolidae_ the shell is entirely absent. _Idiosepia_ is the smallest of the Cephalopods, only 1-5 in. in length. It inhabits the Indian Ocean. The body is elongated and the fins rudimentary. In the _Sepiadoridae_ also the shell is absent. The body is short and the mantle united with the head dorsally. The two genera _Sepiadoriurn_ and _Sepiololae_ occur in the Pacific Ocean. The common squid _Loligo_ is the type of the only remaining family of the Myopsida. In this species the shell is a well-developed chitinous pen or gladius with a thickened axis narrowing to a point behind, but bearing posteriorly a wide thin plate on each side. The shape closely resembles that of a quill pen with the quill in front. The fins are large and triangular, extending over rather more than half of the length of the body aborally. The tentacular arms are only partly retractile. The body is elongated and conical, and reaches about a foot in length. The squid is gregarious, and forms a favourite food of the larger fishes, especially of conger. All the Myopsida are more or less littoral in habit, and the British forms are familiar in consequence of their frequent capture in the nets of fishermen. The shell, or "bone" as it is commonly called, of the common _Sepia_ frequently occurs in abundance on the shore among the sea-weed and other refuse left by the tide.

The Oligopsida, or cuttle-fishes in which the corneal covering of the eye is perforated, are on the whole more oceanic than littoral, and many of the species are abyssal. _Ommatostrephe sagitulatus_ is one of the forms that occur off the British coasts, especially the more northern, e.g. in the Firth of Forth. In general appearance it resembles the common squid, but the fins are broader and shorter, not extending to the middle of the body.
The shell is similar to that of Loligo, but ends aborally in a little hollow cone. The suckers bear chitinous rings which are toothed along the outer edge. The tentacular arms are rather short and thick. Two specimens of allied species have been taken on British coasts, one of which, captured off Salcombe in Devonshire in 1892, had a body 66 cm. (22 in.) long, and tentacular arms 64 cm. long, or nearly the same length as the body. Most of the species of Omomastrea are naturally gregarious and oceanic, and occur in the open seas in all latitudes, swimming near the surface and often leaping out of the water. They are largely devoured by albatrosses and other marine birds, and by Cetacea. They are used as bait in the Newfoundland cod fishery.

Some of the oceanic cuttle-fishes reach a very large size, and the stories of these ocean monsters which are narrated by the older writers, though to some extent exaggerated, are now known to be founded on fact. The figure given by one author of a gigantic Cephalopod rising from the surface of the ocean and embracing with its arms a full-rigged ship does not accurately represent an actual occurrence, but on the other hand there are authentic instances on record of fishermen in small boats on the banks of Newfoundland being in great peril in consequence of large squids throwing their arms across their boats. In November 1874 a specimen was brought ashore at St John's, Newfoundland, which had been caught in herring nets. Its body was 7 ft. long, its fins 22 in. broad, and its tentacular arms 24 ft. long. Several others have been recorded, taken in the same region, which were as large or larger, the total length of the body and tentacles together varying from 30 to 52 ft., and the estimated weight of one of them being 1000 lb.

In April 1875 one of these large squids occurred off Bofin Island on the Irish coast. The crew of a currach rowed out to it and attacked it, cutting off two of its arms and its head. The shorter arms measured 8 ft. in length and 15 in. in circumference; the tentacular arms are said to have been 30 ft. long. In the Natural History Museum in London there is one of the shorter arms of a specimen, measuring 5 ft. 6 in. in length and 11 in. in circumference, and the total length of the specimen, including body and tentacles, is stated to have been 40 ft. The maximum known size of these giant squids is stated to be 18 metres or about 58½ ft.

All these gigantic specimens belong, so far as is presented now, to one genus called Architeuthis, referred to the same family as Ommastrephes. They are the largest known invertebrates.

These huge cuttle-fishes as well as those of various other oceanic species form the food of the cachalot or sperm whale, and F. T. Bullen, in his Cruise of the Cachalot and other writings, has graphically described contests which came under his own observation between the cachalot and its prey. The prince of Monaco in his yacht the "Princess Alice" was fortunate enough to be able to make a very complete scientific investigation in the case of one specimen of the cachalot, which not only confirmed the most important of Mr Bullen's statements, but added considerably to our knowledge of oceanic cuttle-fishes. Off the Azores in July 1875 he killed a cachalot 15·70 metres long (about 45 ft. 8 in.) by the crew of a whaler. The animal in its death-agony vomited the contents of its stomach, most of which were carefully collected and preserved, and afterwards examined by Professor Joubin. On the lips of the whale were found impressions several centimetres wide which corresponded exactly to the toothed suckers of the largest cuttle-fish obtained from its stomach. The contents of the stomach consisted entirely of cuttle-fish or parts of cuttle-fish, including the giant Architeuthis, and among them was the body, without the head, of a form new to science, distinguished by a condition of the external surface which occurs in no other species of the group. The surface of the skin was divided into small angular flat projections like scales, arranged in a regular spiral like the scales of a pine cone. From this character the new genus was called Lepidoteuthis. The body, without the head, of the specimen obtained was 86 cm. (nearly 3 ft.) in length.

The family Onychoteuthidae is remarkable for the formidable chitinous hooks borne on the arms. These hooks are special modifications of the toothed chitinous ring which covers the sucker-rim in the Decapoda generally. The teeth of the ring are often unequal in size, and in the Onychoteuthidae one tooth is enormously developed. The maximum development occurs in Verrana, found in the Mediterranean, where the suckers have lost their function and are merely flabby projections bearing the hooks at their extremities. Onychoteuthis reaches a large size, the length of the body without the arms being one specimen from the Pacific coast of America 8 ft. Figures of this and several of the following genera are given in the article CEPHALOPODA.

In the family Cheiroteuthidae many of the species occur at abyssal depths of the ocean, and exhibit curious modifications of structure. In Cheiroteuthis itself the tentacular arms are very long and slender, and are not capable of retraction into pockets. In several species of this genus the suckers are no longer organs of adhesion, but are simple cups containing a network of filaments resembling a fishing net. In Histiotheuthis and Histioptes, as in some Octopods, the six dorsal arms are more or less completely united by a web, which also probably serves for capturing fish. In these two genera and in Callisteuthis the skin bears luminous organs. Cheiroteuthis has been taken at 2600 fms. Callisteuthis at 2200. Histioptes at nearly 2000. Baltyteuthis, placed in the same family as Omomastrea, has been taken at 1700 fms.

The Cranchiidae are remarkable for their small size, the shortness of the ordinary arms, and the protuberance of the eyes, which in Taonius are actually on the ends of stalk-like outgrowths of the body. Cranchius is a deep-sea form taken at 1700 fms. Its body is pear-shaped, swollen posteriorly and quite narrow at the neck.

Spirula is distinguished from all other existing Cephalopods by the structure of its coiled shell, which in many respects resembles those of the extinct Ammonites, and is not completely internal. In the structure of the body the animal is a true cuttlefish in the sense in which the term is here used, having ten arms and a perforated cornea. Three species are distinguished, and their empty shells occur abundantly on the shores of the tropical regions of the Atlantic, Pacific and Indian Oceans. In German the shells are known from their shape as Posthörnchen. They are common on the shores of the Azores. But the animal has very rarely been obtained; only a few specimens occur in museum collections. One specimen was taken by the "Challenger" in a deep-sea trawl, at a depth between 300 and 400 fathoms off Banda Neira in the Moluccas. Dr Willemoes Suhm, in describing the capture, stated that the specimen seemed to have been in the stomach of a fish, as its surface was slightly digested, and he thought it must have habits of concealment which usually prevent its capture, and that it was secured on this occasion only by the capture of the fish which had swallowed it. The fact that the shells are washed ashore in such large numbers is not fully explained. Possibly when freed from the animal the air in the chambers of the shell causes it to float, and in that case it would naturally be sooner or later washed ashore.

(From "The Cephalopods: Their Life-History, Structure and Classification," by J. S. Agassiz.)
at the battle of the Boyne, and at the siege of Limerick (where he was wounded), and King William created him Baron Cutts of Gowran in the kingdom of Ireland. In 1691 he succeeded to the command of the brigade of the prince of Hesse (wounded at Aughrim), and on the surrender of Limerick was appointed commandant of the town. Next year he served again in Flanders, as a brigadier, his brigade of Mackay's division being one of those almost destroyed at Steinkirk. At this battle Cutts himself was wounded. For some time after this, Lord Cutts was lieutenant-governor of the Isle of Wight, but he returned to active service in 1694, holding a command in the disastrous Brest expedition. He was one of Carmarthens's companions in the daring reconnaissance of Camaret Bay, and was soon afterwards again wounded. He succeeded Talmarsh, the commander of the expedition (who died of his wounds), as colonel of the Coldstream Guards. Next year, after serving as a commissioner for settling the bank of Antwerp, he distinguished himself once more at the famous siege of Namur, winning for himself the name of "Salamander" by his indifference to the heaviest fire. Henceforward court service and war service alternated. He was deep in the confidence of William III., and acted as a diplomatic agent in the negotiations which ended in the peace of Ryswick. On the occasion of the great fire in Whitehall (1698) Cutts, at the head of the Coldstreamers, earned anew the honourable nickname of "the Salamander," which General Walmesley bestowed upon him as his private secretary. In 1702, now a major-general, Cutts was serving under Marlborough in the opening campaigns of the War of the Spanish Succession, and at the siege of Venloo, conspicuous as usual for romantic bravery, he led the stormers at Fort Saint Michael. His enemies, and even the survivors of the assault, were amazed at the success of a seemingly hare-brained enterprise. Probably, however, Cutts, who was now a veteran of great and varied experience, measured the factors of success and failure better than his critics. It was on this occasion that Swift lampooned the lieutenant-general in his Ode to a Salamander. He made the campaign of 1703 in Flanders, and in 1704, after a visit to England, he rejoined Marlborough on the banks of the Danube. At Blenheim he was third in command, and it was his division that bore the brunt of the desperate fighting at the village which gave its name to the battle.

Blenheim was Cutts's last battle. His remaining years were spent at home, and, at the time of his death, he was the holder of eight distinct political and military offices. He sat in five parliaments for the county of Cambridge, and in Queen Anne's first Parliament he was returned for Newport in the Isle of Wight, for which he had been the most successful in the time of his death. He was twice married, but left no issue.

CUVIER, GEORGES LÉOPOLD CHRISTEN FRÉDÉRIC DAGOBERT, BARON (1769-1832), French naturalist, was born on the 23rd of August 1769 at Montbéliard, and was the son of a retired officer on half-pay belonging to a Protestant family which had emigrated from the Jura in consequence of religious persecution. He early showed a bent towards the investigation of natural phenomena, and was noted for his studious habits and marvellous memory. After spending four years at the Academy of Stuttgart, he accepted the position of tutor in the family of the Comte d'Héricy, who was in the habit of spending the summer near Fécamp. It thus came about that he made the acquaintance of the agriculturist, A. H. Tessier, who was then living at Fécamp, and who wrote strongly in favour of his protégé to his friends in Paris— with the result that Cuvier, after corresponding with the well-known naturalist E. Geoffroy Saint-Hilaire, was appointed in 1793 assistant to the professor of comparative anatomy at the Musée d'Histoire Naturelle. The National Institute was founded in the same year and he was elected a member. In 1796 he began to lecture at the École Centrale du Panthéon, and at the opening of the National Institute in April, he read his first palaeontological paper, which was subsequently published in 1800 under the title Mémoires sur les espèces d'êléphants vivants et fossiles. In 1798 was published his first separate work, the Tableau élémentaire de l'histoire naturelle des animaux, which was an abridgment of his course of lectures at the École du Panthéon, and may be regarded as the foundation and first and general statement of his natural classification of the animal kingdom.

In 1799 he succeeded L. J. Maubenton as professor of natural history in the Collège de France, and in the following year he published the Leçons d'anatomie comparée, a classical work, in the production of which he was assisted by A. M. C. Duméril in the first two volumes, and by G. L. Duvornoy in three later ones. In 1802 Cuvier became titular professor at the Jardin des Plantes; and in the same year he was appointed commissary of the Institute to accompany the inspectors-general of public instruction. In this latter capacity he visited the south of France; but he was in the early part of 1803 chosen perpetual secretary of the National Institute in the department of the physical and natural sciences, and he consequently abandoned the appointment just mentioned and returned to Paris.

He now devoted himself more especially to three lines of inquiry—one dealing with the structure and classification of the mollusca, the second with the comparative anatomy and systematic arrangement of the fishes, and the third with fossil mammals and reptiles primarily, and secondarily with the osteology of living forms belonging to the same groups. His papers on the mollusca began as early as 1792, but most of his memoirs on this branch were published in the Annales du museum between 1802 and 1815; they were subsequently collected as Mémoires pour servir à l'histoire et à l'anatomie des mollusques, published in one volume at Paris in 1817. In the department of fishes, Cuvier's researches, begun in 1801, finally culminated in the publication of the Histoire naturelle des poissons, which contained descriptions of 5000 species of fishes, and was the joint production of Cuvier and A. Valenciennes, its publication (so far as the former was concerned) extending over the years 1828-1831. The department of palaeontology dealing with the Mammalia may be said to have been essentially created and established by Cuvier. In this region of investigation he published a long list of memoirs, partly relating to the boxes of extinct animals, and partly detailing the results of observations on the skeletons of living animals specially examined with a view of throwing light upon the structure and affinities of the fossil forms. In the second category must be placed a number of papers relating to the osteology of the Rhinoceros Indicus, the tapir, Hyæna Cana, the hippopotamus, the sloths, the manatee, &c., while in the former category must be classed an even greater number of memoirs, dealing with the extinct mammals of the Eocene beds of Montmartre, the fossil species of hippopotamus, the Didelphys gyposorum, the Megalonyx, the Megatherium, the cave-hyæna, the extinct species of rhinoceros, the cave-bear, the mastodon, the extinct species of elephant, fossil species of manatee and seals, fossil forms of crocodilians, chelonians, fishes, birds, &c. The results of Cuvier's principal palaeontological and geological investigations were ultimately given to the world in the form of two separate works. One of these is the celebrated Recherches sur les ossemens fossiles de quadrupèdes, published in Paris in 1812, with subsequent editions in 1821 and 1825; and the other is his Discours sur les révolutions de la surface du globe, published in Paris in 1825.

But none of his works attained a higher reputation than his Règne animal distribué d'après son organisation, the first edition of which appeared in four octavo volumes in 1817, and the second in five volumes in 1829-1830. In this classical work Cuvier embodied the results of the whole of his previous researches on the structure of living and fossil animals. The whole of the work was his own, and he was assisted by his friend P. A. Latreille.

Apart from his own original investigations in zoology and palaeontology Cuvier carried out a vast amount of work as perpetual secretary of the National Institute, and as an official connected with public education generally; and much of this work appeared ultimately in a published form. Thus, in 1808 he was placed by Napoleon upon the council of the Imperial University, and in this capacity he presided (in the years 1809,
1811 and 1813) over commissions charged to examine the state of the higher educational establishments in the districts beyond the Alps and the Rhine which had been annexed to France, and to report upon the means by which these could be connected with the central university. Three separate reports on this subject were published by him. In his capacity, again, of perpetual secretary of the Institute, he not only prepared a number of "éloges historiques" on deceased members of the Academy of Sciences, but he was the author of a number of reports on the history of the physical and natural sciences, the most important of these being the *Rapport historique sur le progrès des sciences physiques depuis 1789*, published in 1810. Prior to the fall of Napoleon (1814) he had been admitted to the council of state, and his position remained unaffected by the restoration of the Bourbons. He was elected chancellor of the university, in which capacity he acted as interim president of the council of public instruction, whilst he also, as a Lutheran, superintended the faculty of Protestant theology. In 1819 he was appointed president of the committee of the interior, and retained the office until his death. In 1826 he was made grand officer of the Legion of Honour; and in 1831 he was raised by Louis Philippe to the rank of peer of France, and was subsequently appointed president of the council of state. In the beginning of 1832 he was nominated to the ministry of the interior, but on the 13th of May he left for Rome, and in Paris after a brief illness.

**CUVILLES, FRANÇOIS DE** (1668–c. 1707), French architect and engraver. He helped to carry the French rococo taste to Germany—he was summoned about 1720 to Cologne by the elector James Clement; in 1738 he became architect to the elector of Bavaria, and afterwards occupied the same position towards the emperor Charles VII. His style, while essentially thin, is often painfully elaborate and bizarre. He designed mirrors and consoles, balustrades for staircases, ceilings and fireplaces, and in furniture, beds and commodes especially. He also laid out parks and gardens. He wrote several treatises on artistic and decorative subjects, which were edited by his son, François de Cuvilles the younger, who succeeded his father at the court of Munich.

**CUXHAVEN, or CUXHAVEN**, a seaport town of Germany, belonging to the state of Hamburg, and situated at the extremity of the west side of the mouth of the Elbe, 71 m. by rail N.W. from Hamburg. Pop. (1900) 6898. The harbour is good and secure, and is much frequented by vessels delayed in the Elbe by unfavourable weather. A new harbour was made in 1801–1806, having a depth of 20 ft., with a fore port 1000 ft. long by 800 ft. wide; and it is now the place of departure and arrival of the mail steamers of the Hamburg-American Steamship Company, who in 1901 transferred here a part of their permanent staff. The port is free, i.e. outside the customs union (*Zollverein*), the imports being principally coals, bricks and timber, and the exports fish. There is a fishing fleet, for which a new harbour was opened in 1802. Though lying on a bare strand, the town is much frequented as a bathing place by Hamburgers. It is strongly fortified, and there is a lighthouse, and lifeboat and pilot stations. The town only dates from 1875, having been formed by uniting the villages of Ritzebiel and Cuxhavens, which had belonged to Hamburg since 1304.

**CUYABÁ, or CUYABÁ**, capital of the inland state of Matto Grosso, Brazil, about 972 m. N.W. of Rio de Janeiro, on the Cuyabá river near its discharge into the São Lourenço, the principal Brazilian tributary of the Paraguay. Pop. (1809) 25,407. The surrounding country is thickly populated. Cuyabá has uninterrupted steamer communication with Montevideo, about 2500 m. distant, but has no land communication with the national capital, except by telegraph. The climate is hot and malaria is prevalent. Cuyabá was founded in 1719 by Paulista gold hunters, and its gold-washings, now apparently exhausted, yielded rich results in the 18th century. It is the seat of a bishopric and headquarters of an important military district, having an arsenal and military barracks.

**CUYAPO, a town of the province of Nueva Ecija, Luzon, Philippine Islands, 28 m. N.N.W. of San Isidro, the capital. Pop. (1903) 16,292. Rice is grown here. In 1907 the town of Nampicuan was formed from part of Cuyapo.**

**CUYP, the name of a Dutch family which produced two generations of painters. The Cuyps were long settled in Dordrecht, in the neighbourhood of which they had a country house, where Albert CuyP (the most famous) was born and bred. The eldest member of the family acquired fame was JACOB GERRITsz CUYP, born it is said at Dordrecht in 1675, and taught by Abraham Bloemaert of Utrecht. He is known to have been alive in 1649, and the date of his death is obscure. J. G. Cuyp's pictures are little known. But he produced portraits in various forms, as busts and half-lengths thrown upon plain backgrounds, or groups in rooms, landscapes and gardens. Solid and clever as an imitator of nature in his ordinary garb, he is always spirited, sometimes rough, but generally plain, and quite as able to sit of the tinkle of sculpture as in Frans Hals as in the concentrated light-effects peculiar to Rembrandt. In portrait busts, of which there are signed examples dated 1624, 1644, 1646 and 1649, in the museums of Berlin, Rotterdam, Marseilles, Vienna and Metz, his treatment is honest, homely and true; his touch and tone firm and natural. In portraying children he is fond of introducing playthings and pets—a lamb, a goat or a roedeer; and he reproduces animal life with realistic care. In a family scene at the Amsterdam Museum we have likenesses of men, women, boys and girls with a cottage and park. In the background is a coach with a pair of horses. These examples alone give us a clue to the influences under which Albert Cuyp grew up, and explain to some extent the direction which his art took as he rose to manhood.

**ALBERT CUYP (1620–1691), the son of Jacob Gerritz CuyP by Grieteh Dierichsdochter (Dierich's daughter), was born at Dordrecht. He married in 1658 Cornelia Bosman, a rich widow, by whom he had an only daughter. By right of his possessions at Dordwijk, Cuyp was a vassal of the county of Holland, and possessed various rights. He was twice mayor of the town, and he was bequeathed a house and garden by his father. He was sufficiently well known to be placed on the list of those from whom William III., stadtholder of the Netherlands, chose the regency of Dordrecht in 1672. His death, and his burial on the 7th of November 1691 in the church of the Augustines of Dordrecht, are historically proved. But otherwise the known facts concerning his life are few. He seldom dates his pictures, but it appears probable that he ceased to paint about 1675. It has been said that Albert was the pupil of his father. The scanty evidence of Dutch annalists to this effect seems confirmed by a certain coincidence in the style and treatment of father and son. That he was a pupil of van Goyen has been surmised on the strength of the style of his early works. It has been likewise stated that Albert was skilled, not only in the production of portraits, landscapes and herds, but in the representation of still life. His works are supposed to be divisible into such bear the distinctive marks C. or A. C. in cursive characters, the letters A. C. in Roman capitals, and the name "A. CuyP" in full. A man of Cuyp's acknowledged talent may have been versatile enough to paint in many different styles. But whether he ever performed as some critics have thought is a question not easily to answer. It is to be observed that pieces assigned to CuyP representing game, shell-fish and fruit, and inscribed A. C. in Roman capitals (Rotterdam, Amsterdam and Berlin museums), though cleverly executed, are not in touch or treatment like other pictures of less dubious authenticity, signed either with C. or A. C. or "A. CuyP" in cursive letters. The panels marked C. and A. C. in cursive are portraits or landscapes, with herds, and interiors of stables or sheds, in which there are cows, horses and poultry. The subjects and their handling are akin to those which strike us in panels bearing the master's full
signature, though characterized, as productions of an artist in the first phase of his progress would naturally be, by tones more uniform, touch more flat, and colour more deep than we find in the delicate and subtle compositions of the painter’s later time. Generally speaking, the finished examples of Cuyp’s middle and final period all bear his full signature. They are all remarkable for harmonies attained by certain combinations of shades in gradations with colours in contraposition.

Albert Cuyp, a true child of the Netherlands, does not seem to have wandered much beyond Rotterdam on the one hand or Nijmegen on the other. His scenery is that of the Meuse or Rhine exclusively; and there is little variety to notice in his views of water and meadows at Dordrecht, or the bolder undulations of the Rhine banks east of it, except such as results from diversity of effect due to change of weather or season or hour. Cuyp is to the river and its banks what Willem Van de Velde is to calm seas and Hobbema to woods. There is a poetry of effect, an eternity of distance in his pictures, which no Dutchman ever expressed in a similar way. His landscapes sparkle with silvery sheen at early morning, they are bathed in warm or sultry haze at noon, or glow with heat at eventide. Under all circumstances they have a peculiar tinge of aurich which is Cuyp’s and Cuyp’s alone. Bürger truly says van Goyen is gray, Ruysdael is brown, Hobbema olive, but Cuyp “is blond.” The utmost delicacy may be observed in Cuyp’s manner of defining reflections of objects in water, or of sight from water on ship’s sides. He shows great cleverness in throwing pale-yellow clouds against clear blue skies, and merging yellow mists into olive-green vegetation. He is also very artful in varying light and shade according to distance, either by interchange of cloud-shadow and sun-gleam or by gradation of tints. His horses and cattle are admirably drawn, and they relieve each other quite as well if contrasted in black and white and black and red, or varied in subtle shades of red and brown. Rural growth is expressed by light but marrowly touch, suggestive of detail as well as of general form. The human figure is given with homely realism in most cases, but frequently with a charming elevation, when, as often occurs, the persons represented are meant to be portraits. Whatever the theme may be it remains impressed with the character and individuality of Cuyp. Famous subjects of the master’s earlier period are stables with cattle and horses (Rotterdam, Amsterdam, Petersburg and museum). Occasionally he painted portraits in the bust form familiar to his father, one of which is dated 1649, and exhibited in the National Gallery, London. More frequently he produced likenesses of ladies and gentlemen on horseback, in which the life and dress of the period and the forms of horses are most vividly represented (Buckingham Palace, Bridgewater Gallery, Louvre and Dresden Museum). Later on we find him fondest of expansive scenery with meadows and cattle and flocks, or rivers and barges in the foreground and distances showing the towers and steeples of Dordrecht. Cuyp was more partial to summer than to winter, to noon than to night, to calm than to storm. But some of his best groups are occasionally relieved on dark and gusty cloud (Louvre and Robert’s collection). A few capital pieces show us people sledding and skating and netting ice-holes (Yarborough, Need and Bedford collections). A lovely “Night on the Banks of a River,” in the Grosvon collection, reminds us that Cuyp’s friend and contemporary was the painter of moonlight, Aert van der Neer, and that he was equal in the production of these peculiar effects and superior in the throw of figures. Sometimes Cuyp composed fancy subjects. His “Ones charm the Beasts,” in the Bute collection, is judiciously arranged with the familiar domestic animals in the foreground, and the wild ones, to which he is a comparative stranger, thrown back into the distance. One of his rare gospel subjects is “Philip baptizing the Eunuch” (Marchmont House, Berwickshire), described as a fine work by Waagen. The best and most attractive of Cuyp’s pieces are his Meuse and Rhine landscapes, with meadows, cattle, flocks and horsemen, and occasionally with boats and barges. In these he brought together and displayed—during his middle and final period—all the skill of one who is at once a poet and a finished artist; grouping, tinting, touch, harmony of light and shade, and true chords of colours are all combined. Masterpieces of acknowledged beauty are the “Riders with the Boy and Herdsmen” in the National Gallery; the Meuse, with Dordrecht in the distance, in three or four collections; the Bridgewater, Grosvon, Hoflord and Brownlow collections; the “Huntsman” (Ashburton); “Herdsmen with Cattle,” belonging to the marquess of Bute; and the “Piper with Civ.,” in the Louvre. The prices paid for Cuyp’s pictures in his own time were comparatively low. In 1750, 30 florins was considered to be the highest sum to which any one of his panels was entitled. But in more recent times the value of the pictures has naturally risen very largely. At the sale of the Clewer collection at Christie’s in 1876 a small “Hilly Landscape in Morning Light” was sold for £540, and a view on the Rhine, with cows on a bank, for £3150.

John Smith’s Catalogue raisonné of the Dutch and Flemish painters, in 9 vols. (1840), enumerated 335 of Albert Cuyp’s works, of which in 1877 Sir J. A. Crowe wrote in this encyclopaedia that “it would be almost impossible to find more than a third of them.” In C. Hofstede de Groot’s Catalogue raisonné, vol. ii. (1909), revising Smith’s, the number is extended to nearly 850, but he accepts too readily the attributions of false catalogues; the work is, however, the best modern authority on the painter.

CUZA (or COUZA), ALEXANDER JOHN [Alexandru Ioan] (1820–1873), first prince of Rumania, was born on the 20th of March 1820, at Galatz in Moldavia, and belonged to an ancient boiar, or noble, family. He was educated at Jassy, Pavia, Bologna and Athens; and, after a brief period of military service, visited Paris from 1837 to 1840 for a further course of study. In 1845 he married the daughter of another boiar, Elena Rosetti, who in 1862 founded the Princess Elena refuge for orphans, at Bucharest. Cuza was imprisoned by the Russian authorities for taking part in the Rumanian revolution of 1848, but escaped to Vienna. On his return, in 1850, he was appointed prefect of Galatz. In 1857 he rejoined the army, and within a few months rose to the rank of colonel. He became minister of war in 1858, and represented Galatz in the Assembly which was elected in the same year to nominate a prince for Moldavia. Cuza was a prominent speaker in the critical debates which ensued when the assembly met at Jassy, and strongly advocated the union of the two Danubian principalities, Moldavia and Walachia. In default of a foreign prince, he was himself elected prince of Moldavia by the assembly at Jassy (17th Jan. 1859), and prince of Walachia by the assembly at Bucharest (5th Feb.). He thus became ruler of the united principalities, with the title Prince Alexander John I.; but as this union was forbidden by the congress of Paris (18th Oct. 1858), his authority was not recognized by his suzerain, the sultan of Turkey, until the 23rd of December 1861, when the union of the principalities under the name of Rumania was formally proclaimed. For a full account of Cuza’s reign see RUMANIA. The personal vices of the prince, and the drastic and unconstitutional reforms which he imposed on all classes, alienated his subjects, although many of these reforms proved to be of lasting excellence. Financial distress supervened, and the popular discontent culminated in revolution. At four o’clock on the morning of the 22nd of February 1866, a band of military conspirators broke into the palace, and compelled the prince to sign his abdication. On the following day they conducted him safely across the frontier. Prince Alexander spent the remainder of his life chiefly in Paris, Vienna and Wiesbaden. He died at Heidelberg on the 15th of May 1873.

CUZCO, an inland city of southern Peru, capital of an Andean department of the same name, about 360 m. E.S.E. of Lima, in lat. 13° 31' S., long. 73° 03' W. The population, largely composed of Indians and mestizos, was estimated at 30,000 in 1866, but according to the official estimate of 1906, it was then about 25,000 less. The city stands at the head of a small valley, 11,380 ft. above sea-level, and is nearly enclosed by mountains of considerable elevation. The valley itself is 9 m. in length and extends S.E. to the valley of Vilcamayu. Overlooking the city from the N. is the famous hill of Sacasahuaman, crowned by ruins of the cyclopean fortress of the Incas and their predecessors, and separated from adjacent heights by the deep ravines of two
streams, called the Huatenay and Rodadero. The principal part of the city lies between these two streams, with its great plaza in the centre. On the W. side of the Huatenay are two more fine squares, called the Cabildo and San Francisco. The houses of the city are built of stone, their walls commonly showing the massive masonry of the Incas at the bottom, crowned with a light modern superstructure roofed with red tiles. The streets cross each other at right angles and afford fine vistas on every side. The principal public buildings are the cathedral, which is classed among the best in South America, the convent of San Domingo, which partly occupies the site of the great Temple of the Sun of the Incas, the cabildo or government-house, a university founded in 1568, a college of science and arts, a public library, hospital, mint and museum of Incarail antiques. Cuzco was made the seat of a bishopric soon after it was occupied by the Spaniards. The Church has always exercised a dominating influence in this region, and the city has many churches and religious establishments. There are a number of small manufacturing industries in Cuzco, including the manufacture of cotton and woollen fabrics, leather, beer, embroidery and articles of gold and silver. Its trade is not large, however, owing to the costs of transportation. The climate is cool and bracing, and the products of the vicinity include many of the temperate zones. A railway from Junin to Juncas (a station near Mollendo) to Puno is under construction and was virtually completed early in 1908. This railway gives Cuzco an outlet to the coast, and also direct connexion with La Paz, the Bolivian capital. A branch of the Callao & Oroya railway is also projected southward to Cuzco, and reached Huancayo in 1908. Cuzco was the capital of a remarkable empire ruled by the Incas previous to the discovery of Peru, and it was one of the largest and most civilized of the native cities of the New World. It was captured by Pizarro in 1533, and it is said that its size and the magnificence of its principal edifices filled the Spaniards with surprise. It was for many years an object of contention among the Spanish factions, but ultimately the greater attractions of Lima and its own isolation diminished its importance.

The department of Cuzco is the second largest in Peru, having an area of 156,317 sq. m., and a population, according to a reduced official estimate of 1906, of only 328,980. It occupies an extremely mountainous region on the frontier of Bolivia, E. of the departments of Junin, Ayacucho and Apurimac, and extends from Loreto on the N. to Puno and Arequipa on the S. Its area, however, includes a large part of what is claimed by Bolivia, and the settlement of the dispute may materially diminish its size. The elevation of a large part of the department is a temperate climate and permits the cultivation of cereals and other products of the temperate zone. Cattle and sheep are produced in large numbers in some of the provinces, while in others mining forms the chief industry. On the eastern forested slopes and in the lower valleys tropical conditions prevail. The population is chiefly composed of Indians who form a sturdy, docile labouring class, but are in great part strongly disinclined to accept the civilization of the dominant white race.

**CYANAMIDE—CYANIC ACID**

Cyanamide, NC-NH₃, the amide of normal cyanic acid, obtained by the action of ammonia on cyanogen chloride, bromide or iodide, or by the desulphurization of thiourea with mercuric oxide; it is generally prepared by the latter process. It forms white crystals, which melt at 40°C, and are readily soluble in water, alcohol and ether. Heated above its melting point it polymerizes to di-cyanamide (CN₂H₄), which at 130°C is transformed into the polymer n-tri-cyanamido or melamine (CN₃H₆), the mass solidifying. Nascent hydrogen reduces cyanamide to amino cyanic acid. It gives mono-metallic salts of the type NC-NHM when treated with aqueous or alcoholic solutions of alkalis. Di-metallic salts are obtained by heating cyanates alone, e.g. calcium, or cyanides in a current of nitrogen, e.g. barium.

Calcium cyanamide has assumed importance in agriculture since the discovery of its economic production in the electric furnace, wherein calcium carbide takes up nitrogen from the atmosphere to form the cyanamide with the simultaneous liberation of carbon. It may also be produced by heating lime or chalk with charcoal to 2000°C in a current of air. The commercial product (which is known in Germany as "Kalkhitte"") contains from 14 to 22% of nitrogen, which is liberated as ammonia when the substance is treated with water; to this decomposition it owes its agricultural value. It appears that with soils which are not rich in humus or not deficient in lime, calcium cyanamide is almost as good, nitrogen for nitrogen, as ammonium sulphate or sodium nitrate; but it is of doubtful value with peaty soils or soils containing little lime, nor is it usefully available as a top-dressing or for storing.

**CYANIC ACID AND CYANATES.** Cyanic acid, CN-OH, was discovered by F. Wöhler in 1824, and may be obtained by distilling its polymeride, cyanic acid, in a current of carbon dioxide (F. Wöhler and J. v. Liebig, Berzelius Jahresberichte, 1827, 11, p. 84), the vapours which distil over being condensed in a freezing mixture. It is a very volatile liquid of strong acid reaction, and is only stable below 0°C. It has a smell resembling that of acetic acid. At 0°C it is rapidly converted into a mixture of cyanic acid, C₃N₂O₂H₅, and another polymer, cyanemide (CNH₇O); this latter substance is a white amorphous powder, insoluble in water. An aqueous solution of cyanic acid is rapidly hydrolysed above 6°C into a mixture of carbon cyanate and cyanamide (C₃N₂O₂CN), which, may be regarded as the chloride of cyanic acid. It may be prepared by the action of chloride on hydrocyanic acid or on mercury cyanide. It is a very poisonous volatile liquid, which boils at 15°-20°C. It polymerizes readily to cyanuric chloride, C₄N₅Cl₂.

Caucasian alkalis hydrolyse it readily to the alkali chloride and cyanate.

The salts of cyanic acid are known as the two most important being potassium cyanate (KOCN) and ammonium cyanate (NH₄OCN). Potassium cyanate may be prepared by heating potassium cyanide with an oxidizing agent, or by heating potassium ferrocyanide with manganese dioxide, potassium carbonate or potassium dichromate (J. v. Liebig, Ann., 1841, 38, p. 108; C. Lea, Jahresb., 1861, p. 789; L. Gattermann, Ber., 1890, 23, p. 1224), the fused mass being extracted with boiling alcohol. It crystallizes in flat plates and is readily soluble in cold water. It is a somewhat important reagent, and has been used by Emil Fischer in various syntheses of the uric acid group (see PYRIN). Ammonium cyanate possesses considerable theoretical importance since the first synthetic preparation of an organic from inorganic compounds was accomplished by warming a solution of cyanic acid with ammonia (Ber., 1828, 12, p. 266). J. Walker and J. K. Wood (Jour. Chem. Soc., 1900, 77, p. 24) prepared pure ammonium cyanate by the union of gaseous ammonia and cyanic acid, special precautions being taken to keep the temperature below the point at which the salt is transformed into urea. It crystallizes in fine needles, which melt suddenly at about 80°C, then resolidify, and melt again at about 128° to 130°C (this temperature being that of the melting point of urea). Substituted ammoniums were also made to combine with cyanic acid, and it was found that the substituted ammonium cyanates produced pass much more readily into the corresponding ura than ammonium cyanate itself. (On the constitution of cyanic acid see F. D. Chattaway and J. M. Wadmore, Jour. Chem. Soc., 1902, 241, p. 197.)

Esters of normal cyanic acid are not known, but those of isocyanic acid (HN-Co) may be prepared by the action of alkyl halides on silver cyanate, or by oxidizing the isonitriles with mercuric oxide. They are volatile liquids which boil with decomposition, and possess a nauseating smell. When hydrolysed with caustic alkalis they yield primary amines (this reaction determines their constitution). C₂H₃NCO + H₂O = C₂H₃NH₂ + CO₂. When heated with water they yield carbon dioxide and symmetrical dialkyl urea; with ammonia and amines they form alkyl ureas; and with acid anhydrides they yield tertiary amides.

Ethyl isocyanate, C₂H₅NCO, was first prepared by A. Wurtz (Ann. chim., 1854, 3, 42, p. 43) by distilling a mixture of potassium...
ethyl sulphate and potassium cyanate. It is a colourless liquid which boils at 60°C.

Cyanuric acid, H₃C₆N₃O₆, was obtained by Wöhler and Liebig by heating urea, and by A. Wurtz by passing chlorine into melting urea. It forms white efflorescent crystals. Treatment with phosphorus pentachloride gives cyanuric chloride, C₆N₃Cl₃, which is also formed by the combination of anhydrous chlorine and prussic acid in the presence of sunlight. These substances contain a ring of three carbon and three nitrogen atoms, i.e. they are symmetrical triazines.

**Cyanide**, in chemistry, a salt of prussic or hydrocyanic acid, the name being usually restricted to inorganic salts, i.e. the salts of the metals, the organic salts (or esters) being termed nitriles. The preparation, properties, etc., of cyanides are treated in the article Paussian Acid; reference should also be made to the articles on the particular metals. The most important cyanide commercially is potassium cyanide, which receives application in the "cyanide process" of gold extraction (see Gold).

**Cyanite**, a native aluminium silicate, Al₄Si₅O₁₄, crystallizing in the anorthic system. It has the same percentage chemical composition as andalusite and sillimanite, but differs from these in its crystallographic and physical characters. P. Groth writes the formula as a metasilicate (Al₂O₅SiO₄). The name cyanite was given by A. G. Werner in 1789, from κίανος, blue, in allusion to the characteristic colour of the mineral; the form kyanite is also in common use, and the name disthène, proposed by R. J. Hajiy in 1801, is used by French writers.

Distinctly developed crystals with terminal planes are rare, the mineral being commonly found as lamellar cleavage masses or long blade-shaped crystals embedded in crystalline rocks. The colour is usually a pale sky-blue, but may be white, greenish or yellowish; it varies in intensity in different widths, so that the crystals usually present a more or less striped appearance. There is a perfect cleavage parallel to the broad face m (100), and a less perfect one parallel to l (010); the basal plane p (001), oblique to the prism zone, is a gliding plane on which secondary twinning is produced by pressure, giving rise to characteristic horizontal striations on the cleavage face m. The accompanying figure represents a crystal twinned on the plane m (100). A negative biaxial optical figure is seen in convergent polarized light through the cleavage plane m, the axial plane being inclined at about 30° to the edge between m and t. A remarkable feature of cyanite is the great difference in hardness on different faces of the same crystal and in different directions on the same face: on the face m in a direction parallel to the edge between m and p the hardness is 7, whilst in a direction parallel to the edge between m and l it is 4½. The name disthène, from δις, two, and θέντη, strong, has reference to these differences in hardness.

An analysis of cyanite often shows the presence of a small amount (usually less than 1%) of ferric oxide and sometimes traces of copper, and to these constituents the blue or green colour of the mineral is doubtless due. The mineral is infusible before the blowpipe, and is not decomposed by acids. At a high temperature, about 1350°C, it becomes transformed into sillimanite, changing in specific gravity from 3·6 to 3·2.

Cyanite is a characteristic mineral of the metamorphic crystalline rocks—gneiss, gneis, schist, granulite and eclogite—and is often associated with garnet and staurolite. A typical occurrence is in the white, fine-scaled paragonite-schist of Monte Campione, near St Gotthard in Switzerland, where long transparent crystals of a fine blue colour are abundant. In the gneiss of the Pintscher Tal near Sterzing in Tirol a white variety known as thaitzite is found. It occurs at several places in Scotland, for instance, at Botriphine in Banffshire, with muscovite in a quartz-vein. Fine specimens are found in mica-schist at Chestfield in Massachusetts, and at several other localities in the United States. It is found in the gold-washings of the southern Urals and in the diamond-washings of Brazil. As minute crystal fragments it is met with in many sands and sandstones.

When of sufficient transparency and depth of colour (deep cornflower-blue) the mineral has a limited application as a gem-stone; it is usually cut en cabochon.

(C. L. S.)

**Cyanogen** (Gr. κιάνος, blue γεννάω, to produce), C₆N₃, in chemistry, a gas composed of carbon and nitrogen. The name was suggested by Prussian blue, the earliest known compound of cyanogen. It was first isolated in 1815 by J. Gay-Lussac, who obtained it by heating mercury or silver cyanide; this discovery is of considerable historical importance, since it recorded the isolation of a "compound radical." It may also be prepared by heating ammonium oxalate; by passing induction sparks between carbon points in an atmosphere of nitrogen (see H. von Wartenburg, Abst. J.C.S., 1807, i. p. 299), or by the addition of a concentrated solution of potassium cyanide to one of copper sulphate, the mixed solutions being then heated. It also occurs in blast-furnace gases. When cyanogen is prepared by heating mercuric cyanide, a residue known as para-cyanogen, (CN₄), is left; this is to be regarded as a polymer of cyanogen. It is a brownish amorphous solid, which is insoluble in water. Cyanogen is a colourless gas, possessing a peculiar characteristic smell, and is very poisonous. It burns with a purple flame, forming carbon dioxide and nitrogen; and may be condensed (by cooling to −25°C.) to a colourless liquid, and further to a solid, which melts at 34–4°C. (M. Faraday, Ann., 1845, 58, p. 158). It dissolves readily in water and the aqueous solution decomposes on standing; a dark-brown flocculent precipitate of azulic acid, C₆H₄N₂O, separating whilst ammonium oxalate, urea and hydrocyanic acid are found in the solution. In many respects it resembles chlorine in its chemical behaviour, a circumstance noted by Gay-Lussac; it combines directly with hydrogen (at 500° to 550°C.) to form hydrocyanic acid, and with chlorine, bromine, iodine and sulphur, to form cyanogen chloride, etc.; it also combines directly with zinc, cadmium and iron to form cyanides of these metals. It combines with sulphuretted hydrogen, in the presence of water, to form the compound C₆N₃H₂S, and in the presence of alcohol, to form the compound C₆N₃H₂S. Concentrated hydrochloric acid converts it into oxamide. Potash solution converts it into a mixture of potassium cyanate and cyanide. When heated with hydriodic acid (specific gravity 1·06) it forms amino-acetic acid, and with tin and hydrochloric acid it yields ethylene diamine.

**Cyaxares** (Pers. عاخشتر), king of Media, reigned according to Herodotus (i. 107) forty years, about 624–584 B.C. That he was the real founder of the Median empire is proved by the fact that in Darius's time a Median usurper, Fravartish, pretended to be his offspring (Behistun inscr. 2. 43); but about his history we know very little. Herodotus narrates (i. 103 ff.) that he renewed the war against the Assyrians, in which his father Phraortes had perished, but was, while he besieged Nineveh, attacked by a great Scythian army under Madyas, son of Protobas, which had come from the northern shores of the Black Sea in pursuit of the Cimmerians. After their victory over Cyaxares, the Scythians conquered and wasted the whole of western Asia, and ruled twenty-eight years, till at last they were made drunk and slain by Cyaxares at a banquet (cf. another story about Cyaxares and a Scythian host in Herod. i. 73). As we possess scarcely any contemporary documents it is impossible to find out the real facts. But we know from the prophecies of Jeremiah and Zephaniah that Syria and Palestine were really invaded by northern barbarians in 626 B.C., and it is probable that this invasion was the principal cause of the downfall of the Assyrian empire (see MEDIA and PERSIA: Ancient History).

After the destruction of the Scythians Cyaxares regained the supremacy, renewed his attack on Assyria, and in 606 B.C. destroyed Nineveh and the other capitals of the empire (Herod. i. 106; Berossus ap. Euseb. Chron. i. 29, 37, confirmed by a stele of Nabonidus found in Babylonia; Schei in Recueil de
CYBELE—CYCLAMEN

troussau, xviii.; Messerschmidt, "Die Inschrift der Stele Naboanids," in Mitteilungen der vorderasiatischen Gesellschaft, i, 1896). According to Berossus the wife of Nabonids, whose son Nebuchadrezzar married Amyitis, daughter of the Median king (who is wrongly called Astyages).

The countries north and east of the Tigris and the northern part of Mesopotamia with the city of Harran (Carrhae) became subject to the Medes. Armenia and Cappadocia were likewise subdued; the attempt to advance farther into Asia Minor led to a war with Alyattes of Lydia. The decisive battle, in the sixth year, was interrupted by the famous solar eclipse on the 28th of May 585 predicted by Thales. Syennesis of Cilicia and Nebuchadrezzar (in Herodotus named Labytus) of Babylon interceded and effected a peace, by which the Halys was fixed as frontier between the two empires, and Alyattes's daughter married to Cyaxares's son Astyages (Herod. i. 74).

If Herodotus's dates are correct, Cyaxares died shortly afterwards.

In a fragmentary letter from an Assyrian governor to King Sargera (about 715 B.C.) about rebellions of Median chieftains, a dynast Uvakshatar (i.e. Cyaxares) is mentioned as attacking an Assyrian fortress (Kharkhar, in the chains of the Zagros).

Possibly he was an ancestor of the Median king. (Eo. M.)

CYBELE, or CYBELE (Gr. Κυβέλη, Kýbeta), a goddess native to Asia Minor and worshipped by most of the peoples of the peninsula, was known to the Romans most commonly as the GREAT MOTHER OF THE GODS (g.v.), or the Great Idaean Mother of the Gods—Magna Deum Mater, Mater Deum Magna Idaea. She was known by many other names, such as Mater Idaea, Dindymene, Sipylene, derived from famous seats of worship, and Mountain Mother, &c., in token of her character, but Cybele is the name by which she is most frequently known in literature. Her cult became centered in Phrygia, where it found its way into Greece, where it never flourished greatly, as early as the latter 6th century B.C., and was introduced into the Empire at a very early period, being one of the last pagan cults to die. Cybele was usually worshipped in connexion with Attis (g.v.), as Aphrodite with Adonis, the two being a duality interpreted by the philosophers as symbolic of Mother Earth and her vegetation. (G. S. N.)

CYCLADES, a compact group of islands in the Greek Archipelago, forming a cluster around the island of Syra (Syros), the principal town of which, now officially known as Hermoupolis, is the capital of a department. Population of the group (1907) 130,378. The islands, though seldom visited by foreigners, are for the most part highly interesting and picturesque, notwithstanding their somewhat barren appearance when viewed from the sea; many of them bear traces of the feudal rule of Venetian families in the middle ages, and their inhabitants in general may be regarded as presenting the best type of the Greek race. To the student of antiquity the most interesting are: Delos (g.v.), one of the greatest centres of ancient religious, political and commercial life, where an important series of researches has been carried out by French archaeologists; Melos (g.v.), where, in addition to various buildings of the Hellenic and Roman periods, the large prehistoric stronghold of Phylakopi has been excavated by members of the British school at Athens; and Thera (see SANTORIN), the ancient capital of which has been explored by Baron Hiller von Gaertringen. Thera also is of special interest to geologists owing to its remarkable volcanic phenomena. Naxos, the largest and most fertile island of the group, contains the highest mountain in the Cyclades (Zia, 3390 ft.); the island annually exports upwards of 2000 tons of emery, a state monopoly the proceeds of which are now hypothecated to the foreign debt. The oak woods of Cero (Zeé) and los furnish considerable supplies of valonia. Kimilos, which is absolutely treeless, produces fuller's-earth. The famous marble quarries of Paros have been practically exhausted in modern times; the marble of Thera is now worked by a British syndicate. The mineral wealth of the Cyclades has hitherto been much neglected; iron ore is exported from Scyros, manganese and sulphur from Melos, and volcanic cement (pozzolana) from Santorin. Other articles of export are wine, brandy, hides and tobacco. Cythnos, Melos and other islands possess hot springs with therapeutic qualities.

The island of Santorin, forming an important distributing centre for the whole Levant, has been declining for several years.

Population (1907)—Syra 31,039 (communes, Hermoupolis 18,132, Mykonos 4589, Syra 9218), Anis 18,035 (Anis 8536, Ani 2166, Gaudio 2897, Corinthion 4436); Thera 19,597 (Thera 4226, Egiale 1513, Amorgos 2627, Anaphe 579, Emporion 2172, Therasia 590, Santorin 2639, 1 Nov. 1907, 3827); Dryopis 1628, Cythnos 1563, Seriphus 4024; Melos, 12,774 (Melos 4864, Adamas 529, Siphnos 3777, Kimoles 2015, Pholegandros 962, Sikinos 467)—Naxos 25,185 (Naxos 2064, Apane 2421, Vivlos 4354, Despotiko 225, Ios 1946, 2492, Paros 3586, Thera 4661, Iero 1222; Tenos 11,816 (Teos 4697, Panorme 2658, Perek 201, Soestheni 1660).

CYCLAMEN, in botany, a genus belonging to the natural order Primulacea, containing about ten species native in the mountains of central Europe and the Mediterranean region. C. eurepseum (Sow-bread) is found as an introduced plant in copses in Kent and Sussex. The plants are low-growing herbs with large tuberous rootstocks, from the surface of which spring a number of broad, generally heart-shaped or kidney-shaped, single-stalked leaves, which in cultivated forms are often beautifully marbled, ribbed or splashed. The flowers are nodding, and white, pink, lilac or crimson in colour. The corolla has a short tube and five large reflexed lobes. After flowering the stalk becomes spirally coiled, drawing the fruit down to the soil. Cyclamen is a favourite winter and spring flowering plant. C. persicum is probably the best known. It is a small-growing kind bearing medium-sized leaves and numerous flowers. C. giganteum is a large, strong-growing species; not quite so free flowering as C. persicum, but in all other respects superior to it when well grown. C. papilio differs in the fringed character of the petals. It has been obtained by selection from C. persicum. There is also a very beautiful crested race, probably derived from C. giganteum.

The plants are raised from seed, and, with good cultivation, are soon well established. Seed is sown as soon as ripe, in July or August, in pots or pans, filled up to ¾ in. of the rim with broken crocks for drainage. The soil should consist of fibrous yellow loam, leaf-mould in flake, and coarse silver-sand, in equal parts. Sow the seed thinly—½ in. to ¾ in. apart—and cover with a very thin sprinkling of the soil. Protect with a square of glass covered with a piece of brown paper for shade, and place on a shelf in a warm greenhouse. The soil should never be allowed to dry.

When the seedlings appear, remove the covering, care being taken that they do not suffer for want of shade, water or a moist atmosphere. As soon as the third leaf appears, repot singly into thumb-pots in slightly coarser soil, so that the crowns of the little plants are just above the level of the soil. In December transfer into a little richer soil, consisting of two parts fibrous loam broken into small bits by hand and the fine particles rejected, one part small leaf-mould, passed through a half-inch sieve and one part of potash ash from the burnt refuse heap of another part of coarse silver-sand. Keep through the winter in a moist atmosphere at a temperature not below 50° Fahr., and as near the glass as possible. In March they should be ready for their next shift into 5-in. pots. The potting compost should be the same as for the last shift, with the addition of half a part of well-sweetened manure, such as a spent mushroom bed. Keep in a warm moist atmosphere and shade from strong sunlight. In June remove to cold frames and stand them on inverted pots well clear of one another. Slugs show a marked partiality for the succulent young leaves and should be excluded by dusting round the frames occasionally with newly slaked lime. The inverted pots serve as traps. The frames may thus be frequently syringed without keeping the plants unduly wet. Shade heavily from direct sunlight, but afford as much diffused light as practicable. Ventilate on all favourable occasions, and close the frames early after damp weather.

By the end of the month they will be ready for the final shift into 7-in. pots. Much care must be used in handling them, the leaves being large, tender and numerous. The soil is as for the last potting. The frames should be kept close and heavily shaded.
for a few days after potting; then gradually reduce shade and increase ventilation. By the end of July the elegance of the foliage alone should be repeated if the crown can be thinned. From this time onwards very little shading will be needed, the object of the cultivator being to harden the growth already made. With the advent of cool weather in September, remove to flowering quarters in a warm greenhouse. Flowering will begin in November and will continue through the winter and spring. The damping off of the flower-buds may occasionally prove troublesome during winter. This may generally be traced to checks, such as sudden changes in temperature, too low a temperature, careless watering, &c. During spring plants that are flowering freely will require weak manure water about twice a week.

Plants selected to bear seed should be set aside for that purpose, and as soon as the capsules are found to be developing properly they should be reduced to six or seven per plant, and all flower-buds picked off as soon as they are large enough to handle. The production of strong seeds is of the utmost importance.

Plants grown for market purposes, either for decoration or for seed, are sown later than the above, are kept cooler, and during summer receive more ventilation and less shade. This results in the production of plants with much smaller and more erect leaves, which travel well. They are flowering in spring and early summer.

The species grown for this purpose is C. persicatum.

A few species are hardy in dry sheltered positions, such as rockeries, under walls and old trees, provided the positions are well drained. Such are C. europaeum, with reddish-purple flowers in summer; C. kersleri in autumn; and C. neapolitanum, with large leaves marbled with silver and rosy-pink flowers.

CYCLE (Gr. κύκλος, a circle), in astronomy, a period of time at the end of which some aspect or relation of the heavenly bodies recurs. The more important cycles are discussed in the articles CALENDAR and ECLIPSE. In physics, the term is applied to a series of operations which, performed upon a system, brings it back to its original state; “Carnot’s Cycle” is an example (see THERMODYNAMICS). From the use of the word for any period at the end of which the same events recur in the same order or for any complete series of phenomena, it is used loosely of any long period of time. The name of the Epic Cycle, the epic cycle, was given to the poems which complete the Homeric account of the Trojan War (see below). It is this which has given rise to the application of the term “cycle” to a series of prose or poetical romances which have for a centre one subject, whether a person, as in the Alexander, Arthurian or Charlemagne cycles, or an object, such as the ring of the Nibelungenlied. In music “Song-cycle” (Ger. Liederkreis) is similarly used of a series of songs written round one subject or set to poems by the same author. Beethoven’s An die ferne Geliebte (Op. 98), published in 1816, is the earliest instance. Schubert’s Die schöne Müllerin, Schumann’s Dichterliebe and Brahms’s Magelone-Lieder are well-known instances.

Epic Cycle.—This is a collection or corpus of lays written about 750-580 B.C. by poets of the Ionian School, introductory or complementary to the Homeric poems, dealing with the legends of the Trojan and Theban wars. At a later date they were arranged so as to form a continuous narrative (the Iliad and the Odyssey included), perhaps after certain alterations had been made, to fill up gaps and remove inconsistencies and repetitions. By whom, and when, they were so arranged, cannot be decided; it is possible that it was the work of Zenodotus of Ephesus, who had the care of the epic section of the Alexandrian library. In order to furnish the general reader with a comprehensive sketch of mythological history, Proclus—according to Welcker and Valesius (Valois), not the neo-Platonist, but an unknown 2nd or 3rd century grammarians, perhaps Euthychius Proclus of Sicca in Africa, one of the tutors of Marcus Aurelius (see PROCLUS)—compiled a prose summary (Γενεακαταγωγη) of the contents of the poems, to serve as a sort of primer to Greek literature. Extracts from this are preserved in the Codex Venetus of Homer and Phoebus (cod. 239), according to which the epic cycle was completed and ended with the death of Odysseus on his return to Ithaca at the hands of his son Telegonus. The cycle was in existence in his (Proclus’s) time, and was in request not so much for its artistic merit, as for the “sequence of the events described in it.” Further light is thrown on the subject by pictorial representations, intended for school use during the Roman imperial period, the most famous of which is the Tabula Iliaca in the Capitoline museum.

The expression “epic cycle” in the sense of a poetical collection does not occur before the Christian era; the word κύκλος (“cycle,” “circle”) is used of a special kind of short poem and also of a prose abstract of mythological history; the adjective has the general sense of “hackneyed,” “conventional,” and is applied contemptuously (by Callimachus and Horace) to a particular Alexandrian school of poetry.

The most important poems of the Trojan legendary cycle are the Cypria of Stasinus (q.v.); the Aethiopis and Iliou Persis (Sack of Troy) of Arctinus (q.v.); the Little Iliad of Lesches (q.v.); the Nesti of Hages or Agias; the Teleogonia of Eugammon. To the Theban cycle belong: Thetheos or Expedition of Amphiaras and the Epigoni of Antimachus. The Oeothelais Halos (capture of Oeothelais) of Cephalus (q.v.); the Phoaeis (or Myinia) of Prodicius; and the Danaius of Cercops, although belonging to the old Homeric epoch, cannot with certainty be included in the epic cycle. The names of the authors are in several cases exceedingly doubtful.

Bibliography.—The standard work on the subject is F. G. Welcker, Der epochale Cyclus (1865-1882); see also T. W. Allen, “The Epic Cycle,” in Classical Quarterly, Jan. and April 1908 (summary of sources and authorities); Wilamowitz-Molêndorff, Homerische Untersuchungen (1884), who regards the traditional materials as representing the opinions of the schools of ancient criticism; D. B. Monro, Journal of Hellenic Studies, iv. (1885), appendix to his edition of the Odyssey, xii.-xxiv. (1900), and on the Codex Venetus fragment of Proclus; J. E. Sandys, Hist. of Class. Schol. (2nd ed., 1908), ch. i. (1903); E. Magurier, “Les cycles mythologiques de l’Antiquité,” in Bulletin de l’Académie de Dijon, xxiv. (1901), pp. 1-48. The cycle is also treated in the articles CYCLING and POETICAL CYCLES.

CYCLING, the clipped term now given comprehensively to the sport or exercise of riding a bicycle (q.v.) or tricycle (q.v.).

Suggestions of vehicles having two or more wheels and propelled by the muscular effort of the rider or riders are to be found in very early times, even on the bas-reliefs of Egypt and Babylonia and the frescoes of Pompeii; but the modern process, as exemplified by such contrivances as were recorded in the 17th and 18th centuries, it was apparently not until the beginning of the 19th century that they were used to any considerable extent. A “velocipede” invented by Blanchard and Magurier, and described in the Journal de Paris on the 27th of July 1779, differed little from the celerite proposed by another Frenchman, de Sivrac, in 1690; it consisted of a wooden bar rigidly connecting two wheels placed one in front of the other, and was propelled by the rider, seated astride the bar, pushing against the ground with his feet. The next advance was made in the draisine or Freiherr Carl Draiss of Sauerbronn (1785-1851), described in his Abbildung und Beschreibung seiner neu erfundenen Lauflmaschine (Nuremberg, 1817). In this the front wheel was pivoted on the frame so that it could be turned sideways by a handle, thus serving to steer the machine (figs. 1 and 2). A similar machine, the “celeripeze,” also with a movable front wheel, is said to have been ridden by J. N. Niepce in Paris some years before. In England the draisine achieved a great, though temporary, vogue under various names, such as velocipede, patent accelerator, bivector, biciped, pedestrian curricule (patented by Dennis Johnson in 1818), dandy horse, hobby horse, &c., and for a time it was popular in America also. The propulsion of the draisine by pushing with the feet being alleged to give rise to diseases of the legs, arrangements were soon suggested, as by Louis Gompertz in England in 1821, by which the front wheel could be rotated by the hands with the aid of a system.
of gearing, but the idea of providing mechanical connexions between the feet and the wheels was apparently not thought of till later. Pedals with connecting rods working on the rear axle are said to have been applied to a tricycle in 1834 by Kirkpatrick McMillan, a Scottish blacksmith of Keir, Dunfrieshire, and to a draisine by him in 1840, and by a Scottish cooper, Gavin Dalzell, of Lesmahagow, Lanarkshire, about 1845. The draisine thus fitted had wooden wheels, with iron tires, the leading one about 30 in. in diameter and the driving one about 40 in., and thus it formed the prototype, though not the ancestor, of the modern rear-driven safety bicycle.

For the next 20 years little was done, and then began the evolution of the high "ordinary" bicycle with a large driving wheel in front and a small trailing one behind. About 1865 Pierre Lallement in Paris constructed a bicycle in which the front wheel was driven by pedals and cranks attached directly to its axle, but it is doubtful whether the origin of this idea must be attributed to him or to Ernest Michaux, the son of his employer, who was a carriage repairer. Lallement took his machine to the United States, and in 1866 it was granted a patent which had an important influence on the subsequent course of the cycle industry in that country. This machine, consisting of a wooden frame supported on two wooden wheels (fig. 3), soon became popular in England, as well as in France and America, and came to be called bicycle (or byscyle) by those who took it seriously and "boneshaker" by those who did not. Improvements quickly followed, chiefly in England, for in America the popularity of the machine was short-lived, and in France the industry was checked by the Franco-German war. Rubber tires, in place of iron ones, appeared in 1868, and in two or three years were made very large, 2 in. or more in width. Suspension wheels, with wire spokes in tension, were seen at the Crystal Palace, London, on the "Phantom" (fig. 4) of W. F. Reynolds and J. A. Mays in 1869, and early in the same year the manufacture of bicycles, at first for export to France, was begun in England by the Coventry Sewing Machine Company, till then makers of sewing machines. There was a rapid growth in the size of the front wheel, which in the boneshaker normally measured 36 or 38 in. in diameter, with a corresponding shrinkage in the rear wheel (fig. 3), until by 1874, the date of the invention of the tangent wheel by J. K. Starley 54-in. wheels were being made. The high bicycle was now fairly established in form, and the changes made in the subsequent 10 or 15 years during which it retained its supremacy were chiefly in the details of construction, such as the adoption of steel tubing for the frames, the use of hollow rims in the wheels and the application first of cone and then of ball bearings to points of friction. The weight of a 54-in. bicycle, which in 1874-1875 exceeded 50 or even 60 lb, was thus reduced to well under 40 lb in machines intended for use on ordinary roads, and to not much over 20 lb in the case of racers.

The high "ordinary" bicycle (fig. 6) gave unquestionable pleasure to many riders, and very fast times were made with it both on the road and on the racing path. In 1882 H. L. Cortis rode 20 m. 300 yds. in one hour, and in April 1884 Thomas Stevens started from San Francisco to ride round the world, a feat which he accomplished in December 1886. But it had various disadvantages. The vibration set up by the small back wheel was very trying, and in spite of the size of the front one the rider had to move his pedals at an uncomfortably rapid rate if he wished to maintain a good speed. Moreover his seat was placed in such a position that he was liable to be pitched over the handlebar if his wheel encountered a comparatively small obstacle. Attempts were made to remedy these inconveniences in various ways. From the early 'eighties much attention was devoted to tricycles, and these were produced in innumerable designs, whether for a single rider, or for two in the form of "sociables," or thrones or "tandems," in which the riders sat side by side, or of "sociables," in which one sat behind the other. But their weight, and consequently the exertion of propelling them, was necessarily greater than in the case of the bicycle, and by the end of the decade, the demand for them had fallen off, though they are still made to a certain extent, chiefly for carrying purposes. The two-track bicycle (fig. 7), invented by E. C. F. Otto about 1879, in which the rider balanced himself between two equal wheels placed abreast, also failed to secure lasting success.

The improvement of the high bicycle was attempted in two directions. On the one hand it was modified by placing the rider farther back, his position "over his work" being ensured by arranging the pedals immediately below him and connecting them to the front wheel, which was usually reduced in size, by levers and cranks or by chain-gearing, often with a multiplying action. On the other, the rear wheel was enlarged and made the driving wheel. The "Xtrordinary" (fig. 8), "Facile" (fig. 9) and "Kangaroo" were examples of the former kind, which were often spoken of as "dwarfsafeties"; but though a good many of them were used about 1885 and following years, both they and the "ordinary" bicycle ultimately disappeared before machines of the second kind, which developed into the modern rear-driven safety. There are numerous claimants for the invention—or rather the reinvention—of this type,
but it appears that the credit for its practical and commercial introduction in substantially its present form is due to J. K. Starley in England. His "Rover" (fig. 10), brought out late in 1885, had two nearly equal wheels, the driving wheel 30 in. in diameter and the steering 32 in., and the rider sat so far back that he could not be thrown forward over the handles. The motion imparted by the pedals to a sprocket wheel mounted between the wheels was transmitted by an endless chain to the rear wheel, and by sufficiently increasing the size of this sprocket wheel the machine could be made to travel as far or farther than the "ordinary" for each complete revolution of the pedals. From about 1890 the "safety" monopolized the field. At first it was fitted with the narrow rubber tires customary at the time, but these gave way to pneumatic tires, invented in 1888 by J. B. Dunlop, a veterinary surgeon of Belfast, whose idea, however, had been anticipated in the English patent taken out by R. W. Thomson in 1845. The result was a great gain in comfort, due to reduction of vibration, and a remarkable increase of speed or, alternatively, decrease of exertion. Subsequent progress was mainly in the details of design and manufacture, tending to secure lightness combined with adequate strength, and such was the success attained, by the application of scientific principles and of improved methods and materials to the construction of the frames and other parts, that while the weight of the original "Rover" was about 50 lb, that of its successors 20 years later with 28-in. wheels was reduced by 35 or 45% or even 60% in the case of racing machines. The beginning of the 20th century saw the introduction of two innovations: one was the "free-wheel," a device which allows the driving wheel to rotate independently of the chain and pedals, so that the rider, controlling his speed with powerful brakes, can "coast" down a hill using the stationary pedals as foot-rests; and the other was the motor-cycle, in which a petrol-engine relieves him, except at starting, from all personal exertion, though at the cost of considerable vibration. A third contrivance, which, however, was an idea of considerably older date, also began to find favour about the same period in the shape of two-speed and three-speed gears, enabling the rider at will to alter the ratio between the speed of revolution of his pedals and of his driving wheel, and thereby accommodate himself to the varying gradients of the road he is traversing. (See also Bicycle, Tricycle and Trike.)

The safety bicycle, with pneumatic tires, rendered cycling universally popular, not merely as a pastime but as a convenient means of locomotion for everyday use. Made with a drop-frame, it also enabled women to cycle without being confined to a heavy tricycle or compelled to assume "rational dress." In consequence there was an enormous expansion in the cycle industry. In England the demand for machines had become so great by 1895 that the makers were unable to cope with it. Numbers of new factories were started, small shops grew into large companies, and the capital invested advanced by millions of pounds. The makers who had devoted their mechanical skill to perfecting the methods of cycle-construction were swallowed up by company promoters and adventurers, bent simply upon filling their own pockets. The march of mechanical invention and improvement was arrested, and machines, instead of being built by mechanics proud of their work, in many cases were merely put together in the shortest possible time and in a few standard patterns. For these the world clamoured, and for a year they could not be produced fast enough. Then the demand fell off, the British market became over-stocked, and as the British makers declined to consider the wants of foreign customers, their store-rooms remained crowded with machines that could not be sold. Speculative finance, such as was exemplified in 1896 by the flotation for £5,000,000 of the Dunlop tire company, which had been started in 1889 with a capital of £25,000, had its natural effects. There ensued widespread and continuing disorganization of the trade, which had to be met by extensive reconstructions of over-capitalized companies. English makers too had lost the commanding international position they once enjoyed, when they supplied almost the entire demand for bicycles in many parts of the world, including the United States. In America the manufacture of bicycles was not begun until about 1878, when it was introduced by A. A. Pope (1843-1900), and even by 1890 the value of the products barely exceeded 2½ million dollars, while for several years later much of the steel tubing required for bicycle manufacture continued to be imported from Great Britain. The industry, however, thanks to automatic machinery and perfect organization, grew rapidly, and in 1900 the value of its products was nearly 32 million dollars. In the two years 1897 and 1898 the exports of cycles and cycle parts alone were worth nearly 14 million dollars, though they fell off in subsequent years, and English makers had to contend with an American invasion in addition to their domestic troubles. The competition was short-lived. The American makers sent over machines with single tube tires and wooden rims which did not secure the approval of the British purchaser, and so they too lost their hold. In the opening years of the 20th century the industry in Great Britain gradually recovered itself. More attention was paid to the production of cheap machines which were sound and trustworthy, and sales were further stimulated by the introduction of systems of deferred payments. In 1905 about 600,000 machines were made in Great Britain, and 47,604 were exported, the total value of the home-market for cycles and their parts being about 3½ millions sterling, and of the export trade about one million. In the same year the number of machines imported was only 3245.

Cycle tours were taken and cycle clubs established almost as soon as the cycle appeared, the Pickwick Bicycle Club in London, founded in 1870, being the oldest in the world. The organization of these clubs is chiefly of a social character, and a few possess well-appointed club-houses. To a great extent they have been superseded by the large touring organizations. The Cyclists' Touring Club, organized in 1878 as the Bicycle Touring Club, has members scattered through Europe, America and even the East. Many other countries possess national clubs, as for instance the League of American Wheelmen, founded in 1880, and the Touring Club de France, founded in 1895, of whose objects cycling is only one, though the chief. The aim of these national associations, which have formed an international touring league, is the promotion of cycle touring. To this end they publish road-books, maps and journals; they recommend hotels, with fixed tariffs, in their own and other countries; they appoint representatives to aid their members when touring; and they have succeeded in inducing most governments to allow their members to travel freely across frontiers without paying duty on their machines. In all countries they have erected warning-boards at dangerous places; in France the best route is suggested by a sign-post, and cyclists who meet with accidents in lonely places find repair outfits provided for their free use. Another important part of the work of these clubs, either directly or indirectly, is the improvement of the roads. France has done more for the cyclist than any other country, owing to the fact
CYCLOID in less than a minute in the autumn of 1900. Other cyclists have devoted themselves, at the instigation of makers, to the riding of 100 m. a day every day for a year. It would be difficult to say what advantage there is in these trials and contests. They are not convincing records, and only prove that some people are willing to take great personal risks for the benefit of their employers. E. Hale, during 1899-1900, covered 32,406 m. in 313 days. For many years also long-distance races, mostly of six days' duration, have been promoted on covered tracks, and though condemned by all cycling organizations, they find a great deal of pecuniary support.

The cycle has also been taken up for military purposes. For this idea the British army is indebted to Colonel A. R. Savile, who in 1887 organized the first series of cycle manoeuvres in England. Since then military cycling has undergone a great development, not only in the country of its origin but in most others.

Cycling has produced a literature of its own, both of the pastime and of the trade. Owing to the enormous profits which, for several years, accrued to the manufacturers of bicycles, and to the large membership, their publications were composed of clubs and not individuals. Among the most important are the National Cyclists' Union of England and the Union Vélocipédique of France. These bodies are also bound together by the International Cyclists' Association, which is devoted mainly to the promotion of racing and legislation connected with it all over the world.

The National Cyclists' Union, originally the Bicycle Union, which was the parent body of all, formed in February 1878, was the first to put up danger-boards, and also was early instrumental, alone and with the C.T.C., in framing or suggesting laws for the proper government and regulation of cycle traffic, notably in establishing its position as a vehicle in securing universal rights, in endeavouring, again in conjunction with the C.T.C., to increase facilities for the carriage of cycles on the railways, in securing the opening of parks, and in promoting many other equally praiseworthy objects. For a number of years, however, it has been more prominent as the ruling race-governing body. But cycle racing has fallen upon evil days. At one time cycle racing attracted a large number of spectators. But it has now fallen into disfavour, or rather was ignored by the public because it became mainly an advertisement for cycle makers. The presence of the man, directly or indirectly, in the employ of, or aided by a maker, and the consequent mixing up of trade and sport, lowered racing not only in the public estimation, but in that of all genuine amateurs. There have always been a few amateurs who have raced for the love of the sport, but the greater number of prominent racing men have raced for the benefit of a firm, so much so that, at one time, an entire section of racing men were classed as "makers' amateurs." They did not confine themselves to the race track, but appropriated the public roads until they became a danger and a nuisance, and road-racing finally was abolished, though record rides, as they are called, are still indulged in, being winked at by the police and by the cycling authorities. The makers' amateurs at least rode to win and to make the best time possible. But the scandal was so great that a system of licensing riders was quickly adopted by the N.C.U., and if this did not effectively kill the sport, the introduction of waiting rules did. There probably is considerable skill in riding two-thirds of a race as slowly as possible, and only hurrying the last part of the last lap, but it does not amuse the public, who want to see a fast race as well as a close finish. The introduction of pacing by multicycles and motors next took from cycle racing what interest was left. A motor race, in which the machines are run at top speed, is more exciting than the spectacle of a motor being driven at a rate which the cyclist can follow with the protection of a wind-shield.

In America this system of proving what cyclists can do with racing machines was carried so far that in 1890 a board track was laid down on the Long Island railway for about 2 m. between the metals, and a cyclist named Murphy, followed a train, and protected by enormous wind-shields, succeeded in covering a mile.
its centre of gravity, and Pierre Fermat deduced the surface of the spindle generated by its revolution. A famous period in the history of the cycloid is marked by a bitter controversy which sprung up between Descartes and Roberval. The evaluation of the area of the curve had made Roberval famous in France, but Descartes considered that the value of his investigation had been grossly exaggerated: he declared the problem to be of an elementary nature and submitted a short and simple solution. At the same time he challenged Roberval and Fermat to construct the tangent; Roberval failed but Fermat succeeded. This problem was solved independently by Vivencio Viviani in Italy. The cartesian equation was first given by Wilhelm Gottfried Leibnitz (Acta eruditorum, 1686) in the form \( y = \frac{1}{c}(x^2 - c^2) \). Among other early writers on the cycloid were Wallis, Roberval, and Nicolle (1633-1758).

The mechanical properties of the cycloid were investigated by Christian Huygens, who proved the curve to be tautochronous. His inquiries into evolutes enabled him to prove that the evolute of a cycloid was an equal cycloid, and by utilizing the fact it was the basis of the isochron pendulum generally known as the cycloidal pendulum. Huygens proposed the famous problem of the brachystochrone (see Mechanics), and it was proved by Leibnitz, Newton and several others that the cycloid was the required curve.

The method by which the cycloid is generated shows that it consists of an infinite number of cusps placed along the fixed line and separated by a constant distance equal to the circumference of the rolling circle. The name cycloid is usually restricted to the part of the curve above the base or the fixed line LM; the fixed line LM is termed the base, and the line PQ, which divides the curve symmetrically, is the axis. The co-ordinates of any point P on the curve can be expressed in the form \( x = a(\theta + \sin \theta) \), \( y = a(1 - \cos \theta) \), where the co-ordinate axes are the tangent at the vertex O and the axis of the curve. The radius of the generating circle, and \( \theta \) the angle R'OC, where RR' is parallel to LM and C is the centre of the circle in its symmetric position. Eliminating \( \theta \) between these two relations the equation is obtained in the form \( x^2 + y^2 = 2ax \cos \theta \). The clumsiness of the relation renders it practically useless, and the two separate relations in terms of a single parameter \( \theta \) suffice for the deduction of most of the properties of the curve. The length of any arc may be determined by the methods of integrated calculus. When measured from the vertex the results may be expressed in the forms \( s = 4a \sin \frac{\theta}{2} \) and \( s = (8a) \sin \frac{\theta}{2} \); the total length of the curve is \( 8a \).

The equation of the evolute is \( s = 4a \cos \theta \), and the equation to the evolute is \( s = 4a \cos \theta \), which proves the evolute to be a similar cycloid placed as in fig. 2, in which \( x = a(\theta + \sin \theta) \) and \( y = a(1 - \cos \theta) \).

The radius of curvature at any point is readily deduced from the intrinsic equation and the value \( s = a \cos \theta \) is equal to twice the normal which is \( 2a \cos \theta \).

The trochoids were studied by Torricelli and F. van Schooten, and more completely by John Wallis, who showed that they possessed properties similar to those of the common cycloid. The cartesian equation of the trochoids is similar to those used above is \( x = a(\theta + \sin \theta) \), \( y = a(1 - \cos \theta) \), where a is the radius of the generating circle and \( \theta \) the distance of the carried point from the centre of the circle. If the point is without the circle, i.e. if \( a > b \), then the curve exhibits a succession of nodes or loops (fig. 3). When the circle, i.e. if \( a < b \), the curve has the form shown in fig. 1, curve c.

The companion to the cycloid is a curve so named on account of its similarity of construction, form and equation to the common cycloid. It is generated as follows: Let ABC be a circle having AB for a diameter. Draw any line DPE perpendicular to AB and meeting the circle in E, and take the point P on DPE such that AE = AB; then the locus of P is the companion to the cycloid. The curve is shown in fig. 3. The cartesian equation, referred to the fixed diameter AB and the tangent at B as axes may be expressed in the forms \( x = a\theta \), \( y = a(1 - \cos \theta) \); the latter relation shows that the locus is the harmonic curve.

For epicycloids and hypocycloids see EPICYCLOID.

References.—Geometrical constructions relating to the curves above described are to be found in T. H. Eagles, Constructive Geometry of Plane Curves. For the mechanical and analytical investigation, reference may be made to articles MECHANICS and INFINITE SELL CULCULUS. A historical bibliography of these curves is given in Bonard, Notes de bibliographie des courbes géométriques (1697). See also Moritz Cantor, Geschichte der Mathematik (1864-1901).

Cyclocycle (Gr. κυκλοκύλος, circle, and μέτρων, measure), an instrument used especially by cyclists to determine the distance they have traversed. In a common form a stud attached to one spoke of the wheel engages with a toothed pinion and moves it on one tooth at each revolution. The pinion is connected with a train of clockwork, the gearing of which bears such a ratio to the circumference of the wheel that the distance corresponding to the number of times it has revolved is shown on a dial in miles or other units.

Cyclone (Gr. κυκλων, whirl, from κυκλος, a circle), an atmospheric system where the pressure is lowest at the centre. The winds in consequence tend to blow towards the centre, but being diverted according to Ferrel's law they rotate spirally inwards at the surface of the earth in a direction contrary to that of the movement of the body of the watch in the northern hemisphere, and the reverse in the southern hemisphere. The whole system has a motion of translation, being generally carried forward with the great wind-drifts like eddies upon a swift stream. Their direction of movement over the British Islands is usually from S.W. to N.E., though they may remain stationary or move in other directions. The strength of the winds depends upon the atmospheric gradients. (See Meteorology.)

Cyclopean Masonry (from the Cyclopes, the supposed builders of the walls of Mycenae), a term in architecture, used, in conjunction with Pelasgic, to define the rude polygonal construction employed by the Greeks and the Etruscans in the walls of their cities. In the earliest examples they consist only of huge masses of rock, of irregular shape, piled one on the other and trusting to their great size and weight for cohesion; sometimes smaller pieces of rock filled up the interstices. The walls and gates of Tiryns and Mycenae were thus constructed. Later, these blocks were rudely shaped to fit one another. It is not possible to decide the period by the type of construction, as this depended on the material; where stratified rocks could be obtained, horizontal courting might be adopted; in fact, there are instances in Greece, where a later wall of cyclopean construction has been built over one with horizontal courses.

Cyclopæan Masonry, the round-eyed, plural of Cyclops), a type of beings variously described in Greek mythology. In Homer they are gigantic cave-dwellers, cannibals having only one eye, living a pastoral life in the far west (Sicily), ignorant of law and order, fearing neither gods nor men. The most prominent among them was Polyphemus. In Hesiod (Theogony, 264) they are the three sons of Uranus and Gaea—Brontes, Sterope and Argus,—storm-gods belonging to the family of the Titans, who furnished Zeus with thunder and lightning out of gratitude for having released them from Tartarus. They were slain by Apollo for having forged the thunderbolt with which Zeus slew Asclepius. Later legend transferred their abode to Mt Aetna, the Lipari islands or Lemnos, where they assisted Hephaestus at his forge.

A class of Cyclopes are the builders of the so-called "Cyclopean" walls of Mycenae and Tiryns, giants with arms in their belly, who were said to have been brought by Proetus from Lycia to Argos, his original home (Pausanias ii. 16. 5; 25. 8). Like the Curetes and Telchines they are mythical types of pre-historic workers and architects, and as such the objects of worship.

The standard work on these and similar mythological characters is M. Mayer, Die Giganten und Titanen (1887); see also A. Boltz, Die Titanen und Giganten (1880), who endeavours to show that they were an historical people; J. H. Hạnhsen, The Old and the Poli balancing (1904); J. E. Harrison, Myths of the Odyssey (1882); and article in Roscich's Lexikon der Mythologie (bibliography).

Cyclostomata, or Marsipobranchii, a group of fishes including the ordinary lampreys and hagfish, and so called from the wide permanently gaping mouth which is usually the hinged jaws characteristic of other vertebrates (Gnatostomata).
The class Cyclostomata consists of two orders, the Myxinoids (or Hyperotreti) and the Petromyzontes (or Hyperarti), which, while showing sufficient resemblance in structure to warrant their inclusion in the same class, are yet marked off by such deep-seated differences as to indicate that they commenced to diverge from one another far back in evolutionary time. The order Myxinoids includes the hagfish (Myxine), common off the eastern, and occurring also, though less commonly, off the western coasts of the north Atlantic, and the genus 

Petromyzon (also known as 

Hemidactylium, Eptatretus, in part — Polistotrema), including the "borders" of the western American coast, New Zealand and the Cape of Good Hope. The order Petromyzontes includes the widely distributed lampreys. The original genus Petromyzon (which it is now customary to subdivide into a number of genera) includes the large sea lamprey (P. marinus) of the north Atlantic and the two fresh-water lampreys of European streams (P. fluviatilis and P. planeri, the latter of which is possibly only a small-sized variety of the former species). In North America nine or ten species of lampreys are known to occur, descriptions of which are given by Jordan and Evermann (1). In the southern hemisphere occur the two genera 

Mordacia (Chile, Tasmania) and 

Geotria (Chile, Australia, New Zealand) (2).

The Myxinoids are remarkable in that they are semiparasitic in habit. The lampreys — except some of the small fresh-water forms — attach themselves to other fishes by their suckorial mouth and proceed to rasp off the flesh by means of the horny teeth carried by the highly-developed tongue. The Myxinoids have gone a step further and actually bore their way into the body of their prey, devouring all the soft parts and leaving the skin behind as a mere shell, empty but for the bones. Where the hagfish or borers are abundant, as in certain localities off the east coast of Scotland and off the west coast of California, they may do great damage to fisheries from their habit of attacking fishes which are in difficulties through being caught by a hook or in a net; the fish when drawn up being frequently completely deprived of their flesh.

The Myxinoids retain the ancestral marine habitat, but the lampreys have sought refuge from the struggle for existence by taking to fresh water to a less or greater extent. Such a form as Petromyzon marinus or Enchelyopus tridentatus of the west coast of America is what is known as anadromous in habit, i.e. it takes to the sea for the purpose of spawning. Certain species of lampreys, on the other hand, have completely deserted the sea and spend their whole lives in fresh-water streams or lakes. The lake lampreys show a resemblance of their ancestral migratory habits in leaving lakes and ascending streams in order to deposit their spawn.

Anatomy.—In structural features, the Cyclostomes show a curious mixture of features which must be looked on as primitive with others which are indicative of high specialization for their peculiar mode of life. In general appearance they are "eel-like"; they are elongated in shape and adapted for swimming in eel fashion, i.e. the body is propelled forward by the backward passage along it of waves of lateral flexure. There are, however, certain conspicuous differences which at once serve to distinguish a Cyclosteom from any other fishes of eel-like shape:

(1) The circular permanently open mouth, (2) the absence of all trace of paired limbs, (3) the absence of paired external nasal openings, and (4) the presence on the roof or at the tip of the head of a single median opening in the pituitary opening.

It will be convenient, in describing the remarkable features of the group, to take as a basis for the description the marine lamprey, Petromyzon marinus. A marine lamprey is an eel-like creature 70 to 75 cm. in length. At the anterior end and situated somewhat ventrally is the circular widely gaping mouth or buccal cavity, its lining studded with sharply pointed "teeth" and its edge fringed with numerous sensory papillae. On the dorsal side of the head is the conspicuous circular pituitary opening with prominent lips, while on the sides are seen the eyes, and behind these a row of somewhat rounded branchial openings or gill-slits. At about the beginning of the posterior fourth of the body, and in the midventral line, is the anal opening, and immediately behind it is the prominent papilla carrying the opening of the urogenital sinus. The hinder portion of the body, in accordance with its function in locomotion, is flattened from side to side, while its surface is increased by the development of a median fin fold, divided, except in early stages of development, into three portions, known as the first and second dorsal fins and the caudal fin. The last mentioned is of the primitive protocercal type. The whole surface of the body — which shows a conspicuous dark marbling, especially dorsally, on a light ground — is covered with highly glandular epidermis. An important feature is the complete absence of all trace of the classified phacid plates which are so characteristic of the Elasmobranchii.

The Myxinoids differ from the lampreys in regard to several of the above-mentioned characters. The edges of the mouth carry tentacle-like barbels. The pituitary opening is close to the anterior edge of the mouth opening instead of being remote from the dorsal side of the head. The eyes are invisible, being greatly reduced and sunk far below the surface, and in Myxine, though not in Bdelostoma, the row of gill openings is represented by a single opening on each side of the head. The midventral line remains, however, at the about the end of the first quarter of the body length. Ventrally the Myxine possesses on each side of the body a row of remarkable epidermal glands which can produce at will enormous quantities of glutinous mucus. This secretion, which on discharge from the mouth opening, is attacked by the ever-increasing number of fish with hooked teeth, is converted into very fine threads, formed by the production of the protoplasms of certain cells of the epidermal glands ("thread cells") into an extremely fine, tightly coiled filament, which, by the peculiar habit of the species of retaining the thread in the gill cavities, is a sufficient protection from attack, is composed of very fine threads, formed by the conversion of the protoplasms of certain cells of the epidermal glands ("thread cells") into an extremely fine, tightly coiled filament, which, by the peculiar habit of the species of retaining the thread in the gill cavities, is a sufficient protection from attack.

Pituitary Tube.—A remarkable peculiarity of the Cyclostomes lies in the fact that the pituitary ingrowth of ecdyterum does not, as in other forms, become involved in the impinging of ecdyterum

Cyclostomata

From D. Starr Jordan, A Guide to the Study of Fishes, by permission of A. Constable & Co. Ltd.

FIG. 1.—The Marine Lamprey (Petromyzon marinus, L.), which forms the buccal cavity.

On the contrary, it lies outside the edge of the stomodeum and in the case of this lamprey the growth takes place in the tissue between the pituitary and stomodeal ingrowths, so that the two openings come to be widely separated, the pituitary opening being pushed back on to the dorsal side of the head. The pituitary opening remains patent throughout life, as is the case with Crossopterygians alone amongst Gnathostomata. In Myxine a further remarkable peculiarity in regard to the hypophysis, probably adaptive in nature, occurs, inasmuch as the pituitary ingrowth developing opens an opening at its posterior end into the pharynx.

Nervous System.—The anterior end of the nervous tube is enlarged and differentiated to form a brain as in other Vertebrates, but this brain to the lampreys at least shows remarkably primitive features. The enlargement as compared with the spinal cord is seen to be comparatively slight: the brain is much elongated, and its various regions lie in a straight line one behind the other; the roof of the brain retains to a great extent the primitive epithelial condition. On each side anteriorly there is the olfactory region, composed of a single epithelial row, and this is continued posteriorly into a small cerebral hemisphere.

The lampreys are amongst those vertebrates in which there is an eel-like apparatus (3) connected with the roof of the thalamencephalon by a bridge of nerve tissue which escapes from the thalamencephalon as two processes, a posterior (the pineal process), and an anterior (the parapineal process). The pineal process grows forwards so as to overlie the parapineal process. Each of these projections from the roof of the thalamencephalon, as they lie, is a patchy, differentiated nervous tissue which is known as a vesicle shows certain eye-like characteristics, its deep wall forming a "retina" and its superficial wall being clear and translucent ("pellucida"). The retinal cells are packed in the case of the pineal organ with large rods; the parapineal organ has a very small number of rods but a much larger number of conical elements. Definite sensory cells are also present with rod-like structures projecting into the lumen of the vesicle. Nerve fibres have been traced — from the pineal organ into the parapineal organs. The large rods are therefore connected with the spinal cord, and it differs from that of the lampreys by being relatively much shorter in an anteroposterior direction. A remarkable negative feature lies in the complete absence of the pineal and parapineal organs so conspicuous in the lampreys. The olfactory organ of Cyclostomes is remarkable for two special characteristics, firstly, that the two olfactory organs of other vertebrates are here represented by a single median structure, and secondly,
that the olfactory organ becomes sunk down beneath the surface through becoming involved in the ectodermal ingrowth which forms the pituitary tube. As a further consequence in the case of the lampreys the olfactory organ becomes transported to the roof of the head along with the pituitary opening, which latter functions as a nasal orifice. That the expanded olfactory organ of existing Cyclostomes has passed through, in their ancestors, a paired condition such as exists in other vertebrates, is indicated by the fact that it retains a pair of olfactory nerves.

The eyes in adult lampreys are of moderate size, while in the Myxinoidea they are greatly reduced—sunk beneath the skin (Bdellostoma) or even in amongst the muscles of the head (Myxine). The lens is completely absent, also the ocular muscles. The otocyst or auditory organ is a unique amongst cranial vertebrae in regard to its subdivision into the semicircular canals. In the lampreys there are only two instead of the normal three, while the Myxinoidea have only one.

**Alimentary Canal.**—The widely gaping buccal funnel is morphologically analogous to the pharynx opening, while, i.e., it is stomodeal in nature. The horn-like teeth which stud its lining are formed simply by concretion of the epidermal cells (4) like the provisional horny teeth of a tadpole, and are not homologous with the true teeth of ordinary vertebrates. As to whether they represent the remnants of an ancient once present system of epidermal scales, indeed may have preceded the covering of placoid elements in the evolution of the vertebrate, there is no evidence.

The pharyngeal region, closely associated with the respiratory function, possesses on each side, series of gill-sacs (six in Myxine; seven in Petromyzon, besides an anterior one which is laid down in the embryo but disappears later; up to as many as fourteen in Bdellostoma) opening on the one hand to the pharynx and on the other to the exterior. In Bdellostoma and in the larva of Petromyzon.

Modified from T. J. Parker, Zoology, fig. 4, by permission of Macmillan & Co., Ltd.

**FIG. 2.**—Median longitudinal section through anterior end of Petromyzon.

br. Brain.

d.a. Dorsal aorta.

i.j.v. Inferior jugular vein. v. Ventricle.

n. Notochord.

The gill-sacs open directly from the pharynx to the exterior, but in the adult lamprey and in *Myxine* the original relations are modified. In *Myxine*, the external openings of the gill-sacs have migrated backwards along the side of the body and become coincident at a point slightly posterior to the last sac. It follows from this that each sac is connected with the common aperture by a tube, longest in the case of the first sac, shortest in the case of the last. In the adult lamprey a different modification is found. Here the dorsal portion of the pharynx has become pinched off as a nake-shaped organ which functions as an oesophagus from the larger ventral portion, which forms an elongated saccular structure ending blindly at its hinder end and having in its lateral wall the internal openings of the gill-sacs.

**Breathing.**—The inspiratory current passes inwards by the mouth opening in the larval lamprey, by the pituitary tube in *Myxine*, while in the adult lamprey both expiration and inspiration takes place through the external gill openings. In the larval lampreys the branchial regions, i.e., the lateral gill-lattices of the branchial region (see below) play an important part in respiration. The branchial region shows rhythmic contraction through the agency of the transverse muscles—expansion, through the elasticity of the branchial skeleton—in the adult lamprey. These rhythmic movements of the branchial region cause successive inflow and outflow through the branchial openings. In the larva, on the other hand, the respiratory current always passes in one direction—backwards. This is helped by the presence of a velar fold at the front end of the pharynx, which acts as a valve, opening only backwards, and to the presence of membranous flaps projecting back from the anterior border of each gill-opening and acting as valves which open only outwards.

The blood passes forward into the digestive tract as the alimentary canal in the form of a straight tube showing little differentiation into special regions. The lining of the intestine is increased in area by an inwardly projecting fold, which is compared by some morphologists with the spiral valve of certain other groups. In the mature river lamprey the digestive tract becomes in great part degenerate.

**Coelom.**—The chief point of interest about the splanchnocoelic or perivisceral cavity is that in the Myxinoidea the adult shows a persistent embryonic condition in that the pericardiac portion normally isolated from the main body cavity.

The renal organs are of special interest in the Myxinoidea from their very simple character. The kidney duct is seen running along the roof of the coelom on either side. Into the duct open short tubules, which, on account of the arrangement of the turbinate ridge, may be readily identified as Malpighian bodies. Each of these short tubes is morphologically a nephric tubule, which, however, in correlation with its shortness, is without the turns and twists so characteristic of such tubules in adult vertebrates. The characteristic feature of the tubules is that they are quite separate from one another, instead of being massed together to form a compact gland such as the kidney is elsewhere. In *Petromyzon* the kidney has the appearance of a series of sinuses, according to which here also the Malpighian bodies are shut off from the splanchnocoel.

The ovary or testis is a large unpaired structure hanging from the dorsal wall of the splanchnocoel and shedding its products into it; from the coelomic space the genital products pass into the urogenital sinus formed by the fusion of the kidney ducts at their hinder ends, and through a small opening, one at each side. This opening, which leads directly from coelom into urogenital sinus, is known as the genital pore. Its morphological significance is doubtful.

**Blanchial Basket.**—One of the most characteristic features of the skeleton of the lamprey is the "blanchial basket," which supports the gill region. In an adult river lamprey the basketwork consists on each side of a series of eight vertical half-hoops of cartilage. The hoops of each side are connected together dorally by a pair of longitudinal bars, lying ventral to the ventral grooves. Connected with the basketwork posteriorly is a remarkable cup-shaped cartilage, which supports the hind wall of the pericardium. The series of cartilaginous half-hoops naturally suggest the form of a chain or series of small interlocking orifices. The relation of these to the vascular orifices of the larva, there are a number of other cartilaginous pieces present in the head region, the homologies of which are doubtful.

**Vascular System.**—The heart (5) of the lamprey consists of an atrium and a single ventricle, the atrium on the left, the ventricle on the right. Into the atrium, on its right side, and behind the atrio-ventricular opening, there opens a nearly vertical chamber usually termed the sinus venosus (see below), the opening guarded by a pair of vertically placed valves. The ventricle passes anteriorly into what is clearly the homologue of the conus arteriosus of other vertebrates. This is a long conical organ, which forms the skeleton of the visceral arches in the Gnathostomata. Therefore, homologous in position, and this has led many to doubt their actual homology with the cartilaginous visceral arches. Taking into account, however, present knowledge of the development of the two sets of structures, it seems probable that a primitive archology exists and that the branchial basket of the lamprey represents merely a set of visceral arches modified in accordance with the peculiar breathing methods of the creature. In the Myxinoidea the branchial basket is greatly simplified.

**Venous System.**—The main venous channels are like those in other fishes, though their connexion with the heart becomes modified in the adult. The two posterior cardinals—with their anterior extensions forwards, the anterior cardinals—approach the median plane and undergo fusion in the region of their opening into the two ductus Cuvieri. The left ductus Cuvieri then atrophies so that all the blood from the cardinals reaches the heart by way of the originally right
ducous Cuvieri. It is this right ducous Cuvieri which forms the dorsal part of what is usually termed the sinus venosus. The inferior jugular veins which return the blood from the ventral side of the head also become replaced in the adult by a median unpaired vein which descends to the heart. The sinus venosus, which represents the hinder end of the original right inferior jugular. It is interesting to note that in Polypterus, one of the Cyclostomata, there is a somewhat similar asymmetrical condition of inferior jugulars.

Ostisation of Lamprey (6).—The lamprey chooses as spawning ground a part of the stream with fairly rapid current and where the bottom is composed of sand with scattered stones. By means of the suetaceous mollusk, stones are removed from the sand, which causes them to form a shallow excavation. The male and female frequently work together at the task of preparing the nest. When oviposition is about to take place, the male may be seen to suddenly attach himself to the female, and the female with the卵s becomes the check on to one of the stones at the upper margin of the nest. The urgenal opening of the male, with its specially prominent papilla, is approximated to that of the female, and with a peculiar quivering movement the two organs meet and the masses of sand stirred up by the movements of the tail. The eggs fertilized thus at the moment of exit are very sticky from their coating of albumen, and become weighted down by adherent grains of sand.

Development.—The development of the lamprey is of much morphological importance from the archaic nature of the creature and from the fact that the egg is comparatively small (about 1 mm. in diameter) and is sometimes enveloped by a soft case resembling the egg of yolk. It has been worked out so far only in the river lamprey (7). Segmentation is complete and unequal. If, as well as the process of gastrulation, agrees in its main features with the phenomenon in Amblystoma, the lamellated blastulas of the amphibians will represent the anal opening of the adult. The mesoderm arises in a manner closely comparable with that which occurs in Amblystoma, the chief difference being that the mesoderm segments are solid instead of hollow, and that the anterior end of this region is left free where the hind end becomes ectodermal pouches. The rudiment of the central nervous system has the form of a solid cell-ledge ingrowths of ectoderm along the mid-dorsal line, which secondarily becomes hollowed out—just as happens in teleostean fishes. The young lamprey retains for some time its embryonic development, perhaps for four years, in fact its whole life up to the time of sexual maturity, in a prolonged larval condition in which its structure shows important differences from that of the adult. This larval state, however, is never developed to a separate genus of Cyclostomes and was called Ammocoetes. The Ammocoetes lives in the mud and breathes and feeds by means of a current of water produced by ciliary action, which carries Flagellates and microscopic organisms in through the mouth opening. Correlated with this mode of feeding the buccal cavity is without the teeth so characteristic of the adult. A number of complicated branched sensory processes grow into and nearly occlude the kidney, forming a kind of highly developed gill through which the current passes. The water passes out by the gill openings, which in the young Ammocoetes open direct from pharynx to exterior. Certain arrangements of the pharyngeal wall of Ammocoetes show a remarkable agreement with the arrangement of the adult, and is found in all cyclostomes. The mouth, which in the adult is a complicated ductless gland, has in the young Ammocoetes the form of a longitudinal groove of the ventral wall of the pharynx. This groove is lined by columnar cells, some carrying cilia, others being glandular and secreting mucus. These cells are arranged in four longitudinal bands. The thyroid is, in fact, in this stage in a condition corresponding exactly with the endoderm of Amblystoma. The agreement extends to function, the secretion, forming sticky threads which hold the sand particles. Anteriorly a pair of pharyngeal bands pass dorsally, one on each side, to bind back suprabranchial bands which are continuous to the hinder end of the pharynx. Here again the resemblance to that of the adult is very close.

The Ammocoetes possesses a functional liver with bidentate, while in the adult river lamprey the alimentary canal is degenerate. It has no arch elements on its notchoid. Its eyes are sunk beneath the skin and are connected with the brain by a pair of ducts to the embryonic character (8). There is a rapid process of metamorphosis from the larval to the adult condition, the details of which are by no means sufficiently known. After the metamorphosis the new mouth throws back the arches which the adult pharynx apparently dies almost immediately. The development of the Myxinae is much less well known than that of the lampreys. As regards the common hagfish (Myxine glutinosa), we are indeed still in considerable ignorance with regard to the development. Despite of persistent efforts to obtain embryological material. It seems probable that during the breeding period the hagfishes retire into some particularly inaccessible habitat. Within the last few years, however, a great amount of material illustrating the developmental history of B delostoma (9) has been obtained off the Californian coast, and this when fully worked out will give us a good idea of the general lines of Myxine development. The egg is greatly different from that of the lamprey. It is—such as that of Myxine—large size, richly yolked, and is of a shortened-up sausage shape. It measures about 22 mm. by 8 mm. Surrounding the egg is a protective capsule of a yellow horn appearance. At one end a cap-like portion of this forms a detachable operculum, in the middle of which is a minute hole. In one or two cases of the capsule is prolonged into a group of stiff processes with anchor-like expansions at their tips. Segmentation is, as in other richly yolked eggs, incomplete, confined to the genital disk at the opercular pole. The central nervous system of Polypterus and Belonostomus is such as to leave the myotomes to form a median line of solid but not of a solid keel as is the case with the lamprey.

History of Time. —The softness of the skeletal tissues and the absence of scales in Cyclostomata provide little opportunity for the preservation of fossils, and no known fossils can be referred with certainty to the Cyclostomata. The Devonian Palaeoniscus gunni has been regarded as a Cyclostome by some authors; this relationship is at least doubtful. Other authors have placed it in the Osteostracans, the oldest known vertebrates, with this group.

CYCLOSTYLE (Gr. κύκλος, a circle, and στῦλος, a column), a term used in architecture. A structure composed of a circular range of columns without a core is cyclostyle; with a core the range would be peristyle. This is the species of edifice called by Vitruvius monopteral.

CYGNUS ("The Swan"), in astronomy, a constellation of the northern hemisphere, mentioned by Eudoxus (5th century B.C.) and Aratus (3rd century B.C.), and fabled by the Greeks as the swan in the form of which Zeus seduced Leda. Ptolomy catalogued 10 stars, Tycho Brahe 18, and Hevelius 47. In this constellation C. Cygni is a fine coloured double star, consisting of a yellow star, magnitude 3, and a blue star, magnitude 5. The fine double star, µ Cygni, separated by Sir William Herschel in 1779, has magnitudes 4 and 5; it has a companion, of magnitude 7½, which, however, does not form part of the system. A double star, δ1 Cygni, of magnitudes 5·3 and 5·9, was the first star whose distance was determined; its parallax is 0·39, and it is therefore the nearest star in the northern hemisphere with the exception of a Centauri. A regular variable, χ Cygni, has extreme magnitudes of 5 to 13·5, and its period is 406 days. Nova Cygni is a "new" star discovered by Johann Schmidt in 1766. There is also an extended nebula in the constellation.

CYLINDER (Gr. κύλινδρος, from κυλίνδω, to roll). A cylindrical surface, or briefly a cylinder, is the surface traced out by a line, named the generatrix, which moves parallel to itself and always passes through the circumference of a curve, named the directrix; the name cylinder is also given to the solid contained between such a surface and two parallel planes which intersect a generatrix. A "right cylinder" is the solid traced out by a rectangle which revolves about one of its sides, or the curved surface of this solid; the surface may also be defined as the locus of a line which passes through the circumference of a circle, and is always perpendicular to the plane of the circle. If the moving line be not perpendicular to the plane of the circle, but moves parallel to itself, and always passes through the circumference, it traces an "oblique cylinder." The "axis" of a circular cylinder is the line joining the centres of two circular sections; it is the line through the centre of the directrix parallel to the generators. The characteristic property of all cylindrical surfaces is that the tangent planes are parallel to the axis. They are "developable" surfaces, i.e., they can be applied to a plane surface without crinkling or tearing (see SURFACE).

The cross section of a cylinder is a circle, and this is termed a "principal section"; in the case of the solids this section is a rectangle; in the case of the surfaces, two parallel straight lines. A section of the right cylinder parallel to the base is obviously a circle; any other section, excepting those limited by two
generators, is an ellipse. This last proposition may be stated in
the form: — "The orthogonal projection of a circle is an ellipse."; and
it permits the ready deduction of many properties of the ellipse
from the circle. The section of an oblique cylinder by a plane
perpendicular to the principal section, and inclined to the axis
at the same angle as the base, is named the "subcontrary
section," and is always a circle; any other section is an ellipse.

The mensuration of the cylinder was worked out by Archi-
medes, who showed that the volume of any cylinder was equal
to the product of the area of the base into the height of the solid,
and that the area of the curved surface was equal to that of a
rectangle having its sides equal to the circumference of the base,
and to the height of the solid. If the base be a circle of radius
r, and the height h, the volume is \( \pi rh \) and the area of the curved
surface \( 2\pi rh \). Archimedes also deduced relations between the
sphere (q.v.) and cone (q.v.) and the circumscribing cylinder.

The name "cylindroid" has been given to two different
surfaces. Thus it is a cylinder having equal and parallel elliptical
bases; i.e., the surface traced out by an ellipse moving parallel
to itself so that every point passes along a straight line, or by a
line moving parallel to itself and always passing through the
circumference of the ellipse. Fixing the ellipse, the name was also given
by Arthur Cayley to the conoidal cubic surface which has for its
equation \( \frac{x^2}{m^2} + \frac{y^2}{n^2} + \frac{z^2}{p^2} = 2mx z \); every point on this surface lies on the
line given by the intersection of the planes \( y = \tan \theta \frac{s}{m} \sin \phi \), for by eliminating \( \theta \) we obtain the equation to the surface.

CYLLENE (mod. Ziria), a mountain in Greece, in the N.E.
of Arcadia (7789 ft.). It was especially sacred to Hermes, who
was born in a cave on the mountain, and had a temple and an
ancient statue on its summit. The name Cyllene belongs also
to an ancient town in Elis, and, owing to doubtful identifica-
tion with this, to a modern port at Glarentza, and also to some
mineral baths a little to the south of it.

CYMA (Gr. κύμα, wave), in architecture, a moulding of double
curvature, concave at one end, convex at the other. When the
concave part is uppermost, it is called a cyma recta; but if the
convex portion is at the top, it is called a cyma reversa. When
the crowning moulding of an entablature is of the cyma form,
it is called a "cymatium."

CYMBALS (Fr. cymbales; Ger. Becken; Ital. piatti or cinelii),
a modern instrument of percussion of indefinite musical pitch,
whereas the small ancient cup-shaped cymbals sounded a definite
note. Cymbals consist of two thin round plates of an alloy
containing 8 parts of copper to 2 of tin, each having a handle-
strap set in the little knob surmounting the centre of the plate.
The sound is obtained not by clashing them against each other,
but by rubbing their edges together by a sliding movement.
Sometimes a weird effect is obtained by suspending one of the
cymbals by the strap and letting a drummer execute a roll upon
it as it swings; or by holding a cymbal in the left hand and
striking it with the soft stick of the bass drum, which produces
a sound akin to that of the tam-tam. All gradations of piano
and forte can be obtained on the cymbals. The composer
indicates his intention of letting the cymbals vibrate by "Let
them vibrate," and the contrary effect by "Don’t let them
vibrate." To stop the vibrations the percussionist places the cymbals
against his head, and "stop" was the cymbal player’s signal. The
duration of the vibration is indicated by the value of the note placed
upon the staff; the name signifies nothing, since the pitch of the cymbals
is indefinite. The instrument is played from the same part of the
score as the bass drum, unless otherwise indicated by "senza
piatti, or piatti soli if the bass drum is to remain silent. Although
cymbals are not often required they form part of every orchestra;
their chief use is for marking the rhythm and for producing
wild, fantastic effects or adding military colour, and their
shriek notes hold their own against a full orchestra playing
fortissimo. Cymbals are specially suited for suggesting frenzy,
 fury or bacchanalian revels, as in the Venus music in Wagner’s
Tannhäuser and Grieg’s Peer Gynt suite. Damping gives
a suggestion of impending evil or tragedy. The timbre of
the ancient cymbals is entirely different, more like that of small
hand-bells or of the notes of the keyed harmonica. They are
not struck full against each other, but by one of their edges,
and the note given out by them is higher in proportion as they
are thicker and smaller. Berlioz in Romeo and Juliet scored
for two pairs of cymbals, modelled on some ancient Pompeian
instruments no larger than the hand (some are no larger than
a crown piece), and tuned to \( \frac{c}{d} \) and \( \frac{e}{f} \).

The origin of the cymbals must be referred to prehistoric times.
The ancient Egyptian cymbals closely resembled our own. The
British Museum possesses two pairs, 54 in. in diameter, one of
which was found in the coffin of the mummy of Ankh-shaped, a sacred
musician; they are shown in the same case as the mummy, and
have been reproduced by Carl Engel.\(^1\) Those used by the Assyrians
were both plate- and cup-shaped. The Greek cymbals were cup-
or bell-shaped, and are to be seen in the hands of fauns and satyrs
innumerable in sculptures and on painted vases. The word cymbal
is derived from κύμβα (Lat. cymba), a hollow vessel, and ςωδάς =
small cymbals. During the middle ages the word cymbal was applied
to the Glockenspiel, or reel of small bells, and later to the
dulcimer, perhaps on account of the clear bell-like tone produced
by the hammers striking the wood of the instrument. After the introduction
of invention of the keyed dulcimer or clavicord, and of the spinet,
the word clavicymbal was used in the Romance languages to denote
the varieties of spinet and harpsichord. Ancient cymbals are among
the mementoes of the medieval minstrel and his musicians in the
16th century illuminated MS. known as the Bible of Charles the Bald

CYNEGILS (d. 643), king of the West Saxons, succeeded his
uncle King Ceolwulf in 611. With his son Cwichelm (d. 636),
he defeated the advancing Britons at Bampton in Oxfordshire
in 614, and Cwichelm sought to arrest the growing power of
the Northumbrian king Eadwine by procuring his assassination;
the attempt, however, failed, and in 626 the West Saxons
were defeated in battle and forced to own Eadwine’s supremacy.
Cynegil’s next struggle was with Penda of Mercia, and here
again he was worsted, the battle being fought in 628 at Cire-
cester, and was probably compelled to surrender part of his
kingdom to Mercia. Cynegil’s was converted to Christianity
through the ministrations of Birinus, and was baptized in 634 at
Dorchester in Oxfordshire, where he founded a bishopric. He
was succeeded as king by his son Cenwulf.

CYNEWULF (d. 785), king of Wessex, succeeded to the throne
in 757 on the deposition of Egbert. He was constantly at
war with the Welsh. In 779 Offa of Mercia defeated him and
took Beningbrough. In 785 he was surprised and killed, with all
his thegns present, at Martin, Wilts (Merantune), by Cyne-
heard, brother of the deposed Egbert.

CYNEWULF, the only Old-English vernacular poet, known
by name, of whom any undisputed writings are extant. He is
the author of four poems preserved in two MSS., the Exeter
Book and the Vercelli Book, both of the early 11th century.
An epilogue to each poem contains the runic characters answering
to the letters c, y, a (ō), s, h, l, f. The runes are to be read as the
words (their runes) in their runes; these words enter into the
verse of the verse, and (except in one poem) are significant
in their context. The poems thus signed are the following:
(1) A meditation on The Ascension, which stands in the Exeter
Book between two similar poems on the Incarnation and the Last
Judgment. The three are commonly known as Cynewulf’s Christ,
but the runic signature attests only the second. (2) A
version of the legend of the martyr St Juliana, also in the
Exeter Book. (3) Elene, in the Vercelli Book, on the story of
the emperor Helena and the “Invention of the Cross.” (4) A
short poem on The Fates of the Apostles, in the same MS.
The page containing the signature to this poem was first discovered
by Professor A. S. Napier in 1888, so that the piece is not included
in earlier enumerations of the poet’s signed works.

In Juliana and Elene the name is spelt Cynewulf; in The
Ascension the form is Cynewulf. In The Fates of the Apostles
the page is defaced, but the spelling Cynewulf is almost certain.

\(^1\) The Music of the Most Ancient Nations, fig. 76, p. 227.
The absence of the E in The Ascension can hardly be due to a scribal omission, for the name of this letter (meaning “horse”) would not suit the context; this was perhaps the motive for the choice of the shorter form. The orthography (authenticated as the poet’s own by the nature of his device) has chronological significance. If the poems had been written before 740, the spelling would almost certainly have been Cynwulf. If it were safe to judge from the scanty extant evidence, we should conclude that the form Cynwulf came in about 800; and presumably the poet would not vary his accustomed signature until the new form had become common. In Elene Cynwulf speaks of himself as an old man; and the presence of the runic signature in the four works suggests that they are not far apart in date. They may therefore be referred provisionally to the beginning of the 9th century, any lower date being for linguistic and metrical reasons improbable.

The MSS. of the poems are in the West-Saxon dialect, with occasional peculiarities that indicate transcription from Northumbrian or Mercian. Professor E. Sievers’s argument for a Northumbrian original has considerable weight, for the Mercian theory no linguistic arguments have been adduced, but it has been advocated on grounds of historical probability which seem to be of little value.

Cynwulf’s unpretentious verse shows that he was a scholar, familiar with Latin and with religious literature, and that they measure skill and felicity in the use of traditional poetic language; but of the higher qualities of poetry they give little evidence. There are pleasing passages in Elene, but the clumsy and tasteless narration of the Latin original is faithfully reproduced, and the added descriptions of battles and voyages are strings of conventional phrases, with no real imagination. In The Ascension the genuine religious fervour imparts a higher tone to the poetry; the piece has real and not extraordinary merit. Of the other two poems no critic has much to say in praise.

If Cynwulf is to be allowed high poetic rank, it must be on the ground of his authorship of other works than those which he has signed. At one time or other nearly the whole body of extant Old English poetry (including Beowulf) has been conjecturally assigned to him. Some of the attributed works show many striking resemblances in style and diction to his authentic writings. But it is impossible to determine with certainty how far the similarities may be due to imitation or to the following of a common tradition.

Until recently, it was commonly thought that Cynwulf’s authorship of the Riddles (q.v.) in the Exeter Book was beyond dispute. The monodramatic lyric Wulf and Eadwacer, imagined to be the first of these Riddles, was in 1857 interpreted by Heinrich Leo as a charade on the name Cynwulf. This absurd fancy was for about thirty years generally accepted as a fact, but is now abandoned. Some of the Riddles have been shown by Professor E. Sievers to be older than Cynwulf’s time; that he may have written some of the rest remains a bare possibility.

The similarity of tone in the three poems known as the Christ affords some presumption of common authorship, which the counter arguments that have been urged seem insufficient to set aside. Both The Incarnation and The Last Judgment contain many passages of remarkable power and beauty. It is unlikely that the author regarded the three as forming one work. The Christ is followed in the MS. by two poems on Saint Guthlac, the second of which is generally, and with much probability, assigned to Cynwulf. The first Guthlac poem is almost universally believed to be by another hand. Cynwulf’s celebration of a midland saint is the strongest of the arguments that have been urged against his Northumbrian origin; but this consideration is insufficient to outweigh the probability derived from the linguistic evidence.

Cynwulf’s reputation can gain little by the attribution to him of Guthlac, which is far inferior even to Juliana. Very different would be the effect of the establishment of his much disputed claim to Andreas, a picturesque version of the legend of the Apostle Andrew. The poem abounds to an astonishing extent in “Cynwulfian” phrases, but it is contended that these are due to imitation. If the author of Andreas imitated Elene and Juliana, he bettered his model. The question whether Cynwulf may not have been the imitator has apparently never been discussed. The poem (so far agreeing with The Fates of the Apostles) copies the style of the old heroic poetry.

Cynwulf’s authorship has been asserted by some scholars for The Dream of the Rood, the noblest example of Old English religious poetry. But an extract from this poem is carved on the Ruthwell Cross; and, notwithstanding the arguments of Prof. A. S. Cook, the language of the inscription seems too early for Cynwulf’s date. The similarities between the Dream and Elene are therefore probably due to Cynwulf’s acquaintance with the older poem.

The only remaining attribution that deserves notice is that of the Phoenix. The author of this fine poem was, like Cynwulf, a scholar, and used many of his turns of expression, but he was a man of greater genius than is shown in Cynwulf’s signed compositions.

Professor M. Trautmann, following J. Grimm and F. Dietrich, would identify the poet with Cynwulf, bishop of Lindisfarne, who died in 783. This speculation conflicts with the chronology suggested in this article, and is destitute of evidence. Cynwulf was probably a Northumbrian churchman, but it is unlikely that there were not many Northumbrian scribes bearing this common name; and as the bishop is not recorded to have written anything, the identification is at best an unsupported possibility. Professor A. S. Cook has suggested that our Cynwulf may have been the “Cynulf,” priest of Dunwich, whose name is among those appended to a decree of the council of Clofesho in 803, and of whom nothing else is known. This conjecture suits the probable date of Cynwulf, but otherwise there is nothing in its favour.

For the older literature relating to Cynwulf, see R. Wülker, Grundriss der angelsächsischen Literatur (1885). References to the most important later discussions will be found in M. Trautmann, Cynwulf, der Bischof und Dichter (1898), and the introductions and notes to the editions of Cynwulf’s Christ, by I. Gollan (1892) and A. S. Cook (1900). For the arguments for Cynwulf’s authorship of Andreas, see F. Ramhorn, Andreas and Cynwulf (1885), (H. Br.)

Cynics, a small but influential school of ancient philosophers. Their name is variously derived from the building in Athens called Cynosarges, the earliest home of the school, and from the Greek word for a dog (κύων), in contemptuous allusion to the uncouth and aggressive manners adopted by the members of the school. Many of these explanations is correct: it is noticeable that the Cynics agreed in taking a dog as their common badge or symbol (see Diogenes). From a popular conception of the intellectual characteristics of the school comes the modern sense of “cynic,” implying a sneering disposition to disbelieve in the goodness of human motives and a contemptuous feeling of superiority.

As regards the members of the school, the separate articles on Antisthenes, Crates, Diogenes and Demetrius contain all biographical information. We are here concerned only to examine the general principles of the school in its internal and external relations as forming a definite philosophic unit. The importance of these principles lies not only in their intrinsic value as an ethical system, but also in the fact that they form the link between Socrates and the Stoics, between the essentially Greek philosophy of the 4th century B.C. and a system of thought which has exercised a profound and far-reaching influence on medieval and modern ethics. From the time of Socrates in unbroken succession up to the reign of Hadrian, the school was represented by men of strong individuality. The leading earlier Cynics were Antisthenes, Diogenes of Sinope, Crates of Thebes and Zeno; in the later Roman period, the chief names are Demetrius (the friend of Seneca), Censorinus and Democritus. All these men adhered steadfastly to the principles laid down by Antisthenes.

Antisthenes was a pupil of Socrates, from whom he imbibed the fundamental ethical precept that virtue, not pleasure, is the end of existence. He was, therefore, in the forefront of that intellectual revolution in the course of which speculation ceased
important as the precursors of Stoicism. The closeness of
the connection is illustrated by Juvenal's epigram that a cynic
differed from a stoic only by his cloak. Zeno was a pupil of
Crates, from whom he learned the moral worth of self-control
and indifference to sensual indulgence (see stoics).

Finally it is necessary to point out two flaws in the Cynic
philosophy. In the first place, the content of the word "knowledge"
is never properly developed. "Virtue is knowledge,"
knowledge of what? and how is that knowledge related to
the will? These questions were never properly answered by them.
Secondly they fell into the natural error of emphasizing the purely
animal side of the "nature," which was their ethical criterion.
Avoiding the artificial restraints of civilization, they were prone
to fall back into animalism pure and simple. Many of them
upheld the principle of community of wives (see Diogenes
Laertius vi. 11); some of them are said to have outraged
the dictates of public decency. It was left to the Stoics to separate
the wheat from the chaff, and to assign to the words "knowledge"
and "nature" a saner and more comprehensive meaning.

For relation of Cynicism to contemporary thought, compare
Cyrenaics, Megarian School. See also ASCETICISM.

CYNOPODIUM (Lat. cynopoïdion, Gr. κυνοποιών, from κύων,
genitive of κῦων, a dog, and ποίω, to make, that is, to,
for they were used to make wine); the name given by the
Greeks and Romans to the constellation of the Little Bear, Ursa
Minor, which in the northern sky is depicted as a dog, and
which appears in that constellation, and hence to something
which, like a "guiding-star," draws all attention to it, as, in
Milton's "cynopoïd of neighbouring eyes."

CYPERACEAE, in botany, a natural order of the monocytole-
donous group of seed-bearing plants. They are grass-like herbs,
sometimes annual, but more often persist by means of an under-
ground stem from which spring erect solitary or clustered,
generally three-sided aerial stems, with leaves in three rows.
The minute flowers are arranged in spikelets somewhat as in:
grasses, and these again in larger spike-like or panicle-like
spikelets. The flower has in rare cases a perianth of six scale-like
leaves arranged in two whorls, and thus conforming to the
common monocotyledonous type of flower. Generally the perianth
is represented by hairs, bristles or similar developments, often
indifferent in number; in the two largest genera, Cyperus (fig. 1)
and Carex (fig. 2), the flowers are naked. In a few cases two
whorls of stamens are present, with three members in each, but
generally only three are present; the pistil consists of three or two
carpels, united to form an ovary bearing a corresponding number
of styles and containing one or more ovules. The flowers which
are often unisexual are wind-pollinated. The fruit is one-seeded,
with a tough, leathery or hard wall. There are nearly 700 genera
containing about 3000 species and widely distributed throughout
the earth, chiefly as marsh-plants. In the arctic zone they form
10% of the flora; they will flourish in soils rich in humus which
are too acid to support grasses. The large genus Cyperus contains
about 400 species, chiefly in the warmer parts of the earth; C. Papyrus
is the Egyptian Papyrus. Carex,
the largest genus of the order, the sedges, is widely distributed in the temperate, alpine, and arctic regions of both hemispheres, and is represented by 60 species in Britain. Carex arenaria, the sea-bent, grows on sand-dunes and helps to bind the sand with its long cord-like underground stem which branches widely. Scirpus lacustris (fig. 3, 1) the true bulrush, occurs in lakes, ditches and marshes; it has a spongy, green, cylindrical stem, reaching nearly an inch in thickness and 1 to 8 ft. high, which is usually leafless with a terminal branched inflorescence. Eriophorum (fig. 3), cotton-grass, is represented in Britain by several species in boggy land; they are small tufted herbs with cottony heads due to the numerous hair-like bristles which take the place of the perianth and become much elongated in the fruiting stage.

CY-PRÈS (A.-Fr. for "so near"), in English law, a principle adopted by the court of chancery in dealing with trusts for charitable purposes. When the charitable purpose intended by a testator cannot be carried into effect, the court will apply the funds to some other purpose, as near the original as possible (whence the name). For instance, a testator having left a fund to be divided into four parts—one-fourth to be used for "the redemption of British slaves in Turkey and Barbary," and the other three-fourths for various local charities—it was found that there were no British slaves in Turkey or Barbary, and as to that part of the gift therefore the testator's purpose failed. Instead of allowing the portion of the fund devoted to this impossible purpose to lapse to the next of kin, the court devoted it to the purposes specified for the rest of the estate. This doctrine is only applied where "a general intention of charity is manifest" in the will, and not where one particular object only was present to the mind of the testator. Thus, a testator having left money to be applied in building a church in a particular parish, and that having been found to be impossible, the fund will not be applied cy-près, but will go to the next of kin.

In the United States, charitable trusts have become more frequent as the wealth of the country has progressed, and are regarded with increasing favour by the courts. The cy-près doctrine has been either expressly or virtually applied to uphold them in several of the states, and in some there has been legislation in the same direction. In others the doctrine has been repudiated, e.g. in Michigan, Tennessee, Indiana and Virginia. For many years the New York courts held that this doctrine was not in force there, but in 1893 the legislature repealed the provisions of the revised statutes on which these decisions rested and restored the ancient law. Statutes passed in Pennsylvania have established the doctrine there, and dissolved any doubt as to its being in force in that state.

CYPRESS (Cupressus), in botany, a genus of fifteen species belonging to the tribe Cupressineae, natural order Coniferae, represented by evergreen aromatic trees and shrubs indigenous to the south of Europe, western Asia, the Himalayas, China, Japan, north-western and north-eastern America, California and Mexico. The leaves of the cypresses are scale-like, overlapping and generally in four rows; the female catkins are roundish, and fewer than the male; the cones consist of from six to ten peltate woody scales, which end in a curved point, and open when the seeds are ripe; the seeds are numerous and winged. All the species exude resin, but no turpentine.

C. sempervirens, the common cypress, has been well known throughout the Mediterranean region since classic times; it may have been introduced from western Asia where it is found wild. It is a tapering, flame-shaped tree resembling the Lombardy poplar; its branches are thickly covered with small, imbricated, shining-green leaves; the male catkins are about 3 lines in length; the cones are between 1 and 1½ in. in diameter, sessile, and generally in pairs, and are made up of large angular scales, slightly convex exteriorly, and with a sharp point in the centre. In Britain the tree grows to a height of 40 ft., in its native soil to 70 or 90 ft. It thrives best on a dry, deep, sandy loam, on airy sheltered sites at no great elevation above the sea. It was introduced into Great Britain before the middle of the 16th century. In the climate of the south of England its rate of growth when young is between 1 and 1½ ft. a year. The seeds are sown in April, and come up in three or four weeks; the plants require protection from frost during their first winter.

The timber of the cypress is hard, close-grained, of a fine reddish hue, and very durable. Among the ancients it was in request for poles, rafts, joists, and for the construction of wine-presses, tables and musical instruments; and on that account was so valuable that a plantation of cypresses was considered a sufficient dowry for a daughter. Owing to its durability the wood was employed for mummy cases, and images of the gods;
CYPRIAN

a statue of Jupiter carved out of cypress is stated by Pliny to have existed 600 years without showing signs of decay. The cypress doors of the ancient St. Peter's at Rome, when removed by Eugenius IV., were about 1100 years old, but nevertheless in a state of perfect preservation. Laws were engraved on cypress by the ancients, and objects of value were preserved in receptacles made of it; thus Horace speaks of poems leví servanda cypresse.

The cypress, which grows no more when once cut down, was regarded as a symbol of the dead, and perhaps for that reason was sacred to Pluto; its branches were placed by the Greeks and Romans on the funeral pyres and in the houses of their departed friends. Its supposed ill-boding nature is alluded to in Shakespeare's Henry VI., where Suffolk describes for his enemies "their sweetest shade, a grove of cypress trees."

The cypress was the tree into which Cyparissus, a beautiful youth beloved by Apollo, was transformed, that he might grieve to all time (Ovid, Met. x. 3). In Turkish cemeteries the cypress—

"Dark tree, still sad when others' grief is fled,
The only constant mourner o'er the dead"—

is the most striking feature, the rule being to plant one for each interment. The tree grows straight, or nearly so, and has a gloomy and forbidding, but wonderfully stately aspect. With advancing age its foliage becomes of a dark, almost black hue. William Gilpin calls the cypress an architectural tree: "No Italian scene," he says, "is perfect without its tall spiral form, appearing as if it were not a part of the picturesquely disposed edifices which rise from the marshy ground against the distant landscape."

The cypress of Somma, in Lombardy, is believed to have been in existence in the time of Julius Caesar; it is about 121 ft. in height, and 23 ft. in circumference. Napoleon, in making the road over the Simplon, deviated from the straight line in order to leave it standing. The cypress, as the olive, is found everywhere in the dry hollows and high eastern slopes of Corfu, of the scenery of which it is characteristic. As an ornamental tree in Britain the cypress is useful to break the outline formed by round-headed low shrubs and trees. The berosh, or beroot, of the Hebrew Scriptures, translated "fir" in the Authorized Version, in 1 Kings v. 8 and vi. 15, 2 Chron. ii. 8 and many other passages, is supposed to signify the cypress.

The common or tall variety of C. sempervirens is known as C. fastigata; the other variety, C. horizontalis, which is little planted in England, is distinguished by its horizontally spreading branches, and its likeness to the cedar. The species C. torulosa of North India, so called from its twisted bark, attains an altitude of 150 ft.; its branches are erect or ascending, and grow so as to form a perfect circle. In the Kuril and Ladda country, the trees rise to the deities of the eleemosyne. It has been introduced into England, but does not thrive where the winter is severe. The wood, which in Indian temples is burnt as incense, is yellowish-red, close-grained, tough, hard, readily worked, durable, and equal in quality to that of the deodar. Another species, C. lusitanica or glauca, the "cedar of Goa," is a handsome tree, 50 ft. in height when full-grown, with spreading branches drooping at their extremities; it has been much planted in Portugal, especially in the neighbourhood of Cintra. Its origin is doubtful. It was well established in Portugal before the middle of the 17th century, and has since been cultivated generally in the south of Europe, but is nowhere believed to be indigenous. The name "cedar of Goa" is misleading, as no cypress is found wild anywhere near Goa. It was cultivated in England in the 17th century, and the name C. lusitanica was given by Philip Miller, the curator of the Chelsea Physick garden, in 1765, in reference to its supposed Portuguese origin. Experience has shown this cypress to be too tender for British climate generally, though good specimens are to be found in the milder climate of the south and west of England and in Ireland. C. Lawsoniana, the Portland cypress, native of south Oregon and north California, where it attains a height of 100 ft., was introduced into Scotland in 1834; it is much grown for ornamental purposes in Britain, a large number of varieties of garden origin being distinguished by differences in habit and by colour of foliage. Other Californian cypresses are C. macrocarpa, the Monterey cypress, which is 60 ft. high when mature, with a habit suggesting that of cedar of Lebanon, and C. Jentziana and C. Macaritnana, smaller trees generally from 20 to 30 ft. in height. C. funebris is a native of the north of China, where it is planted near pagodas. C. nootkatensis, the Nootka Sound cypress or Alaska cedar, was introduced into Britain in 1850. It is a hardy species, reaching a height of from 80 to 100 ft. Several varieties are distinguished by habit and colour of foliage. C. obtusa, a native of Japan, is a tall tree reaching 100 ft. in height, and widely planted by the Japanese for its timber, which is one of the best for interior construction. It is also cultivated by them as a decorative plant, in many forms, including dwarf forms not exceeding a foot in height.

The deciduous cypress, "swamp cypress" or "bald cypress," Taxodium distichum, is another member of the order Coniferae (tribe Taxodineae), a native of the southern United States and Mexico. It is a lofty tree reaching a height of 170 ft. or more, with a massive trunk 10 to 15 ft. or more in diameter, growing in or near water or on low-lying land which is subject to periodical flooding. The lower part of the trunk bears huge buttresses, each of which ends in a long branching fan-spreading root, from the branches of which spring the peculiar knees which rise above the level of the water. The knees are of a soft spongy texture and act as breathing organs, supplying the roots with air, which they would otherwise be unable to obtain when submerged. The stout horizontally spreading branches give a cedary appearance; the foliage is light and feathery; the leaves and the slender shoots which bear them fall in the autumn. The cones, about the size of a small walnut, bear spirally arranged imbricated scales which subdivide the three-angled winged seeds. The wood is light, soft, straight-grained and easily worked; it is very durable in contact with the soil, and is used for railway-ties, posts, fencing and for construction. The deciduous cypress was one of the first American trees introduced into England; it is described by John Parkinson in his Herbal of 1640. It thrives only near water or where the soil is permanently moist.

CYPRIAN, SAINT [Caeclius Cypri anus, called Thascitus] (c. 200–258), bishop of Carthage, one of the most illustrious in the early history of the church, and one of the most notable of its early martyrs, was born about the year 200, probably at Carthage. He was of patrician family, wealthy, highly educated, and for some time occupied as a teacher of rhetoric at Carthage. Of an enthusiastic temperament, accomplished in classical literature, he seems while a pagan to have courted discussion with those who would elsewhere have been afraid to dispute. When he entered ardenty into what was no doubt the great question of the time of Carthage as elsewhere. He sought to vanquish, but was himself vanquished by, the new religious force which was making such rapid inroads on the decaying paganism of the Roman empire. Caecilianus (or Caecilius), a presbyter of Carthage, is supposed to have been the instrument of his conversion, which seems to have taken place about 246.

Cyprian carried all his natural enthusiasm and brilliant powers into his new profession. He devoted his wealth to the relief of the poor and other piou uses; and so, according to his deacon Pontius, who wrote a diffuse and vague account of his "life and passion," "realized two benefits: the contempt of the world's ambition, and the observance of that mercy which God has preferred to sacrifice." The result of his charity and activity as a Christian convert was his unanimous call by the Christian people to be the head of the church in Carthage, at the end of 248 or beginning of 249. The time was one of fierce persecution directed against the Christians, and the bishop of Carthage became a prominent object of attack. During the persecution of Decius (250–251) Cyprian was exposed to imminent danger, and was compelled for a time to seek safety by his own flight. Gaius, the successor of Decius, the persecution was relaxed, and Cyprian returned to Carthage. Here he held several councils for the discussion of the affairs of the church, especially for grave questions as to the rebaptism of heretics, and the readmission into the church of the lapsi, or those who had fallen.
away through fear during the heat of the persecution. Cyprian, although inspired by lofty notions of the prerogatives of the church, and exposed to severity of opinion towards heretics, and especially heretical dissentients from the belief in the divine authorship of the episcopal order and the unity of Christendom, was leniently disposed towards those who had temporarily fallen from the faith. He set himself in opposition to Novatian, a presbyter of Rome, who advocated their permanent exclusion from the church; and it was his influence which guided the tolerant measures of the Carthaginian synods on the subject. While in this question he went hand in hand with Cornelius, bishop of Rome, his strict attitude in the matter of baptism by heretics brought him into serious conflict with the Roman bishop Stephen. It would almost have come to a rupture, since both parties held firmly to their standpoint, had not a new persecution arisen under the emperor Valerian, which threw all internal quarrels into the background in face of the common danger. Stephen became a martyr in August 257. Cyprian was at first banished to Curubis in Africa Proconsularis. But soon he was recalled, taken into custody, and finally condemned to death. He was beheaded on the 14th of September 258, the first African bishop to obtain the martyr's crown.

All Cyprian's literary works were written in connexion with his episcopal office; almost all his treatises and many of his letters have the character of pastoral epistles, and their form occasionally betrays the fact that they were intended as addresses. These writings bear the mark of a clear mind and a moderate and gentle spirit. Cyprian had none of that character which makes the reading of Tertullian, whom he himself called his master, so interesting and piquant, but he possessed other qualities which Tertullian lacked, especially the art of presenting his thoughts in simple, smooth and clear language, yet in a style which is not wanting in warmth and persuasive power. Like Tertullian, and often in imitation of him, Cyprian took certain apologetic, dogmatic and pastoral themes as subjects of his treatises. By far the best known of these is the treatise De catholicae ecclesiae unilate, called forth in 251 by the schism at Carthage, but particularly by the Novatian schism at Rome. This is perhaps the most clear-cut doctrine of the one Church founded upon the apostle Peter, whose "tangible bond is but one episcopal union, an apostleship universal yet only one—the authority of every bishop perfect in itself and independent, yet not forming with all the others a mere agglomeration of powers, but being a tenure upon a totality like that of a shareholder in some joint property."

Attention must also be called to the treatise Ad Donatum (De gratia dei), in which the new life after regeneration with its moral effects is set forth in a pure and clear light, as contrasted with the night of heathendom and its moral degradation, which were known to the author from personal experience. The numerous Letters of Cyprian are not only an important source for the history of church life and of ecclesiastical law, on account of their rich and manifold contents, but in large part they are important monuments of the literary activity of their author, since, not infrequently, they are in the form of treatises upon the topic in question. Of the eighty-two letters in the present collection, sixty-six were written by Cyprian. In the majority of cases the chronology of their composition, as far as the year is concerned, presents no difficulties; more precise assignments are mainly conjectural. In the editions of the works of Cyprian a number of treatises are printed which, certainly or probably, were not written by him, and have therefore usually been described as pseudo-Cyprian. Several of them, e.g. the treatise on dice (De aleatoribus), have attracted the attention of scholars, who are never weary of the attempt to determine the identity of the author, unfortunately hitherto without much success.

The best, though by no means faultless, edition of Cyprian's works is that of W. von Hartel in the Corpus scriptorum ecclesiasticorum (1 vols., 1868-1871). There is an English translation in the Library of the Anti-Nicene Fathers. The most complete monograph is that by Archbishop E. W. Benson, Cyprian, his Life, his Times, his Work (London, 1897). See also J. A. Faulkner, Cyprian the Churchman (Cincinnati and New York, 1906).

**CYPRINODONS—CYPRUS.** In spite of their name, the small fishes called Cyprinodonts are in no way related to the Cyprinids, or carp family, but are near allies of the pike, char, salmon, by a flat head with protractile mouth beset with cardiform, villiform, or compressed, bi- or tri-cuspid teeth, generally large scales, and the absence of a well-developed lateral line. About two hundred species are known, mostly inhabitants of the fresh and brackish waters of America; only about thirty are known from the old world (south Europe, south Asia, China and Japan, and Africa). Several forms occur in the Oligocene and Miocene beds of Europe. Many species are ovo-viviparous, and from their small size and lively behaviour they are much appreciated as aquarium fishes.

In many species the sexes are dissimilar, the female being larger and less brilliantly coloured, with smaller fins; the anal fin of the male may be modified into an intromittent organ by means of which internal fertilization takes place, the ova developing in a sort of uterus. In the remarkable genus *Anabeps*, from Central and South America, the strongly projecting eyes are divided by a horizontal band of the conjunctiva into an upper portion adapted for vision in the air, and a lower for vision in the water, and the pupil is also divided into two parts by a constriction.

The *Amblyopsidae*, which include the remarkable blind cave fishes of North America (Mammoth cave and others), are nearly related to the *Cyprinodontidae*, and like many of them ovo-viviparous. *Chologaster*, from the lowland streams and swamps of the south Atlantic states, has the eyes well developed and the body is coloured. *Amblyopsis* and *Typhlichthys*, which are evidently derived from *Chologaster*, or from forms closely related to it, but living in complete darkness, have the eyes rudimentary and more or less concealed under the skin, and the body is colourless.

**CYPRUS.** One of the largest islands in the Mediterranean, nominally in the denomination of Turkey, but under British administration, situated in the easternmost basin of that sea, at roughly equal distance from the coasts of Asia Minor to the north and of Syria to the east. The headland of Cape Kormakiti in Cyprus is distant 44 m from Cape Anamur in Asia Minor, and its north-east point, Cape St Andrea, is 60 m. from Latakia in Syria. It lies between 34° 33' and 35° 41' N., and between 32° 20' and 34° 35' E., so that it is situated in almost exactly the same latitude as Crete. Its greatest length is about 141 m., from Cape Drepano in the west to Cape St Andrea in the north-east, and its greatest breadth, from Cape Gata in the south to Cape Kormakiti in the north, reaches 60 m.; while it retains an average width of from 35 to 50 m. through the greater part of its extent, but narrows suddenly to less than 10 m. about 34° 5°, and from thence sends out a long narrow tongue of land towards the E.E.N. for a distance of 46 m., terminating in Cape St Andrea. The coast is generally low and rocky, and the island is the largest island in the Mediterranean after Sicily and Sardinia. In 1885 a trigonometrical survey and a map on the scale of 1 in. to 1 m. were made by Captain (afterwards Lord) Kitchener, R.E., who worked out the area of the island at 3584 sq. m., or a little more than the area of Norfolk and Suffolk.

**Mountains.**—Great part of the island is occupied by two mountain ranges, both of which have a general direction from west to east. Of these the most extensive, as well as the most lofty, is that which fills up almost the whole southern portion of the island, and is generally designated by modern geographers as Mount Olympus, though that name appears to have been applied by the ancients only to one particular peak. The highest summit is known at the present day as Mount Troodos, and attains an elevation of 6406 ft. It sends down subordinate ranges or spurs, of considerable altitude, on all sides, one of which extends to Cape Arnauti (the ancient Acamas) which forms the
or Chonia (4674), until it ends in the somewhat isolated peak called Santa Croce (Stavrovouni or Oro Stavro), the Hill of the Holy Cross (2260 ft.). This mountain, designated by Strabo Mount Olympus, is a conspicuous object from Larnaca, from which it is only 12 m. distant, and is well known from being frequented as a place of pilgrimage. The northern range of mountains begins at Cape Kormakiti (the ancient Crommony) and is continued thence in an unbroken ridge to the eastern extremity of the island, Cape St. Andrea, a distance of more than 100 m. It is not known by any collective name; its western part is called the Kyrenia mountains, while the remainder has the name of Carpus. It is inferior in elevation to the southern range, its highest summit (Buffavento) attaining only 3135 ft., while in the eastern portion the elevation rarely exceeds 2000 ft. But it is remarkable for its continuous and unbroken character—consisting throughout of a narrow but rugged and rocky ridge, descending abruptly to the south into the great plain of Lefkosa, and to the north to a narrow plain bordering the coast.

The Mesaoria.—Between the two mountain ranges lies a broad plain, extending across the island from the bay of Famagusta to that of Morphou on the west, a distance of nearly 60 m., with a breadth varying from 10 to 20 m. It is known by the name of the Mesaoria or Messaria, and is watered by a number of intermittent streams on the mountains on either hand. The chief streams are the Pedias and the Yalias, which follow roughly parallel courses eastward. The greater part of the plain is open and uncultivated, and presents nothing but barren downs; but corn is grown in considerable quantities in the northern portions of it, and there is no doubt that the whole is readily susceptible of cultivation. It is remarkable that Cyprus was celebrated in antiquity for its forests, which not only clothed the whole of its mountain ranges, but covered the entire central plain with a dense mass, so that it was with difficulty that the land could be cleared for cultivation. At the present day the whole plain of the Mesaoria is naturally bare and treeless, and it is only the loftiest and central summits of Mount Olympus that still retain their covering of pine woods. The disappearance of the forests (which has in a measure been artificially remedied) naturally affected the rivers, which are mostly mere torrents, dry in summer. Even the Pedias (ancient Pedieus) does not reach the sea in summer, and its stagnant waters form unhealthy marshes. In the marshy localities malarial fever occurs but is rarely (in modern times) of a severe type. The mean annual temperature in Cyprus is about 69°F. (mean maximum 78°, and minimum 57°). The mean annual rainfall is about 10 ins. October to March is the cool, wet season. Earthquakes are not uncommon.

Geology.—Cyprus lies in the continuation of the folded belt of the Anti-taurus. The northern coast range is formed by the oldest rocks in the island, consisting chiefly of limestones and marbles with occasional masses of igneous rock. These are supposed to be of Cretaceous age, but no fossils have been found in them. On both sides the range is flanked by sandstones and shales (the Kyrenian series), supposed to be of Upper Eocene age; and similar rocks occur around the southern mountain mass. The Oligocene consists of grey and white marls (known as the Idalian series), which are distributed all over the island and attain their greatest development on the south side of the Troodos. All these rocks have been folded, and take part in the formation of the mountains. The great igneous masses of the Troodos, &c., consisting of diabase, basal and serpentine, are of later date. The bed of the central plain is covered at various points by deposits of recent date and occur at intervals along the coast. The Pliocene is of marine origin, and rests unconformably upon all the older beds, including the Post-oligocene igneous rocks, thus proving that the final folding and the eruption of the basal of the Troodos occurred in the Miocene era. The caves of the Kyrenian range contain a Pleistocene mammalian fauna.

Population.—The population of Cyprus in 1901 was 237,022, an increase of 27,716 since 1891 and of 51,392 since 1881. The people are mainly Greeks and Turks. About 22% of the population are Moslems; nearly all the remainder are Christians of the Orthodox Greek Church. The Moslem religious courts, presided over by cadis, are strictly confined to jurisdiction in religious cases affecting the Mahomedan population. The island is divided into the six districts of Famagusta, Kyrenia, Larnaca, Limassol, Nicosia and Papho. The chief towns are Nicosia (pop. 14,752), the capital, in the north central part of the island, Limassol (8298) and Larnaca (7964) on the southeastern coast. The other capitals of districts are Famagusta on the east coast, Kyrenia on the north, and Kythma, capital of Papho, on the south-west. Kyrenia, a small port, has a castle built about the beginning of the 13th century, and notable, through the troubled history of the island, as never having been captured.

Agriculture, &c.—The most important species of the few trees that remain in the island are the Aleppo pine, the Pinus larico, cypress, cedar, carob, olive and Quercus alnifolia. Recent additions are the eucalyptus, casurina, Pinus pinea and ailanthus. Some protection has been afforded to existing plantations, and some attempt made to extend their area; but the progress in both directions is slow. Agriculture is the chief industry in the island, in spite of various disabilities. The soil is extremely fertile, and, with a fair rainfall, say 13 in., between November and April, yields magnificent crops, but the improvements in agriculture are scarcely satisfactory. The methods and appliances used are extremely primitive, and invertebrate prejudice debar the average peasant from the use of new implements, fresh seed, or manure; he generally cares nothing for the rotation of crops, or for the cleanliness of his land. Modern improvements and the use of imported machinery have, however, been adopted by some. A director of agriculture was appointed in 1866, and seeders are issued pointing out improvements within the means of the villagers, and how to deal with plant diseases and insect pests. The products of the soil include grain, fruit, including carob, olive, mulberry, cotton, vegetables and oil seeds. Vineyards occupy a considerable area, and the native wines are pure and strong, but not always palatable. The native practice of conveying wine in tanned skins was deleterious to its flavour, and is now for the most part abolished. A company has exploited and improved the industry. Large sums have been expended on the destruction of locusts; they are now practically harmless, but live locusts are diligently collected every year, a reward being paid by the government for their destruction. Under the superintendence of an officer lent by the government of Madras, two great works of irrigation, from the lack of which agriculture had seriously suffered, were undertaken in 1858 and 1890. The smaller includes a reservoir at Syncrapali (Famagusta), with a catchment of 27 sq. m. and a capacity of 70,000,000 cub. ft. It reclaimed 360 acres, and was estimated to irrigate 4320. The larger scheme includes three large reservoirs in the Mesaoria to hold up and temporarily store the flood waters of the Pedias and Yalias rivers. The estimate premised a cost of £50,000, the
irrigation of 42,000 acres, and the reclamation of 10,000. These works were completed respectively in 1899 and 1901.

The rearing of live stock is of no little importance. A committee exists "for the improvement of the breeds of Cyprus stock"; stallions of Arab blood have been imported, and prizes are offered for the best donkeys. Cattle, sheep, mules and donkeys are sent in large numbers to Egypt. Cyprus mules have found favour in war in the Crimea, India, Uganda, Eritrea and Egypt. The sea fisheries are not important, with the exception of the sponge fishery, which is under the protection of the administration. The manufactures of the island are insignificant.

Minerals.—Next to its forests, which long supplied the Greek monarchs of Egypt with timber for their fleets, Cyprus was celebrated among the ancients for its mineral wealth, especially for its mines of copper, which were worked from a very early period, and continued to enjoy such reputation among both Greeks and Romans that the modern name for the metal is derived from the term of Aes Cyprium or Cuprium by which it was known to the latter. According to Strabo the most valuable mines were worked at a place called Tamasus, in the centre of the island, on the northern slopes of Mount Olympus, but their exact site has not been identified. An attempt to work copper towards the close of the 19th century was a failure, but some prospecting was subsequently carried on. Besides copper, according to Strabo, the island produced considerable quantities of silver; and Pliny records it as producing various kinds of precious stones, among which he mentions diamonds and emeralds, but these were doubtless nothing more than rock crystal and beryl. Salt, which was in ancient times one of the productions for which the island was noted, is still made in large quantities, and there are extensive salt works in the neighbourhood of Larnaca and Limasol, where there are practically inexhaustible salt lakes. Rock crystal and asbestos are still found in the district of Paphos. Gypsum is exported unburnt from the Carpas, and as plaster of Paris from Limasol and Larnaca. Statuary marble has been found on the slopes of Buffavento in the northern range. Excellent building stone exists throughout the island.

Commerce.—A disability against the trade of Cyprus has been the want of natural harbours, the ports possessing only open roadsteads; though early in the 20th century the construction of a satisfactory commercial harbour was undertaken at Famagusta, and there is a small harbour at Kyrenia. Trade is carried on principally from the ports already indicated among the chief towns. The various agricultural products, cattle and mules, cheese, wines and spirits, silk cocoons and gypsum make up the bulk of the exports. Barley and wheat, carobs and raisins may be specially indicated among the agricultural exports. The annual value of exports and of imports (which are of a general character) may be set down as about £300,000 each. Good roads are maintained connecting the more important towns, and when the harbour at Famagusta was undertaken the construction of a railway from that port to Nicosia was also put in hand. The Eastern Telegraph Co. maintains a cable from Alexandria to Ismir, which goes on a great part of the line on the island. The Imperial Ottoman Telegraph Co. has also some lines. The British sovereign is the current gold coin, the unit of the bronze and silver coinage being the piaster (½ penny). Turkish weights and measures are used. The obe, equalling 2·8 lb avoirdupois, and the donum, about ½ of an acre, are the chief units.

Constitution and Government.—Under a convention signed at Constantinople on the 4th of June 1878, Great Britain engaged to join the sultan of Turkey in defending his Asiatic possessions (in certain contingencies) against Russia, and the sultan, "in order to enable England to make necessary provision for executing her engagement," consented to assign the island of Cyprus to be occupied and administered by England. The British flag was hoisted on the 12th of June, and the conditions of the occupation were explained in an annex to the convention, dated the 1st of July. An order in council of the 14th of September, modified so far as related to legislation by another of the 30th of November, regulated the government of the island. The administration was placed in the hands of a high commissioner with the usual powers of a colonial governor. Executive and legislative councils were established; and in each of the six districts into which, for administrative and legal purposes, the island was divided, a commissioner was appointed to represent the government. The executive council consists of the high commissioner, the chief secretary, the king's advocate, the senior officer in charge of the troops, and the receiver-general, with, as "additional" members, two Christians and one Mussulman. The legislative council consists of six non-elected members, being office-holders, and twelve elected members, three being chosen by the Moslems and nine by the non-Moslem inhabitants. British subjects and foreigners, who have resided five years in Cyprus, can exercise the franchise as well as Ottoman subjects. The qualification otherwise is the payment of any of the taxes classed as Vergi Taxes (see below). The courts in existence at the time of the occupation were superseded by the following, constituted by an order in council dated the 30th of November 1882:—(1) a supreme court of civil appeal; (2) six assize courts; (3) six district courts; (4) six magistrates' courts; and (5) village courts. Actions are divided, according to the nationality of the defendant, into "Ottoman" and "Foreign"; in the latter, the president of the court alone exercises jurisdiction as a rule, so also in criminal cases against foreigners. The law administered is that contained in the Ottoman codes, modified by ordinances passed by the legislative council.

Finance.—The principal sources of revenue are:—

1 Vergi taxes, or taxes on house and land property, and trade profits and incomes (not including salaries); (2) military exemption tax, payable by Moslems and Christians alike, but not by foreigners, and in some cases on men 18 and over; (3) 10% poll tax, and in some cases on men 18 and over; (4) sheet, goat, and hog tax; (5) an excise on wines, spirits and tobacco; (6) import duties; (7) stamps, court fees, royalties, licenses, &c.; (8) salt monopoly. Foreigners are liable to all the above taxes except the military exemption tax. The annual sum of £22,800, payable to Turkey as the average excess (according to the years 1873-1878) of revenue over expenditure, but really appropriated to the interest on the British guaranteed loan of 1855, is a heavy burden. But if not lightened, tax payers at least benefit by the concession to foreign trade.

Instruction.—A general system of grants in aid of elementary schools was established in 1882. There are some 300 connected with the Greek Orthodox Church, and 160 elementary Moslem schools. There are, in addition to a government medical department and 30 other schools a Moslem high school (maintained entirely by government), a training college at Nicosia for teachers in the Orthodox Church schools, Greek high schools at Larnaca and Limassol, an English school for boys and a girls' school in Nicosia. By law of 1895 separate boards of education for Moslem and Greek Christian schools were established, and in each district there are separate committees, presided over by the commissioner. An institution of special notice is the home and farm for lepers near Nicosia, accommodating over a hundred inmates.

History and Archaeology down to the Roman Occupation

The Stone Age has left but few traces in Cyprus; no sites have been found and even single implements are very rare. The "megalithic" monuments of Agia Phaneromeni1 and Halâ Sûltân Tekê near Larnaca may perhaps be early, like the Palestinian cromlechs; but the vaulted chamber of Agia Katina near Enkomi seems to be Mycenaean or later; and the bull's-eye rock-cut and monoliths perhaps belong to the period of prehistoric date.

The Bronze Age, on the other hand, is of peculiar importance in an area which, like Cyprus, was one of the chief early sources of copper. Its remains have been carefully studied both on

1 M. Ohnelasch-Richter, Arch. Zeitung (1881), p. 311, pl. xxi
The principal publications respecting this and all other phases of culture mentioned in this section are collected in Myres and Ohnelasch-Richter, Cyprus Museum Catalogue (Oxford, 1899), pp. 1-35.
settlement sites at Leondári Vounó and Kalopáda, and in tombs in more than thirty places, notably at Agía Paraskeví, Psennmatísmeno, Alámbrica, Episkopía and Enkomi. Throughout this period, which began probably before 3000 b.c. and ended about 1000 b.c., Cyprus evidently maintained a large population, and an art and culture distinct from those of Egypt, Syria and Cilicia. The Cyproite temper, however, lacks originality; at all periods it has accepted foreign innovations slowly, and discarded them even more reluctantly. The island owes its importance, therefore, mainly to its copious supply of a few raw materials, notably copper and timber. Objects of Cyproite manufacture are found but rarely on sites abroad; in the later Bronze Age, however, they occur in Egypt and South Palestine, and as far afield as Thera (Santorini), Athens and Troy (Hissarlik).

The Bronze Age culture of Cyprus falls into three main stages. In the first, the implements are rather of copper than of bronze, tin being absent or in small quantities (2 to 3%); the types are common to Syria and Asia Minor as far as the Hellaspolis, and resemble also the earliest forms in the Aegean and in central Europe; the pottery is all hand-made, with a red burnished surface, gourd-like and often fantastic forms, and simple geometrical patterns incised; zoomorphic art is very rare, and imported objects are unknown. In the second stage, implements of true bronze (5 to 10% tin) become common; painted pottery of buff clay with dull black geometrical patterns appears along the coast, and foreign imports occur, such as Egyptian blue-glazed beads (XIIth-XIIIth Dynasty, 2500-2000 B.C.) and cylindrical Asiatic seals (one of Sargón I., 2000 B.C.).

In the third stage, Aegean colonists introduced the Mycenaean (late Minoan) culture and industries; with new types of weapons, wheel-made pottery, and a naturalistic art which rapidly becomes conventional; gold and ivory are abundant, and glass and enamels are known. Extended intercourse with Syria, Palestine and Egypt brought other types of pottery, jewelry, &c. (especially scarabs of XVIIIth and XIXth Dynasties, 1600-1200 B.C.), which were freely copied on the spot. There is, however, nothing in this period which can be ascribed to specifically "Phoenician" influence; the only traces of writing are in a variety of the Aegean script. The magnificent tombs from Enkomi and Episkopía illustrate the wealth and advancement of Cyprus at this time.

It is in this third stage that Cyprus first appears in history, under the name *Aií*, as a conquest of Tethmois (Thotmes) III. of Egypt (XVIIth Dynasty, c. 1500 B.C.), yielding tribute of chariots, horses, copper, blue-stone and other products. It was still in Egyptian hands under Sekenenre (XVIIIth Dynasty), and under Rameses III. (1186-1156 B.C.), and town names seems to include among others the names of Salamis, Citium, Soli, Ialédis, Cerynía (Kyrenia), and Curium. Another Egyptian dependency, Alásia, has by some been identified with Cyprus or a part of it (but may perhaps be in North Syria). It sent copper, oil, horses and cattle, ivory and timber; under Amenophis (Amenhotep) III. it exported timber and imported silver; it included a town Siktá, traded with Byblos in North Syria, and was exposed to piratical raids of Lykki (? Lycians).

The decline of Egypt under the XXth Dynasty, and the contemporary fall of the Aegean sea-power, left Cyprus isolated and defenseless, and the Early Iron Age which succeeds is a period of obscurity and relapse. Iron, which occurs rarely, and almost exclusively for ornaments, in a few tombs at Enkomi, suddenly superseded bronze for tools and weapons, and its introduction was accompanied, as in the Aegean, by economic, and probably by political changes, which broke up the high civilization of the Mycenaean colonies, and reduced them to poverty, isolation and comparative barbarism. It is significant that the first iron swords in Cyprus are of a type characteristic of the islands bordering the Adriatic. Gold and even silver become rare; foreign imports almost cease; engraved cylinders and scarabs are replaced by conical and pyramidal seals like those of Asia Minor, and dress-pins by brooches (*fibulae*) like those of south-eastern Europe. Representative art languishes, except a few childish terra-cottas; decorative art becomes once more purely geometrical, but shows only slight affinity with the contemporary geometrical art of the Aegean.

Lingerings thus in Cyprus (as also in some islands of the Aegean) Mycenaean traditions came into contact with new oriental influences from the Syrian coast; and these were felt in Cyprus somewhat earlier than in the West. But there is at present no clear proof of Phoenician or other Semitic activity in Cyprus until the last years of the 8th century.

No reference to Cyprus has been found in Babylonian or Assyrian records before the reign of Sargón II. (end of 8th century B.C.), and the occasional discovery of Mesopotamian cylinders of early date in Cyprus is no proof of direct intercourse.6 Isaiah (xxiii. 1, 12), writing about this time, describes Kithium (a name derived from Citium, q.v.) as a port of call for merchantmen homeward bound for Tyre, and as a shelter for Tyrian refugees; but the Hellish geographers of this and the next century classify Kithium, together with other coast-lands and islands, under the heading *Iasos*, "Ionian" (q.v.), and consequently reckoned it as predominantly Greek.

Sargon's campaigns in north Syria, Cilicia and south-east Asia Minor (721-711) provoked first attacks, then an embassy and submission in 709, from seven kings of Yatnana (the Assyrian name for Cyprus); and an inscription of Sargon himself, found at Citium, proves an Assyrian protectorate, and records tribute of gold, silver and various timbers. These kings probably represent that "sea-power of Cyprus" which precedes that of Phoenicia in the Greek "List of Thalassocracies" preserved by Eusebius. Under Sennacherib's rule, Yatnana figures (as in Isaiah) as the refuge of a disloyal Sidonian in 702; but in 665 ten kings of Cyproite cities joined Assar-bani-pal's expedition to Egypt; most of them bear recognizable Greek names, e.g. Pylagoras of Cythroy, Eteandros of Paphos, Onasagoras of Ledra. They are gazetted with twelve other "kings of the Hatti" (S.E. Asia Minor). Citium, the principal Phoenician state, does not appear by name; but is usually recognized in the list under its Phoenician title *Karti-hadatu*, "city-town...". It is also mentioned, before the middle of the 7th century, Cyprus reappears in history divided among at least ten cities, of which some are certainly Greek, and one at least certainly Phoenician: with this, Greek tradition agrees.7 The Greek colonists traced their descent, at Curium, from Argos; at Lapathus, from Laconia; at Paphos, from Arcadia; at Salamis, from the Attic island of that name; and at Soli, also from Attica. The settlements at Paphos and Salamis, and probably at Curium, were believed to date from the period of the Trojan War, i.e. from the 13th century, and the latter part of the Mycenaean age; the name of Teucer, the legendary founder of Salamis, probably is a reminiscence of the piratical Tikkara who harried the Egyptian coast under Rameses III. (c. 1200 B.C.), and the discovery of late Mycenaean settlements on these sites, and also at Lapathus, suggests that these legends rest upon history. The Greek dialect of Cyprus points in the same direction; it shows marked resemblances with that of Arcadia, and forms with it a "south Achaeán" or "south Aeolic" group, related to the "northern Aeolic" of Thessaly and other parts of north Greece.8 Further

evidence of continuity comes from the peculiar Cyproite script, a syllabary related to the linear scripts of Crete and the south Aegean, and traceable in Cyprus to the Mycenaean age. It remained in regular use until the 4th century; before that time the Greek alphabet occurs in Cyprus only in a few inscriptions erected for visitors. In Citium and Idalium, on the other hand, a Phoenician dialect and alphabet were in use from the time of Sargon onward. Sargon's inscription at Citium is cuneiform.

The culture and art of Cyprus in this Graeco-Phoenician period are well represented by remains from Citium, Idalium, Tamassus, Amathus and Curium; the earlier phases are best represented round Laphas, Soli, Paphos and Citium; the later Hellenization, at Amathus and Marion-Arsinoë. Three distinct foreign influences may be distinguished: they originate in Egypt, in Assyria, and in the Aegean. The first two predominate earlier, and gradually recede before the last-named. Their effects are best seen in sculpture and in metal work, though it remains doubtful whether the best examples of the latter were made in Cyprus or on the mainland. Among a great series of engraved vases some, round mostly in Cyprus, but also as far off as Nineveh, Olympia, Caere and Praeneste, some examples show almost unmixed imitation of Egyptian scenes and devices; in others, Assyrian types are introduced among the Egyptian in senseless confusion; in others, both traditions are merged in a mixed art, which betrays a return to naturalism and a new sense of style, like that of the Idaean bronzes in Crete. From its intermediate position between the art of Phoenicia and its western colonies (so far as this is known) and the earliest Hellenic art in the Aegean, this style has been called Graeco-Phoenician. The same sequence of phases is represented in sculpture by the votive statues from the sanctuaries of Aphrodite at Dali and of Apollo at Vouni and Prangissa; and by examples from other sites in the Cesnola collection; in painting by a rare class of naively polychormic vases; and in both by the elaborately coloured terra-cotta figures from the "Tomba" site at Salamis. Gem-engraving and jewelry follow similar lines; pottery-painting for the most part remains geometrical throughout, with crude survivals of Mycenaean curvilinear forms. Those Aegean influences, however, which had been predominant in the later Bronze Age, and had never wholly ceased, revived, as Hellenism matured and spread, and slowly repelled the mixed Phoenician orientation. Imported vases from the Aegean, of the "Dipylon," "proto-Corinthian" and "Rhodian" fabrics, occur rarely, and were imitated by the native potters; and early in the 6th century appears the specific influence of Ionia, and still more of Naucratis in the Egyptian delta. For the failure of Assyria in Egypt in 668-664, and the revival of Egypt as a phil-Hellene state under the XXVIth Dynasty, admitted strong Graeco-Egyptian influences in industry and art, and led about 560 B.C. to the political conquest of Cyprus by Amasis (Ahmosi II.); once again Cyriote timber maintained a foreign sea-power in the Levan.

The annexation of Egypt by Cambyses of Persia in 525 B.C. was preceded by the voluntary surrender of Cyprus, which formed part of Darius's "fifth satrapy." The Greek cities, fasting still under Persia, and fortified by Onesicritus of Salamis, joined the Ionian revolt in 500 B.C.; but the Phoenician states, Citium and Amathus, remained loyal to Persia; the rising was soon put down; in 482 Cyprus furnished no less than 150 ships to the fleet of Xerxes; and in spite of the repeated attempts of the Delian League to "liberate" the island, it remained subject to Persia during the 5th century. The occasion of the siege of Idalium by Persians (which is commemorated in an important Cyriote inscription) is unknown. Throughout this period, however, Athens and other Greek states maintained a brisk trade in copper, sending vases and other manufactures in return, and bringing Cyprus at last into full contact with Hellenism. But the Greek cities retained monopolic government throughout, and both the domestic art and the principal religious cults remained almost unaltered. The coins of the Greek dynasts and autonomous towns are struck on a variable standard with a stater of 170 to 180 grs. The principal Greek cities were now Salamis, Curium, Paphos, Marion, Soli, Kyrenia and Cyprus; the Phoenician towns, Citium and Amathus on the south coast between Salamis and Curium and Tamassus and Idalium in the interior; but the last named was little more than a sanctuary town, like Paphos. At the end of the 5th century a fresh Salaminian League was formed by Evagoras (q.v.), who became king in 410, aided the Athenian Conon after the fall of Athens in 404, and revolted openly from Persia in 386, after the peace of Antalcidas. Athens again sent help, but as before the Phoenician states supported Persia; the Greeks were divided by feuds, and in 380 the attempt failed; Evagoras was assassinated in 374, and his son Nicocles died soon after. After the victory of Alexander the Great at Issus in 333 B.C. all the states of Cyprus welcomed him, and sent timber and ships for his siege of Tyre in 332.

After Alexander's death in 323 B.C. Cyprus, coveted still for its copper and timber, passed, after several rapid changes, to Ptolemy I., king of Egypt. Then in 306 B.C. Demetrius Poliorcetes of Macedon overran the whole island, besieged Salamis, and after a long siege defeated there the Egyptian fleet. Ptolemy, however, recovered it in 295 B.C. Under Ptolemaic rule Cyprus has little history. Usually it was governed by a viceroy of the royal line, but it gained a brief independence under Ptolemy Lathyrus (107-89 B.C.), and under a brother of Ptolemy Auletes in 58 B.C. The great sanctuaries of Paphos and Idalium, and the public buildings of Salamis, which were wholly remodelled in this period, have produced but few works of art; the sculpture from local shrines at Vouni and Vitsada, and the frescoed tombs from Amathus, show how incapable the Cypriotes still were of utilizing Hellenistic models; a rare and beautiful class of terra-cottas like those of Myrina may be of Cyriote fabric, but their style is wholly of the Aegean. It is in this period that we first hear of Jewish settlements, which later become very populous.

In 58 B.C. Rome, which had made large unsecured loans to Ptolemy Auletes, sent M. Porcius Cato to annex the island, nominally because its king had connived at piracy, really because its revenues and the treasures of tripod were coveted to finance the law of P. Clodius. Under Rome Cyprus was at first annexed to the province of Cilicia; after Actium (31 B.C.) it became a separate province, which remained in the hands of Augustus and was governed by a legatus Caesaris pro praetore as long as danger was feared from the East. No monuments

remain of this period. In 22 B.C., however, it was transferred to the senate, so that Sergius Paulus, who was governor in A.D. 46, is rightly called "proconsul." Of Paulus no coins are known, but an inscription exists. Other proconsuls are Julius Cordus and L. Annius Bassus who succeeded him in A.D. 52. The copper mines, which were of great importance, were farmed at one time by Herod the Great. The persecution of Christians on the mainland after the death of Stephen, about 100 A.D., is likewise known to us. In 117 the Jews of Cyprus, with those of Egypt and Cyrene, revolted, massacred 240,000 persons, and destroyed a large part of Salamis. Hadrian, afterwards emperor, suppressed them, and expelled all Jews from Cyprus.

For the culture of the Roman period there is abundant evidence from Salamis and Paphos, and from tombs everywhere, for the glass vessels which almost wholly supersede pottery are much sought for (quite accidental) iridescence; not much else is known, and little attention has been paid to the sequence of style.

The Christian church of Cyprus was divided into thirteen bishoprics. It was made autonomous in the 5th century, in recognition of the supposed discovery of the original of St. Matthew's Gospel in a "tomb of Barnabas," which is still shown at Salamis. The patriarch has therefore the title μακάριος καὶ αρχιεπίσκοπος των Κύπρων, and the right to sign his name in red ink. A council of Cyprus, summoned by Theophilus of Alexandria in A.D. 401, prohibited the reading of the works of Origen (see Cypriot Church). Of the Byzantine period little remains but the ruins of the castles of St. Hilarion, Buffavento and Kantara; and a magnificent series of gold ornaments and silver plate, found near Kyrenia in 1893 and 1897 respectively. Christian tombs usually contain nothing of value.

The Frankish period is represented by the "Crusaders' Tower" at Kolossi, and the church of St. Nicholas at Nicosia; and, later, by masterpieces of a French Gothic style, such as the church of St. Sophia, and other churches at Nicosia; the cathedral (mosque) and others at Famagusta (q.v.), and the monastery at Bella Pais; as well as by domestic architecture at Nicosia; and by forts at Kyrenia, Limasol and elsewhere.

The Turks and British have added little, and destroyed much, converting churches into mosques and grain-stores, and quarrying walls and buildings at Famagusta.

History of Excavation.—Practically all the archaeological discoveries above detailed have been made since 1877. A few chance finds of vases, inscriptions and coins; of a hoard of silver bowls at Dali (anc. Idalion) in 1851; and of a bronze tablet with Phoenician and Cypriote bilingual inscriptions, at Dali, and about the same time, had raised questions of great importance as to the art and the language of the ancient inhabitants. T. B. Sandwith, British consul 1865-1869, had laid the foundations of a sound knowledge of Cypriote pottery; his successor R. H. Lang (1870-1872) had excavated a sanctuary of Apollo at Dali; and at the time of the publication of the third part of the British Museum's Cypriote Art, General Louis P. de Cesnola (q.v.), American consul, was already exploring ancient sites, and opening tombs, in all parts of the island, though his results were not published till 1877. But though his vast collection, now in the Metropolitan Museum of New York, remains the largest series of Cypriote antiquities in the world, the accounts which have been given of its origin are so inadequate, and have provoked so much controversy, that its scientific value is small, and a large part of subsequent excavation has necessarily been directed to solving the problems suggested by its practically isolated specimens. From 1876 to 1878 Major Alexander P. di Cesnola continued his brother's work, but the large collection which he exhibited in London in 1880 was dispersed soon afterwards.

On the British occupation of Cyprus in 1878, the Ottoman law of 1874 in regard to antiquities was retained in force. Excavation is permitted under government supervision, and the finds are apportioned in thirds, between the excavator, the landowner (who is usually bought out by the former), and the government. The government thirds lie neglected in a "Cyprus Museum" maintained at Nicosia by voluntary subscription. There is no staff, and no effective supervision of ancient sites or monuments. A catalogue of the collections was published by the Oxford University Press in 1890.

Since 1878 more than twenty distinct excavations have been made in Cyprus, of which the following are the most important. In 1879 the British government used the acropolis of Citium (Larnaca) to fill up the ancient harbour; and from the destruction a few Phoenician inscriptions and a proto-Ionic capital were saved. In 1882 tombs were opened by G. Hake at Salamis and Curium for the South Kensington Museum, but no scientific record was made. In 1883 the Cyprus Museum was founded by private enterprise, and on its behalf Max Ohnefalsch-Richter, who had already made trial diggings for Sir Charles Newton and the British Museum, excavated sanctuaries at Voni and Kythrea (Chytri), and opened tombs on some other sites.

In 1885 Dr F. Dümmler opened tombs at Dali, Alambra and elsewhere, and laid the foundations of knowledge of the Bronze Age and Early Iron Age; and Richter, on behalf of officials and private individuals, excavated parts of Frangissa (Tamasus), Episkopi and Dali.

In the same year, 1885, and in 1886, a syndicate opened many tombs at Pili-tis-Khrysochou (Marium, Arsinoe), and sold the contents to a buyer in Paris. From Richter's notes of this excavation, Dr P. Herrmann compiled the first scientific account of Graeco-Phoenician and Hellenistic Cyprus. In 1886 also M. le vicomte E. de Castillon de St Victor opened rich Graeco-Phoenician tombs at Episkopi, the contents of which are in the Louvre.

The successes of 1885-1886 led to the foundation of the Cyprus Exploration Fund, on behalf of which (1) in 1888 the sanctuary of Aphrodite at Paphos (Kouklia) was excavated by Messrs E. Gardner, M. R. James, D. G. Hogarth and R. Elsey Smith; (2) in 1889-1890 more tombs were opened at Pili by Messrs J. A. R. Munro and H. A. Tubbs; (3) in 1890-1891 extensive trials were made at Salamis, by the same; (4) minor sites were examined at Leontari, Vouno (1888), Amagreti (1888), and Limniti (1891); and in 1893 Hogarth made a surface-survey of the Karpass promontory; and finally, (6) in 1894 the balance was expended by J. L. Myres in a series of trials, to settle special 11 See Cobham, An Attempt at a Bibliography of Cyprus (4th ed., Nicosia, 1900), Appendix, "Cesnola Controversy," p. 54.

points, at Agia Paraskevi, Kalopissia and Larnaca. In 1894 also Dr Richter excavated round *Idalium* and *Tomasius* for the Prussian government: the results, unpublished up to 1902, are in the Berlin Museum. T. Turner entered the British Museum to open numberous tombs, by contract, of the Graeco-Phoenician age, in 1894, at Palæo-Lemesós (*Amathus*), and of the Mycenaean age, in 1894–1895 at Episkopi, in 1895–1896 at Enkomí (near Salamis), and in 1896–1897 on small sites between Larnaca and Limasol.

**MODERN HISTORY**

After the division of the Roman empire Cyprus naturally passed, with all the neighbouring countries, into the hands of the Eastern, or Byzantine, emperors, to whom it continued subject, with brief intervals, for more than seven centuries. Until 641 the island was exceedingly prosperous, but in that year began the period of Arab invasions, which continued intermittently until 795. At the outset the Arabs under the caliph Othman made themselves masters of the island, and destroyed the city of Salamis, which until that time had continued to be the capital. The island was recovered by the Greek emperors and, though again conquered by the Arabs in the reign of Harun ar-Rashid (802), it was finally restored to the Byzantine empire under Nicæus Phocas. Its princes became practically independent, and tyrannized the island, until in 1191 Isaac Comnenus provoked the wrath of Richard I., king of England, by wantonly ill-treating his crusaders. He thereupon wrested the island from Isaac, whom he took captive. He then sold Cyprus to the Knights Templars, who presently resold it to Guey de Lusignan, titular king of Jerusalem.

Guy ruled from 1192 till his death in 1194; his brother Amaury took the title of king, and from this time Cyprus was governed by nearly three centuries by a succession of kings of the Cyprian dynasty, who introduced into the island the feudal system and other institutions of western Europe. During the later part of this period, indeed, the Genoese made themselves masters of Famagusta—which had risen in place of Salamis to be the chief commercial city in the island—and retained possession of it for a considerable time (1576–1644); but it was recovered by King James II., and the whole island was reunited under his rule. His marriage with Caterina Cornaro, a Venetian lady of rank, was designed to secure the support of the powerful republic of Venice, but had the effect after a few years, in consequence of his own death and that of his son James III., of transferring the sovereignty of the island to his new allies. Caterina, feeling herself unable to contend alone with the increasing power of the Turks, was induced to abdicate the sovereign power in favour of the Venetian republic, which at once entered into full possession of the island (1489).

The Venetians retained their acquisition for eighty-two years, notwithstanding the neighbouring hatred of the Turks. Cyprus was now governed by a lieutenant, and the condition of the natives, who had been much oppressed under the Lusignan dynasty, became worse. In 1570 the Turks, under Selim II., made a serious attempt to conquer the island, in which they landed an army of 60,000 men. The greater part of the island was taken without serious resistance; Nicosia, the capital, was taken after a siege of 45 days, and 20,000 of its inhabitants put to the sword. Famagusta alone made a gallant and pro-

of all Cyprus," enlarged subsequently into "archbishop of Justinianna Nova and of all Cyprus," after an enforced expatriation to Justinianopolis in 688. Zeno also gave him the unique privileges of wearing and signing his name in the imperial purple, &c., which were still preserved. A Latin hierarchy was set up in 1196 (an archbishop at Nicosia with suffragans at Limasol, Paphos and Famagusta), and the Greek bishops were made to minister to their flocks in subjection to it. The sees were forcibly reduced to four, the archbishopric was ostensibly abolished, and the bishops were compelled to do homage and swear fealty to the Latin Church. This bondage ceased at the conquest of the island by the Turks: the Latin hierarchy disappeared (the cathedral at Nicosia is now used as a mosque), and the native church emerged into comparative freedom. In 1821, it is true, all the bishops and many of their flocks were put to death by way of discouraging sympathies with the Greeks, but successors were soon consecrated, by bishops sent from Antioch at the request of the patriarch of Constantinople, and on the whole the Church has prospered. The bishops-elect required the bapst of the sultan; but having received this, they enjoyed little independence of his and their suzerains. Since 1787 the bapst has not been given, and the bishops are less influential. The suppressed sees have never been restored, but the four which survive (now known as Nicosia, Paphos, Kition and Kyrenia) are of metropolitan rank, so that the archbishop, whose headquarters, first at Salamis, then at Famagusta, are now at Nicosia, is a primate amongst metropolitans. There are several monasteries dating from the 11th century and onwards; also an archiepiscopal school at Nicosia, founded in 1812 and raised to the status of a "gymnasion" in 1893; and a high school for girls.

CYPSELEUS, tyrant of Corinth (c. 657–627 B.C.), was the son of Aeetion and Labda, daughter of Amphion, a member of the ruling family, the Bacchiae. He is said to have derived his name from the fact that when the Bacchiae, warned that he would prove their ruin, sent emissaries to kill him in his cradle, his mother saved him by concealing him in a chest (Gr. κρυφές). The story was, of course, a subsequent invention. When he was grown up, Cypselus, encouraged by an oracle, drove out the Bacchiae, and made himself master of Corinth. It is stated that to do this he overcame the people of Corinth by a，并 conduct at Polemarch, in which capacity he had to exact the fines imposed by the law. In the words of Aristotle he made his way through demagogy to tyranny. Herodotus, in the spirit of 5th-century Greeks, which conventionally regarded the tyrants as selfish despots, says he ruled harshly, but he is generally represented as mild, benevolent and so popular as to be able to dispense with a bodyguard, the usual attribute of a tyrant. He pursued an energetic commercial and colonial policy (see CORINTH), and thus laid the foundations of Corinthian prosperity. He may well be compared with the Athenian Peisistratus in these respects. He laid out the large sums thus derived on the construction of buildings and works of art. At the same time he wisely strove to gain the goodwill of the powerful priesthoods of the great sanctuaries of Delphi and Olympia. At Delphi he built a treasure-house for Corinthian votive offerings; at Olympia he dedicated a colossal statue of Zeus and the famous "chest of Cypselus," supposed to be identical with the chest of the Legaion, of which Pausanias (v. 17–18) gives a glowing description. It was of cedar-wood, gold and ivory, and on it were represented the chief incidents in Greek (especially Corinthian) mythology and legend. Cypselus was succeeded by his son Periander.

CYRANO DE BERGERAC, SAVININ (1652–1695), French romance-writer and dramatist, son of Abel de Cyrano, seigneur of Mauvières et de Bergerac, was born in Paris on the 6th of March 1619–1620. He received his first education from a country priest, and had for a fellow pupil his friend and future biographer, Henri Lebret. He then proceeded to Paris to the collège de Beauvais, where he had for master Jean Granger, whom he afterwards ridiculed in his comedy Le Pédant joué (1654). At the age of nineteen he entered a corps of the guards, serving in the campaigns of 1639 and 1640, and began the series of exploits that were to make of him a veritable hero of romance. The story of his adventure single-handed against a hundred enemies is vouchèd for by Lebret as the simple truth. After two years of this life Cyrano left the service and returned to Paris to pursue literature, producing tragedies cast in the orthodox classical mode. He was, however, as a pupil of Gassendi, suspected of thinking too freely, and in the Mort d’Agrippine (1654) his enemies even found blasphemy. The most interesting section of his work is that which embraces the two romances L’Histoire comique des états et du royaume de Cyrvia and L’Histoire comique des états et du royaume de Cyrvia. His ingenious mixture of science and romance has furnished a model for frequent writers, among them Swift and E. A. Poe. It is impossible to determine whether he adopted his fanciful style in the hope of safely conveying ideas that might be regarded as unorthodox, or whether he simply found in romance writing a relaxation from the serious study of physics. Cyrano spent a stormy existence in Paris and was involved in many duels, and in quarrels with the comedian Montfleury, with Scaron and others. He entered the household of the duc d’Arpajon as secretary in 1653. In the next year he was injured by the fall of a piece of timber, as he entered his patron's house. Arpajon, perhaps alarmed by his reputation as a free-thinker, desired him to leave, and he found refuge with friends in Paris. During the illness which followed his accident, he is said to have been reconciled with the Church, and he died in September 1655.

M. Edmond Rostand's romantic play Cyron de Bergerac (1897), also a comedy, has been very popular among the French and has been translated into many languages. It is based on the life of the real Cyrano de Bergerac, a young man of little importance in his time, who was an amusing and witty man, but who did not achieve great success in his career. His greatest achievement was his relationship with the French king Louis XIV, and it is this relationship that is the subject of the play. The play is a comedy and is written in the style of the period, with its emphasis on wit and charm. It has been a popular play in France and has been performed in many different countries around the world. It has also been adapted into other forms of media, including opera and film.
themselves less able to hold their own against the Libyan population. A great revolt of the Jewish settlers in the time of Trajan settled the fate of Cyrene and Barca; the former is mentioned by Ammianus Marcellinus in the 4th century a.d. as "urbs deserta," and Synesius, a native, describes it in the following century as a vast ruin at the mercy of the nomads. Long before this its most famous article of export, the silphium plant, a representation of which was the chief coin-type of Cyrene, had come to an end. This plant, credited with wonderful medicinal and aromatic properties, has not been certainly identified with any existing species. The similar Thapsia gargarica (Arab. drias), which now grows freely in Cyrenaica, though it has medicinal properties, has not those ascribed to silphium. Henceforward till the Arab invasion (a.d. 641) Apollonia was the chief city, with Berenice and Potlemais next in order. After the conquest by Amr ibn el-'Asi, inland Cyrenaica regained some importance, lying as it did on the direct route between Alexandria and Kairuan, and Barca became its chief place. But with the substitution of Ottoman for Arab empire, resulting in the virtual independence of both Egypt and Tripoli, the district lying between them had become anarchical. At the end of the Ottoman period after Mahmud II. had resumed direct control over Tripoli (1835), and in the middle of the 19th century Cyrenaica was still free of the Turks that Sheik Ali ben-Senessi chose it as the headquarters of his nascent dervish order. All over the district were built Sensusi convents (zawia), which still exist and have much influence, although the headquarters of the order were withdrawn about the year 1855 to Jarabub, and in 1895 to Kufra, still farther into the heart of Africa. In 1875 the district, till then a sanjak of the vilayet of Tripoli, was made to depend directly on the Ministry of the Interior at Constantinople; and the Senussites soon ceased to be de facto rulers of Cyrenaica. Their preserves have now been still further encroached upon by a number of Cretan Moslem refugees (1901-1902). This is not the first effort made by Turkey to colonize Cyrenaica. In 1860 Ali Riza Pasha of Tripoli tried to induce settlers to go to Bomba and Tobruk; and in 1888 an abortive effort was made to introduce Kurds. To protect the Cretans the Ottoman government has extended the civil administration and created several small garrisoned posts. The district is accordingly safer for Europeans than it was; but these still find themselves ill received. The Ottoman officials discourage travel in the interior, partly from fear of the Senussites, partly from suspicions, excited by the lively interest manifested by Italy in Cyrenaica.

At the present day we understand by Cyrenaica a somewhat larger district than of old, and include ancient Marmarica up to the head of the gulf of Sollum (Catabathmus Magnus). The whole area is about 30,000 sq. m., and has some 250,000 inhabitants, inclusive of nomads. Projecting like a bastion into the Mediterranean at a very central point, Cyrenaica seems intended to play a commercial part; but it does not do so to any extent because of (1) lack of natural harbours, Bengazi and Derna having only open and dangerous roads (this is partly due to coastal subsidence; ancient ports have sunk); (2) the difficulty of the desert routes behind it, wells being singularly deficient in this part of the Sahara. The ivory and feather caravans from Wadai and Borkou have latterly discontinued it altogether. Consequently Cyrenaica is still in a very backward and barbarous state and largely given up to nomad Arabs. There are only two towns, Bengazi and Derna, and not half a dozen settlements besides, worthy to be called villages. In many districts the Senussi convents supply the only settled element, and the local Bedouins largely belong to the Order. There are no roads in the province, and very little internal communication and trade; but a wireless telegraphic system has been installed in communication with Rhodes; and there is a line from Bengazi to Tripoli.

Geologically and structurally Cyrenaica is a mass of Miocene limestone tilted up steeply from the Mediterranean and falling inland by a gentle descent to sea-level again at the line of depression, which runs from the gulf of Sdora through Ajulu to Siwa.

This mass is divided into two blocks, the higher being the western Jebel Akhdar, on which Cyrene was built (about 1800 ft.); the lower, the eastern Jebel el-Akahab, the ancient Marmaric highlands (700 ft.). There is no continuous littoral plain, the longest strip running from the recess of the Syrtis round past Bengazi to Tolmeita. Thereafter, except for deltaic patches at Marsa Susa and Derna, the shore is all precipitous. Jebel Akhdar, being without "faults," has no deep internal valleys, and presents the appearance of downs: but its seaward face is very deeply eroded, and deep circular sinkings (swallow-holes) are common. There is much forest on its northward slopes, and good red earth on the higher parts, which bears abundant crops of barley; much desired by European malsters. Plenty of springs issue on the highlands, and wide expanses of grassy country dotted with trees like an English park are met with. Here the Bedouins (mostly Beni Hassa) pasture flocks and herds, amounting to several million head. The climate is temperate and the rainfall usually adequate, but one year in five is expected to be dry. The southward slopes fall through over-chiseling pasture lands to sheer desert (mostly Cyrenaica). The ancient name of this high plateau, the Jebel Akhdar, and the desert comes right down to the sea in Marmarica, whose few inhabitants are more concerned with salt-collecting and sponge fishing than with agriculture. They have, however, the only good ports on the whole coast, Bomba and Tobruk. Much might be made of Cyrenaica by judicious colonization. All kinds of trees grow well, from the date palm to the oak; and there are over 200,000 wild olives in the country. The conditions in general are very like those of central Italy, and there is ample room for new settlers.

The best modern work is by Francesco S. Carli, to illustrate Camperio and Haimann's Report, in Petermann's Mitth., (1881); and Sheet No. 2 of Carte de l'Afrique (Service géog. de l'armée, 1892).

(D. G. H.)

CYRENAICA, a Greek school of philosophy, so called from Cyrene, the birthplace of the founder, Aristippus (q.v.). It was one of the two earliest Socratic schools, and emphasized one side only of the Socratic teaching (cf. CYNICS). Socrates, although he held that virtue was the only human good, admitted to a certain extent the importance of its utilitarian side, making happiness at least a subsidiary end of moral action (see ETHICS). Aristippus, on the other hand, reduced the sole end of human life to the pursuit of the "good" (aretai), which was held to be in proportion to the "wealth of sense" or "wealth of sensation" (Greek这个词' ") that a person enjoyed in the present. The Cyrenaical theory of well-being is based on this factor in existence, denying to virtue any intrinsic value. Logic and physical science they held to be useless, for all knowledge is immediate sensation (see PROTAGORAS). These sensations are motions (ναρύχοι) which (1) are purely subjective, and (2) are painful, indifferent or pleasant, according as they are violent, tranquil or gentle. Further they are entirely individual, and can in no way be described as constituting absolute objective knowledge. Feeling, therefore, is the only possible criterion of knowledge and of conduct. "Our modes of being affected (παρθύοντα) alone are knowable." Thus Cyrenaicism goes beyond the critical scepticism of the Sophists and deduces a single, universal aim for all men, namely pleasure. Furthermore, all feeling is momentary and homogeneous. It follows (1) that past and future pleasure have no real existence for us, and (2) that among present pleasures there is no distinction of kind, but
only of intensity. Socrates had spoken of the higher pleasures of the intellect; the Cyrenaics denied the validity of this distinction and said that bodily pleasures being more simple and more intense are to be preferred. Momentary pleasure (μόλις ὑπόκουρος ζῶν), preferably of a carnal kind, is the only good for man. Yet Aritippus was compelled to admit that some actions which give immediate pleasure entail more than their equivalent of pain. This fact was to him the basis of the conventional distinction of right and wrong, and in this sense he held that regard should be paid to law and custom. It is of the utmost importance that this development of Cyranesian hedonism should be fully realized. To overlook the Cyrenaic recognition of social obligation and the hedonistic value of altruistic emotion is a very common expedient of those who are opposed to all hedonistic theories of life. Like many of the leading modern utilitarians, they combined with their psychological distrust of popular judgments of right and wrong, and their firm conviction that all such distinctions are based solely on law and convention, the equally unwavering principle that the wise man who would pursue pleasure logically must abstain from that which is usually denominated "wrong" or "unjust." This idea, which occupies a prominent position in systems like those of Bentham, Volney, and even Paley, was evidently of prime importance at all events to the later Cyrenaics.

Developing from this is a new point of practical importance to the hedonism of the Cyrenaics. Aritippus, both in theory and in practice, insisted that true pleasure belongs only to him who is self-controlled and master of himself. The truly happy man must have φθορά (prudence), which alone can save him from falling a prey to mere passion. Thus, in the end, Aritippus, the founder of the purest hedonism in the history of thought, comes very near not only to the Cynics, but to the more cultured hedonism of Epicurus and modern thinkers. Theodorus, held even more strongly that passing pleasure may be a delusion, and that permanent tranquillity is a truer end of conduct. Hecesias denied the possibility of real pleasure and advocated suicide as ensuring at least the absence of pain. Anniceris, in whose thought the school reached its highest perfection, declared that true pleasure consists sometimes in self-sacrifice and that sympathy in enjoyment is a real source of happiness. Other members of the school were Areti, wife of Aritippus, Aristippus the younger (her son), Bio and Euhemerus.

The Cyrenaic ideal was, of course, utterly alien to Christianity, and, in general, subsequent thinkers found it an ideal of hopeless pessimism. Yet in modern times it has found expression in many ethical and literary works, and it is common also in other ancient non-Hellenic literature. There are quatrains in the Rubaiyat of Omar Keynes and pessimistic verses in Ecclesiastes which might have been uttered by Aritippus. ("Then I commended mirth, because a man hath no better thing than to eat and to drink and to be merry; for that shall abide with him of his labour the days of his life which God giveth him under the sun.") So in Byron and Heine, and, in a sense, in Walter Pater (Marpessa-the heroine-figure of whom there is the same tendency to seek refuge from the intellectual cul-de-sac in frankly aesthetic satisfaction. Thus Cyrenaicism did not entirely vanish with its absorption in Epicureanism.

CYRENE [mod. Ain Shuhat-Grenna], the original capital of ancient Cyrenaica (q.v.) and one of the greatest of Greek colonies. The Theraean story of its foundation, as told by Herodotus, runs thus. Battus (whose true Greek name seems to have been Aristoteles), a native of Thera (Santorin), itself a Laconian colony, was hidden by the Delphic oracle, if he wished to put an end to domestic dissensions, to lead a portion of the citizens to Libya and build a city in a "place between waters." (For other stories see Battus.) By this he understood an island, and therefore established his followers on the barren islet of Platea in the gulf of Bomba. The colony being unsuccessful made further application to the oracle and was bidden to transfer itself to the mainland. The Libyan barbarians reported that a fertile and well-watered district lay to the west and were induced to act as guides. They brought the Greeks through forests to high ground from various points of which issued springs, and Battus, recognizing "a place between waters," began to build. This was in the middle of the 7th b.c.

The result was Cyrene, so called (it was said) from a local nymph, who has been shown by Studniczka to have been a Nature goddess, like the Greek Artemis. The point first occupied was probably the hill above the "Apollo" fountain on the west; and there was erected the fortress-palace of the Battidae, who continued to rule the colony for eight generations. The founding Libyans were conciliated and given a position similar to that of Laconian perioci, and intermarriage between them and Greeks became so frequent that the colony rapidly assumed a somewhat hybrid character, and while being one of the centres of Hellenic culture, showed barbarian characteristics of violence and luxury. Battus I. reigned c. 630 to 590 b.c. and was succeeded by his son Arcesilus (c. 590—574) of whom nothing is known. The kings henceforth bore alternately the names Battus and Arcesilus, of which the first is said to be simply the native Libyan word for "king"; the latter, of course, Greek. This fact suggests that some compromise with the natives had been come to, resulting, perhaps, in an alternation of the supreme office. Under Battus II. (570 b.c.) a fresh band of settlers was invited from Greece, and the colony tended to become henceforth more maritime and democratic. Its port, Apollonia (Marsa Sues), now rose to importance; and a second (winter) port was created at Naustathmos (Marsa Hilal) about 15 m. E. behind a sheltering cape. Fine roads were cut through the rock connecting these harbours with the capital. Trouble followed, however, with the Libyans, who saw themselves robbed in favour of the new settlers, and they called in Egyptian help; but the force sent by Apries was defeated near the spring Theste, and presently Amasis of Egypt made peace and took a Battidae princess to wife. Under Arcesilus II. (c. 560—550) domestic dissensions and Libyan revolt led to the founding of a rival inland city, Barca, and a severe defeat and massacre. These misfortunes, coupled with the fact that Battus III. was thought to have disgraced the house by his lameness, prompted the Cyrenaeans to send to Delphi for more advice, and as a result Demonax of Mantinea arrived as arbitrator and framed a constitution limiting the monarchy and dividing the citizens tribally according to the date of their settlement and their place of origin. Further attempts of the Battidae (e.g. of Pherytina, wife of Battus III., and Arcesilus his son) to annul this constitution, and bitter family dissensions, brought about a Persian invasion and finally the extinction of the dynasty about 450 b.c. A republic of more or less Spartan type succeeded, but it was often interrupted by tyrannies; and having made submission by embassy to Alexander in 331, Cyrene passed under Ptolemaic domination ten years later. From this epoch dates a decline which was due to economic causes (see Cyrenaica) and to the Ptolemaic policy of favouring easily controlled harbour-towns rather than an inland place like Cyrene, whose ancient factions still continued to give trouble under the earlier Ptolemies. Apollonia and Berenice gradually superseded Cyrene and Barca respectively, being more in touch with Greece and less exposed to the hostile nomad Libyans, who increased in boldness and power: but Cyrene continued to be a great city after it had passed to Rome (96 b.c.), and up to the reign of Trajan, when a Jewish revolt and the repressive measures taken by the imperial government dealt it an irreparable blow. Ere Christianity became the religion of the empire, it was largely a ruin, and henceforward to the epoch of Arab conquest (A.D. 641) its Greek life gradually deserted it for Apollonia. At its
acme Cyrene is said to have had over 100,000 inhabitants. It was noted among the ancients for its intellectual life. Its medical school was famous, and it numbered among its celebrities Callimachus the poet, Carneades, the founder of the New Academy at Athens, Aristippus, a pupil of Socrates and the founder of the so-called Cyrenaics (q.v.), Eratosthenes the polyhistor, and Synesius, one of the most elegant of the ancient Christian writers.

The first account of the site in modern times seems to be that of M. le Maire, who was French consul at Tripoli from 1703 to 1708, and twice visited Cyrene. Paul Lucas was there in 1710, and again in 1723, and Dr Thomas Shaw in 1738; an Italian, Dr A. Cervelli, who was there in 1812, furnished some information to the Société de Géographie of Paris; and P. Della Cella published an account of his visit, made in 1817. In 1821-1822 important explorations were made by Lieutenant F. W. Beechey, R.N.; and he was almost immediately followed by a French artist, M. J. R. Pacho, whose pencil preserved a number of interesting monuments that have since disappeared. L. Delaporte, French consul at Tangier, and Vattier de Bourville, came next in order of time. H. Barth, the famous African traveller, published an account of his investigations in his "Wanderungen durch die Küstenländer des Mittelmeers", 1849, and James Hamilton, who was there in 1851, described the place in his "Wanderings in N. Africa." In 1861 excavations were made on behalf of the British Museum by Lieuts. R. Murdoch Smith, R.E., and E. A. Porcher, R.N., the results of which are detailed in their valuable "Discoveries in Cyrene" (London, 1864). Since that date, owing to the increase of Senussi influence, and the consequent fears of the Ottoman authorities, the site has been very seldom visited. The Italians, M. Camperio and G. Haimann, leading commercial missions, were there in the eighties, and Mr H. W. Blundell succeeded with a special firman and a strong escort in reaching the place in 1895, but had trouble with the local Senussi Arabs. The prohibition of travel became thereafter more complete, and it has only been overcome by a party from Mr A. V. Armour's yacht "Uotowa," which marched up from Marsa Susa in April 1904, and stayed one night. They found some fifty families of Cretan refugees established at Ain Shahat and a mudir with a small guard on the spot: but no inhabited houses, except the Senussi convent and the mudirija. Cretans and Arabs live in the ancient rock-tombs. An Italian senator, Chev. G. de Martino, with two Italian residents at Derna, passed through the place in 1907, and found it in Bedouin hands.

The site lies on the crest of the highland of Jebel Akhdar (about 1800 ft.) and 10 m. from the sea. The ground slopes very gradually south, and being entirely denuded of trees, makes good corn land. The northward slope falls more steeply in a succession of shelves, covered here and there with forest. Ravines surround the site on three sides, and there are at least four springs in its area, of which one, having great volume, has been at all times the attraction and focus of the place. This is the so-called "Fount of Apollo," which issues from a tunnel artificially enlarged, and once faced with a portico. The acropolis was immediately above this on the W., and the main entrance of the city, through which came the sacred processions, passed it. The remains of Cyrene itself are enclosed by a wall having a circuit of about 4 m., of which little remains but the foundations and fragments of two towers; but tombs and isolated structures extend far outside this area. The local Arabs say it takes them six camel-hours to go from one end to the other of the ruins, which they call generally "Greenna" (i.e. Kyrenna). Within the city itself not very much is now to be seen. Below the Apollo fountain on the N. lie a great theatre and the substructures of the main temple of Apollo, both included now in the Senussi convent garden. Above the fountain and by the main road is a smaller theatre. On the E., upon the crown of the plateau, are the sites on which Smith and Porcher placed temples of Bacchus, Venus and Amphitritus, but they are marked only by rubbish heaps. Remains of a large Byzantine church and a much ruined stadium lie to S.E. On the S. are immense covered tanks of Roman date, with remains of the aqueducts which supplied them. On the W. a fine fragment of a tower, the foundations of the acropolis, and a pedestal sculptured on four sides in good 3rd century style, are the only things worth seeing. The Cretan occupation is fast obliterating other traces. The great spectacle, however, which distinguishes the site of Cyrene, is provided by its cemeteries, which for extent, variety and preservation are unparalleled in the classic lands. There is one along each of the approaches to the main gates, but the largest and most splendid lies by the Apolloian road which winds by easy curves up the northern buttresses of the plateau. Here the sculpures rise in tiers one above the other along fully a mile of the way. The most important have pillared façades, Doric, Ionic, and even a hybrid mixture of both orders. Within, they open out either into large halls, leading one out of another with graves in recesses and pits in the floor; or into rock corridors lined with loculi, disposed one above another like pigeon holes. Most of the wall paintings, seen by Beechey and Pacho, have perished or become black with the smoke of troglodytes' fires; but one tomb below the road at about the middle of the cemetery still retains its decoration comparatively fresh, and seems to be that especially described by Smith and Porcher. The scenes are agonistic, i.e. represent funeral games, in which both white and black persons take part, the latter doubtless Libyan periocii: but all wear Greek garments. Several tombs are inscribed and on some external paintings are still faintly visible. The commonest type of grave is a simple pit covered by a gabled lid. These occur by hundreds. But not all the sepulchres are rock-cut: altar tombs and other forms of heros are found built upon plinths of rock. All visible tombs have long ago been violated, but it is probable that there are others still virgin under the talus of the hill side. To discover these and determine the topography of the city, excavation is urgently needed.

Many historical and artistic questions concerning Cyrene remain unsettled, but since the discoveries made in Laconia in 1898, the much disputed "first Senussi war" has been ascribed to Sparta. A good deal of Cyrenian sculpture, all of comparatively late date, was sent to the British Museum by Smith and Porcher. Nothing has yet been found on the site belonging to the great age of the city's independence, the fine vases sent to the British Museum in 1864, by Mr G. Dennis, having been discovered not there, but near Berenice (Bengazi). The latter site, with Ptolemais and Apollonia, has supplied most of the antiquities found lastly in Cyrenaica.

See authorities for CYRENAICA, and F. Studniczka, Kyrene, eine alt-griechische Göttin (1890).

CYRIL (c. 315-350), bishop of Jerusalem, where he was probably born, was ordained a presbyter in 345, and had the instruction of the catechumens entrusted to him. In 350 he was elevated to the see of Jerusalem, and became deeply involved in the dogmatic controversies of his time. His metropolitan, Acacius of Caesarea, inclined to Arianism, while Cyril strongly espoused the Nicene creed and was, in consequence, deposed for a time. On the death of the emperor Constantine he was restored; but on the accession of Valens, an Arian emperor, he had once more to resign his post till the accession of Theodosius permitted him to return finally in peace in 379. He attended the second ecumenical council held at Constantinople in 381, where he was received with grateful acclamations for his sufferings in defence of orthodoxy. Cyril was even more conspicuous as a pastor than as a controversialist, and this is seen in his one important work—his twenty-three addresses to catechumens delivered in A.D. 348. The first eighteen of these were meant for candidates for baptism; they deal with general topics like repentance and faith, and then expound in detail the baptismal creed of the Jerusalem church. The remaining five addresses were spoken to the newly-baptized in Easter week and explain the mysteries and ritual of baptism, confirmation and the Eucharist. These lectures are said to be "the first complete presentation of the teaching of the church on this matter, and are particularly interesting for the insights which they give us both into the creed-forms of the early church and the various ceremonies of initiation constituting baptism in the 4th century. The evidence which Cyril supplies to the
Jerusalem use is supplemented by the S. Siluica peregrinatio, dating from a generation later. Other tracts and homilies have been ascribed to Cyril of Jerusalem, but they are of doubtful genuineness.

CYRIL (376-444), bishop of Alexandria, a more distinguished father of the church than his namesake of Jerusalem, was born in 376, and died in 444. Becoming patriarch of Alexandria about 412, he soon made himself known by the violence of his zeal against Jews, pagans and heretics or supposed heretics alike. He had hardly entered upon his office when he closed all the churches of the Novatians and seized their ecclesiastical effects. He assailed the Jewish synagogues with an armed force, drove the Jews in thousands from the city, and exposed their houses and property to pillage. The prefect of Egypt, Orestes, who endeavoured to withstand his furious zeal, was in turn denounced himself, and had difficulty in maintaining his ground against the fury of the Christian multitude. It was during one of the violent commotions kindled by the strife of these parties in Alexandria that the illustrious Hypatia, famed for her beauty and her eloquent advocacy of the Neo-Platonic philosophy in opposition to Christianity, was murdered. Her murder has been attributed to the direct instigation of the patriarch himself; but this charge is held to be baseless by others, although there can be no doubt that “the perpetrators were officers of his church,” and undoubtedly drew encouragement from his own violent proceedings. Hypatia was a friend of Orestes, and the hostility that existed between the prefect and the patriarch overlapped towards her, and undoubtedly led to her destruction.

But Cyril’s violence was not merely confined to those who might be considered enemies of the church. He inherited from Theophilus, his uncle and predecessor in the see of Alexandria, a strong aversion to John Chrysostom, the noble bishop of Constantinople, and even after his death opposed for a time all attempts to remove the unjust sentence of condemnation which had been passed upon him. Afterwards he so far yielded to remonstrances as to allow the name of Chrysostom to appear in the list of distinguished martyrs and bishops mentioned in the prayers of his church. These names were inserted in what were called “diptychs” (ἐπτυχας νεκρων), or two-leaved tablets preserved in the churches—a usage which the Greek Church has continued to this day.

Cyril thus represents—a though he differs largely from his predecessors—the tendencies dominant at Alexandria in the 5th century, and their antagonism to the Antiochean school. The story of his opposition to Nestorius at the council of Ephesus in 431 is told elsewhere (see Nestorius). He himself incurred the charge of heresy from the oriental bishops. Satisfied, however, with the deprivation and exile of his opponent, he returned to Alexandria in triumph as the great champion of the faith, and thence continued, by the “unscrupulous use of all the means at his command,” the theological strife for years. He was a bitter opponent of the great Antiochean expositor and apologist Theodoret.

Altogether Cyril presents a character not only unamiable, but singularly deficient in the graces of the Christian life. His style of writing is as objectionable as his character and spirit. Yet he takes high rank as a dogmatic theologian, and those who seek precise and rigid definitions of orthodox belief conjoined with tenacity of conviction find him indispensable. In addition to his Twelve Apostenmillenium and the defense of the same, he wrote five other books against Nestorius, Thesaurus—a treatise in dialogue form on the Trinity, a book On the Right Way and another On the Incarnation. In other fields—mythical, exegetical and apologetical—he was equally prolific and forceful. He wrote a tract “On worshipping in spirit and in truth” to defend a spiritual interpretation of the Mosaic law, several commentaries, festival-oralations, and a reply to the emperor Julian’s attack on the church. His letters are valuable sources to the student of the Nestorian controversy.

Literature.—The collected edition of J. Aupert (Paris, 1658) formed the basis of Migne’s reprint in vols. 68-77 of the Patro. Graec. Many of the writings have been edited separately (see bibliography in Herzog-Hauck). For an account of his career and his influence see Th. Schmid, Chrysostom (1893). See also P. Kraus, S. Chrys. in der Patrologie (Freiburg, 1894), pp. 335-343; R. L. Ottley’s Doctrine of the Incarnation, ii. 80 ff.; A. Largent’s Études d’histoire eccl., St Cyrille d’Alexandrie et le concile d’Éphèse (Paris, 1892). See also Charles Kingsley’s romance Hypatia.

CYRILIC, the alphabet used by the Orthodox Slavs. It is modelled on the Greek Liturgical Uncial of the 9th century, and its invention is traditionally, though in all probability wrongly, ascribed to the Greek missionary Cyril (d. 869). For an account of its origin and development, with a table of its letters, see Slav.

CYRILLUS, Greek jurist of the 5th century, was professor in the ancient law college of Berytus, and one of the founders of the ecumenical school of jurists (τοις εκκένων διδακτάρεσι) which preceded the succession of Anastasius to the Eastern empire (a.D. 491), and paved the way for Justinian’s legislation. His reputation as a teacher of law was very great; and from the fragments of his works which have been preserved it may be inferred that his merit as a teacher consisted in his going direct to the ancient sources of law, and in interpreting the best writers, such as the commentary of Ulpian on the edict and the Responda Papiniani. He wrote a treatise on definitions (ἐνθυμευμα των διδακτών) in which, according to a statement of his contemporary Patricius, the subject of contracts was treated with superior precision and great method, and which has supplied the materials for many important scholia appended to the first and second titles of the eleventh book of the Basilica. He is generally styled “the great,” to distinguish him from a more modern jurist of the same name, who lived after the reign of Justinian, and who compiled an epitome of the Digest.

CYRTO-STYLE (Gr. κυρος, convex, and στυλος, column), in architecture, a circular projecting portico with columns; like those of the transept entrances of St Paul’s cathedral and the western entrance of St Mark’s, Venice.

CYRUS (Gr. Κωρος; Pers. Kuru-sh; Babyl. Kurush; Hebr. Kōresh), the Latinized form of a Persian name borne by two prominent members of the Achaemenid house.

1. CYRUS THE GREAT, the founder of the Persian empire, was the son of Cambyses I. His family belonged to the clan of the Achaemenidae—in the inscription on the pillars and columns of the palace of Pasargadae (Murbagh) he says: “I am Cyrus the king, the Achaemenid”—the principal clan (φροφρ) of the Persian tribe of the Pasargidae (q.v.). But in his proclamation to the Babylonians (V.R. 35; Sir H. Rawlinson, Journal of the R. Asiatic Soc., n.s., xii., 1880; Schrader, Keilinschriften Bibliothek, iii. 2, 190 ff.; Hagen, in Delitzsch and Haupt, Beiträge zur Assyriologie, ii., 1894, where the chronicle of Nabonidus is also published anew with a much improved translation) he calls his ancestors, Teispes, Cyrus I. and Cambyses I., “kings of Anshan,” and the same title is given to him in the inscription and in the chronicle of Nabonidus of Babylon before his victory over Astyages. Anshan is a district of Elam or Susiana, the exact position of which is still subject to much discussion. As we know from Jeremiah xlix. 34 ff. (cf. Ezekiel xxxii. 24 ff.) that the Elamites suffered a heavy defeat in 506 B.C., it is very probable that the Pasargadyn dynasty Teispes conquered Anshan in this year. Modern authors have often supposed that Cyrus and his ancestors were in reality Elamites; but this
is contrary to all tradition, and there can be no doubt that Cyrus was a genuine Persian and a true believer in the Zoroastrian religion. The account of Herodotus, vii. 70, that the genealogy of Cyrus is given in the same way as in the proclamation of Cyrus himself; Teispes is called here the son of the eponym Achaemenes.

The Persians and the Median empire. Their kingdom cannot have been of large extent, as Nabonidus in a contemporary inscription (Cylinder from Abu Habbah, VR. 64, Schrader, Keilinschriften. Bibliothek, iii. 2, 96), where he mentions his rebellion against Astyages, calls Cyrus “king of Anshan, his (i.e. Astyages’) small servant (vassal).” From this inscription we learn that the rebellion of Cyrus (who seems to have become king in 538 B.C., as Herod. i. 214 gives him a reign of 29 years) began in 553 B.C., and from the annals that in 550 Astyages marched against Cyrus, but was defeated; his troops revolted against him, he was taken prisoner, and Cyrus occupied and plundered Ecbatana. The relation of Ctesias (preserved by Nic. Dam. fr. 66; Anaximenes of Lamprocus in Steph. Byz. s. v. ἱσταργάδας; Strabo xv. p. 729; Poly. Deut. vii. 6. 1, 9, 45) that Cyrus was three times beaten by Astyages and that the decisive battle took place in the mountains of Pasargadae, is certainly in the main historical although Herodotus (i. 127 ff.) only mentions the tradition of the Median general Harpagus and the defeat and captivity of Astyages. In the rebellion the Persian tribes of the Maraphians and Masprians joined the Pasargadae (Herod. i. 125), while the other tribes appear not to have acknowledged Cyrus till after his victory (pears). From then he calls himself “king of the Persians.” The history of Cyrus very soon became involved and quite overgrown with legends. Herodotus (i. 95) tells us that he knew four different traditions about him. One makes him the son of Mandane, a daughter of Astyages (originally evidently by a god), who is exposed in the mountains by his grandfather on the account of an oracle, but suckled by a dog (a sacred animal of the Iranians) and educated by a shepherd; i.e. the myth which we know from the stories of Oedipus, Pers. xvi. Telesphos, Ptol. Deut. iii. 8, and Not. s. v. Ναβονίδος, Seleucus, Sat. Agr. 43; Moses, the Indian hero Krishna, and many others, has been transferred to the founder of the Persian empire. At the same time, the rule of Cyrus and the Persians is legitimated by his family connexion with Astyages. This account is partly preserved in Justin i. 4. 10 (probably from Charon of Lampascus) and in Aelian, Var. Hist. xiv. 42, and alluded to by Herodotus i. 95 and 122. The second account, which Herodotus follows, is a rationalized version of the first, where the dog is changed into a woman (the wife of the shepherd) named Spako (bitoch). In the later part of his story Herodotus is dependent on the family traditions of Harpagus, whose treason is justified by the cruelty with which Astyages had treated him (the story of Atreus and Thyestes is transferred to them). Harpagus afterwards stood in high favour with Cyrus, and commanded the army which subdued the coasts of Asia Minor; his family seems to have been settled in Lydia. In a third version, preserved from Ctesias, Damianus, p. 66 (cf. Diod. vi. 633 C), Cyrus is the son of a poor Mardian bandit Antrataes (the Mardians are a nomadic Persian tribe, Herod. i. 125), who comes as a voluntary slave to the court of Astyages, and finds favour with the king. A Chaldaean sage prophesies to him his future greatness, and another Persian slave, Oeabes, becomes his associate. He flies to Persia, evades the pursuers whom Astyages sends after him, and begins the rebellion. After the victory Oeabes kills Astyages against the will of Cyrus, and afterwards kills himself to evade the wrath of Cyrus. Parts of this story are preserved also in Strabo xv. p. 720, and Justin i. 6. 1-27; 1-7; cf. Ctesias αϕ. Φωτιανον 2-7; many traces of it were afterwards transferred to the story of Ardashir I. (q.v.), the founder of the Sassanian empire. With this version Ctesias and Nicolas have connected another, in which Cyrus is the son of a Persian shepherd who lives at Pasargadae, and fights the decisive battle at this place. The didactic novel of Xenophon, the Cyropædia, is a free invention adapted to the purposes of the author, based upon the account of Herodotus and occasionally influenced by Ctesias, without any independent traditional element. The account of Aeschylus. Pers. 765 ff., is a mixture of Greek traditions with a few oriental elements; here the first king is Medos (the Median empire); his nameless son is succeeded by Cyrus, a blessed ruler, beloved by the gods, who gave peace to all his friends and conquered Lydia, Phrygia, Ionia. Then comes his nameless son, then Mardos (i.e. Smerdis, to whom the name of the Mardians is transferred) who is killed by Artaphernes (i.e. Artaphernes, Herod. iii. 78, one of the associates of Darius), then Maraphis (eponym of the Maraphian tribe), then another Artaphernes, then Darius. The principal events of the later history of Cyrus are in the main correctly stated by Herodotus, although his account contains many legendary traditions. The short excerpt from Ctesias, who Phoebus has preserved, contains useful information, although we must always mistrust him. Of great value are a short notice in the fragments of Berossus and another in the Old Testament. The original sources are very scanty, besides the cylinder containing his proclamation to the Babylonians we possess only a great many dated private documents from Babylon. These serve to fix the chronology, which is here as everywhere quite in accordance with the dates of the canon of Ptolemy.

Soon after the conquest of the Median empire, Cyrus was attacked by a coalition of the other powers of the East, Babylon, Egypt and Lydia, joined by Sparta, the greatest military power of Greece. In the spring of 546 Croesus of Lydia began the attack and advanced into Cappadocia, while the other powers were still gathering their troops. But Cyrus anticipated them; he defeated Croesus and followed him to his capital. In the autumn of 546 Sardis was taken and the Lydian kingdom became a province of the Persians. The famous story of Herodotus, that the conqueror condemned Croesus to the stake, from which he was saved by the intervention of the gods, is quite inconsistent with the Persian religion (see Croesus). During the next years the Persian army under Harpagus suppressed a rebellion of the Lydians under Pactyas, and subjugated the Ionian cities, the Carians and the Lyceans (when the town Xanthus resisted to the utmost). The king of Cilicia (Synnysis) voluntarily acknowledged the Persian supremacy. Why the war with Babylon, which had become inevitable, was delayed until 539, we do not know. Here too Cyrus in a single campaign destroyed a mighty state. The army of Nabonidus was defeated; Babylon itself attempted no resistance, but surrendered on the 10th Tishri (10th of October) 539, to the Persian general Gobryas (Gaborava, see the chronicle of Nabonidus; the name Gobryas is preserved also by Xenophon, Cyrop. v. 4. 24); it is possible that the Chaldaean priests, who were hostile to Nabonidus, betrayed the town. In a proclamation issued after his victory Cyrus guarantees life and property to all the inhabitants and designates himself as the favourite of Marduk, the great local god (Bel, Bel-Merodak). From the Babylonian Cylinder. It is very odd that modern authors have considered this proclamation as inconsistent with the Zoroastrian creed.

From the beginning of 538 Cyrus dates his years as “king of Babylon and king of the countries” (i.e. of the world). With the capital, the Babylonian provinces in Syria fell to the Persians; in 538 Cyrus granted to the Jews, whom Nebuchadrezzar had transported to Babylonia, the return to Palestine and the rebuilding of Jerusalem and its temple (see Jews, § 19). It is probable that Cyrus had fought more than one war against the peoples of eastern Iran; according to Ctesias he had, before the war with Croesus, defeated the Bactrians and the Sacae (in Ferghana; their king Amorges is the eponym of the Amyrgian Sacae, Herod. vii. 64, called by Darius Haumassarks); and the historians of Alexander mention a march through Gedrosia, where he lost his whole army but seven men (Arrian iii. 24, 2; Strabo xv. 722), a tribe Arissae in the Syrmains (in Sijistan), who, on account of the support which they gave him against the Scythians, were called Euegetae (Arrian iii. 27, 4; Diod. xvii. 81: Curt. vii. 3. 1), and a town Cyropolis, founded by him.
on the Jaxartes (Arrian iv. 2. 3; Curt. vii. 6. 16; Strabo xi. 517, called Cyreskhata by Ptolem. vi. 12. 5). In 349, having appointed his son Cambyses king of Babel, he set out for a new expedition against the East. In this war he was killed (Herod.) or mortally wounded (Ctesias). According to Herodotus he attacked the Massagetae beyond the Jaxartes; according to Ctesias, the Derbices, a very barbarous tribe (cf. Strabo xi. 520; Aelian, Var. Hist. iv. 1) on the border of the Caspian, near the Hyrcanians (Strabo xi. 514; Steph. Byz.; Curt. vii. 2. 7; Dion. Perige. 734 ff.; Pomp. Mela iii. 5), or on the Oxus (Plin. vi. 48; Ptolem. vi. 10. 2; Tob. Peuting.). Berosus (op. Euseb. Chron. i. 29) simply says that he fell against the Dahae, i.e. the nomads of the Turanian desert. His death occurred in 528 B.C., as we have a Babylonian tablet from the Adar of the tenth year of Cyrus, i.e. February 528; for in Babylon the first year of Cyrus began in the spring of 538.

In his native district Cyrus had built a city with a palace, called after his tribe Pasargadæ (now Murghab), and here he was buried (see PASARGADÆ). In a short time he, the petty prince of an almost unknown tribe, had founded a mighty empire, which extended from the Indus and Jaxartes to the Aegean and the borders of Egypt. This result shows that Cyrus must have been a great warrior and statesman. Nor is his character without nobility. He excels in the humanity with which he treated the vanquished. He destroyed no town nor did he put the captive kings to death; in Babylonia he behaved like a constitutional monarch; by the Persians his memory was cherished as "the father of the people" (Herod. iii. 89), and the Greek tradition preserved by Aeschylus (cf. above) shows that his greatness was acknowledged also by his enemies. He therefore deserves the homage which Xenophon paid to him in choosing him as hero for his didactic novel.

2. CYRUS THE YOUNGER, son of Darius II. and Parysatis, was born after the accession of his father in 424. When, after the victories of Alcibiades, Darius II. decided to continue the war against Athens and give strong support to the Spartans, he sent in 408 the young prince into Asia Minor, as satrap of Lydia and Phrygia Major with Cappadocia, and commander of the Persian troops, "which gather into the field of Castolos" (Xen. Hell. i. 4. 3; Anab. i. 9. 7), i.e. of the army of the district of Asia Minor. He gave strenuous support to the Spartans; evidently he had already then formed the design, in which he was supported by his mother, of gaining the throne for himself after the death of his father; he pretended to have stronger claims to it than his elder brother Artaxerxes, who was not born in the palace. For this plan he hoped to gain the support of Sparta. In the Spartan general Lysander he found a man who was willing to help him, as Lysander himself hoped to become absolute ruler of Greece by the aid of the Persian prince. So Cyrus put all his means at the disposal of Lysander in the Peloponnesian War, but denied them to his successor Callirhidas; by exerting his influence in Sparta, he brought it about that after the battle of Arginusae Lysander was sent out a second time as the real commander (though under a nominal chief) of the Spartan fleet in 405 (Xen. Hell. ii. 1. 14). At the same time Darius fell ill and called his son to his deathbed; Cyrus handed over all his treasures to Lysander and went to Susa. After the accession of Artaxerxes II. in 404, Tissaphernes denounced the plans of Cyrus against his brother (cf. Plut. Artax. 3) but by the intercession of Parysatis he was pardoned and sent back to his satrapy. Meanwhile Lysander had gained the battle of Aegospotami and Sparta was supreme in the Greek world. Cyrus managed very cleverly to gather a large army by beginning a quarrel with Tissaphernes, satrap of Caria, about the Ionian towns; he also pretended to prepare an expedition against the Pisidians, a mountainous tribe in the Taurus, which was never obedient to the Empire. Although the dominant position of Lysander had been broken in 403 by King Pausanias, the Spartan government gave him all the support which was possible without going into open war against the king; it caused a partisan of Lysander, Clearchus, condemned to death on account of atrocious crimes which he had committed as governor of Byzantium, to gather an army of mercenaries on the Thracian Chersonesus, and in Thessaly Menon of Pharsalus, head of a party which was connected with Sparta, collected another army.

In the spring of 401 Cyrus united all his forces and advanced from Sardis, without announcing the object of his expedition. By dexterous management and large promises he overcame the scruples of the Greek troops against the length and danger of the war; a Spartan fleet of thirty-five triremes sent to Cilicia opened the passes of the Amanus into Syria and conveyed to him a Spartan detachment of 700 men under Cheirisophus. The king had only been warned at the last moment by Tissaphernes and gathered an army in all haste; Cyrus advanced into Babylonia, before he met with an enemy. Here ensued, in October 401, the battle of Cumana. Cyrus had 20,400 Greek hoplites and 2,500 peltasts, and besides an Asiatic army under the command of Artaius, for which Xenophon gives the absurd number of 100,000 men; the army of Artaxerxes he puts down at 900,000. These numbers only show that he, although an eyewitness, has no idea of large numbers; in reality the army of Cyrus may at the very utmost have consisted of 30,000, that of Artaxerxes of 40,000 men. Cyrus saw that the decision depended on the fate of the king; he therefore wished Clearchus, the commander of the Greeks, to take the centre against Artaxerxes. But Clearchus, a tactician of the old school, disobeyed. The left wing of the Persians under Tissaphernes avoided a serious conflict with the Greeks; Cyrus in the centre threw himself upon Artaxerxes, but was slain in a desperate struggle. Afterwards Artaxerxes pretended to have killed the rebel himself, with the result that Parysatis took cruel vengeance upon the slayer of her favourite son. The Persian troops dared not attack the Greeks. Another account has it that Cyrus died in the interior, beyond the Tigris, and tried to annihilate them by treachery. But after their commanders had been taken prisoners the Greeks forced their way to the Black Sea. By this achievement they had demonstrated the internal weakness of the Persian empire and the absolute superiority of the Greek arms.

The history of Cyrus and of the retreat of the Greeks is told by Xenophon in his Anabasis (where he tries to veil the actual participation of his own expedition); but the other accounts, probably from Sophanetus of Sthymalus, was used by Ephorus, and is preserved in Diodor. xiv. 19 ff. Further information is contained in the excerpts from Ctesias of Phorius; cf. also Plutarch's life of Artaxerxes. The character of Cyrus is highly praised by the ancients, especially by Xenoph. (cf. also his Life of Cyrus, c. W.); and certainly he was much superior to his weak brother in energy and as a general and statesman. If he had ascended the throne he might have regenerated the old empire for a while, or at least have prolonged the existence of Artaxerxes II. (See also Persia: Ancient History, (Ed. M.)

CYSTOFLAGELLATA (so named by E. Haeckel), a group of Mastigophorous Protozoa, distinguished from Flagellata by their large size (0.15-1.5 mm.), and their branched endoplasm, recalling that of Trachelium among Infusoria, within a firm ecutosomal bounded by a strong cuticle. Nutrition is holozoic, a deep groove leading down to a mouth and pharynx. A long fine flagellum arises from the pharynx in Noctiluca (E. Suriyal) Leptodiscus and (R. Hertwig); and in the former genus, a second flagellum, thick, long and transversely striated, rides farther out, in the groove; this was likened by E. R. Lankester to a proboscis, whence his name of Rynchoflagellata, which we discard as unnecessary and posterior to Haeckel's. Noctiluca has thus the form of an apple with a long stalk. Leptodiscus (R. Hertwig) has the form of a mouse with a prominent proboscis; it is mensiform with the thin contractile margin produced inwards like a velum on the concave side, while the mouth is on the convex surface and the single flagellum springs from a blind tube on the same surface. Craspedodella (C. A. Kofoid), the third genus, is still more medusiform, with a broad velum, and the mouth in a convex central protrusion of the roof of the bell; and a thick flagellum springs from a blind tube on the convex surface. All three genera are pelagic and phosphorescent, this property being seated in the ectoplasm; Noctiluca miliaris is indeed the chief source of the phosphorescence of our summer seas. O. Blümich, like other writers, regards the Cystoflagellata as closely allied to the Dinoflagellata, the small flagellum
The reproduction of *Noctiluca* has been fairly made out; in the adult state it divides by fission down the oral groove; as a preliminary the external differentiations disappear, and the nucleus divides by modified mitosis; then the external organs are regenerated. Under circumstances not well made out, the form (figs. 5, 6). The metamorphosis of these has not yet been observed.

**Cystolith** (Gr. κύστης, cavity, and κλῦς, stone), a botanical term for the inorganic concretions, usually of calcium carbonate, formed in a cellulosic matrix in special cells, generally in the leaf of plants of certain families, e.g. _Ficus elastica_, the indiarubber plant.

**Cythera** (mod. Cerigo), but still officially known as Cythera, one of the Ionian islands, situated not less than 150 m. from Zante, but only about 8 m. from Cape Malea on the southern coast of Greece. Its length from N. to S. is nearly 20 m., and its greatest breadth about 12; its area is 114 sq. m. The surface is rocky and broken, but streams abound, and there are various parts of considerable fertility. Two coves, of imposing dimensions, and adorned with stalactites of great beauty, are the most notable among its natural peculiarities; one is situated at the seaward end of the Glen of the Mylopotamus, and the other, named Santa Sophia, about two hours' ride from Capsali (Kapsali). Less of the ground is cultivated and more of it is in pasture land than in any other of the seven islands. Some wine and corn are produced, and the quality of the olive oil is good. The honey is still highly prized, as it was in remote antiquity; and a considerable quantity of cheese is manufactured from the milk of the goats. Salt, flax, cotton and currants are also mentioned among the produce. The people are industrious, and many of them seek employment as labourers in the Morea and Asia Minor. Owing to emigration, the population appears to be steadily diminishing, and is now only about 6000, or less than half what it was in 1857. Unfortunately the island has hardly a regular harbour on any part of the coast; from its situation at the meeting, as it were, of seas, the currents in the neighbourhood are strong, and storms are very frequent. The harbour of Capsali is at the mouth of the eastern side of the island. The principal village is Capsali, a place of about 1500 inhabitants, at the southern extremity, with a bishop, and several convents and churches; the lesser hamlets are Modari, Potamo and San Nicolò.

There are comparatively few traces of antiquity, and the identification of the ancient cities has been disputed. The capital, which bore the same name as the island, was at Paleokastro, about 3 m. from the present port of Avlemona. In the church of St Kosmas are preserved some of the archaic Doric columns of the famous temple of Aphrodite of Cythera, whose worship had been introduced from Syria, and ultimately spread over Greece. According to the accepted story, it was here that the goddess first landed when she emerged from the sea. At a very early date Cythera was the seat of a Phoenician settlement, established in connexion with the purple fishery of the neighbouring coast; it is said that it was therefore called Porphyris (cf. Pliny iv. 18, 10). For a time dependent on Argos, it became after 350 B.C., an important part of the Sporades, who annually despatched a governor named the Cytherodice. In the Peloponnesian war, Nikias occupied the island, but in 421 it was recovered by Sparta. Its modern history has been very much the same as that of the other Ionian islands; but it was subject to Venice for a much shorter period—from 1717 to 1707.

See the works referred to under CEPHALONIA, and also Weil, in _Mittheil. d. deutsch. Inst. zu Athen_ (1880), pp. 224-243.

**Cytisine** (_Ulexin, Sophorin_), _C_{18}H_{22}N_{2}O_{3}, _an alkaloid discovered in 1818 by J. B. Chevreul in the seeds of laburnum (_Cytisus Laburnum_) and isolated by A. Husemann and W. Marmè in 1865 (Zeit. f. Chemie, 1865, 1.p. 161). It is also found in the seeds of furze (_Ulex europaeus_), _Sophora tormentosa_, and _Euchresta hirsutifolia_. It is extracted from the seeds by an
alcoholic solution of acetic acid, and forms large crystals which melt at 153° C., and are easily soluble in water, alcohol, and chloroform. It is a secondary and tertiary di-acid base, and is strongly alkaline in its reaction. Hydrogen peroxide oxidizes it to oxyctysine, C₄H₆N₂O₃, chronic acid to an acid, C₆H₅NO₂, and potassium permanganate to oxalic acid and ammonia. It acts as a violent poison.

CYTOLOGY (from κύτως, a hollow vessel, and λήγειν, science), the scientific study of the "cells" or living units of protoplasm (q.v.), of which plants and animals are composed. All the higher, and the great majority of the lower, plants and animals are composed of a vast number of these vital units or "cells." In the case of many microscopic forms, however, the entire organism, plant or animal, consists throughout of a single cell. Familiar examples of these "cells" are bacteria and diatoms among the plants, and Foraminifera and Infusoria among the animals. In all cases, however, whether the cell-unit lives freely as a unicellular organism or forms an integral part of a multi-cellular individual, it exhibits in itself all the phenomena characteristic of living things. Each cell assimilates food material, whether this is obtained by its own activity, as in the majority of the protozoa, or is brought, as it were, to its own door by the blood stream, as in the higher Metazoa, and builds this food material into its own substance, a process accompanied by respiration and excretion and resulting in growth. Each cell exhibits in greater or less degree "irritability," or the power of responding to stimuli; and finally each cell, at some time in its life, is capable of reproduction. It is evident therefore that in the multicellular forms all the complex manifestations of life are but the outcome of the co-ordinated activities of the constituent units. The latter are regarded, as Virchow has termed them, "vital units." It is therefore in these vital units that the explanation of vital phenomena must be sought (see Physiologic). As Verworn 1 said, "It is to the cell that the study of every bodily function sooner or later drives us. In the muscle cell lies the problem of the heart beat and that of muscular contraction; in the gland cell reside the causes of secretion; in the epithelial cell, in the white blood corpuscle, lies the problem of the absorption of food, and the secrets of the mind are hidden in the ganglion cell." So also the problems of development and inheritance have shown themselves to be cell problems, while the study of disease has produced a "cellular pathology." The most important problems awaiting solution in biology are cell problems.

Historical.—The cell-theory ranks with the evolution theory in the far-reaching influence it has exerted on the growth of modern biology; and although there were already some signs of the growth of the "cell" idea in the work of the early investigators, the growth of the theory is due to the work of a few great men who have given it a firm theoretical basis, and to the achievements which in recent years have been made with these fundamental ideas. The cell-theory, in its form, however, different from that in which we now know it—was originally suggested by the study of plant structure; and the first steps to the formulation, many years later, of a definite cell-theory, were made as early as the later part of the 17th century by Robert Hooke, Marcello Malpighi and Nehemiah Grew. Hooke (1665) noted and described the vascular nature of cork and similar vegetable substances, and designated the cavities by the term "cells." A few years later Malpighi (1674) and Grew (1682), still of course working with the low power lenses alone available at that time, gave a more detailed description of the finer structure of plant tissue. They showed that it consisted in part of little cell-like cavities, provided with firm cell-walls and filled with fluid, and in part of long tube-like vessels. A long time passed before the next important step was made by C. L. Treviranus, 2 who, working on the growing parts of young plants, showed that the tubes and vessels of Malpighi and Grew arose from cells by the latter becoming elongated and attached end to end, the intervening walls breaking down; a conclusion afterwards confirmed by Hugo von Mohl (1830). It was not, however, until the appearance of Matthias Jakob Schleiden's paper Beiträge zur Phylogenie (1838) that we have a really comprehensive treatment of the cell, and the formulation of a definite cell-theory for plants. It is to the wealth of correlated observations and to the philosophic breadth of the conclusions in this paper that the subsequent rapid progress in cytology is undoubtedly to be attributed. Schleiden in this paper attempted to solve the problem of the mode of origin of cells. The nucleus (side infra) of the cell had already been discovered by Robert Brown (1831), who, however, failed to realize its importance. Schleiden utilized Brown's discovery, and although his theory of phylogenesis is based on erroneous observations, yet the great importance which he rightly attached to the nucleus as a cell-structure made it possible to extend the cell-theory to animal tissues also. We may therefore date the beginning of the cytologic epoch from this short but epoch-making paper. Comparisons between plant and animal tissues had already been made by several workers, among others by Johannes Müller (1835), and by F. G. J. Henle and J. E. Purkinje (1837). But the first real step to a comprehensive cell-theory to include animal tissues was made by Theodor Schwann. This author, stimulated by Schleiden's work, published in 1839 a series of Mikroskopische Untersuchungen über die Übereinstimmung in der Struktur und dem Wachstum der Tiere und Pflanzen. This epoch-making work ranks with that of Schleiden in its stimulating influence on biological research, and in spite of the greater technical difficulties in the way, raised animal cytology at one blow to the position already, and so laboriously, acquired by plant cytology. In the animal cell it is the nucleus and not the cell-wall that is most conspicuous, and it is largely to the importance which Schwann, following the example of Schleiden, attached to this structure as a cell substance that came to form a basis in the cytology of the animal, and in the short time that his work is due. Another feature determining the success of Schwann's work was his selection of embryonic tissue as material for investigation. He showed that in the embryo the cells all closely resemble one another; only becoming later converted into the tissue elements—nerve cells, muscle cells and so forth—as development proceeded; just as a similar mode of investigation had enabled Treviranus to trace the origin from typical cells of the vascular tissue in plants more than 30 years previously. And just as Treviranus showed that there was a union of cells to form the vessels in plants, so Schwan now showed that a union of cells frequently occurred in the formation of animal tissues. So great was the stimulus given to cytological research by the work of Schleiden and Schwann that these authors are often referred to as the founders of the cell-theory. Their theory, however, differed very greatly from that of the present time. So early did they to the birth of new cells arise by a form of "crystalization" (from a formative "mother liquor" or "cytoblastema" (side infra), but they both defined the cell as a "vesicle" provided with a firm cell-wall and with fluid contents. The cell-wall was regarded as the essential cell-structure, which by its own peculiar properties controlled the cell-processes. The work of Schleiden and Schwann marks the close of the first period in the history of the cell-theory—the period dominated by the cell-wall. The subsequent history is marked by the gradual recognition of the importance of the cell-contents. Schleiden had noticed in the plant cell a finely granular substance which he termed "plant slime" (Pflanzenschleim). In 1846 Hugo von Mohl applied to this substance the term "protoplasm," a term already used by Purkinje six years previously for the formative substance of young animal embryos. Mohl showed that the young plant cell was at first completely filled by the protoplasm, and that only later, by the gradual accumulation of vacuoles in the interior, did this substance come to form a thin layer on the inner surface of the cell-wall. Mohl also described the spontaneous movement of the protoplasm, a phenomenon already noted by Schleiden for his plant slime, and originally discovered by Bonaventura Corti in 1772 for the cells of Chara, and rediscovered in 1807.

1 Allgemeine Physiologie, p. 53 (1895).
2 Vom unwandelbaren Bau der Gewebe (1866).
by Treviranus. Not only was attention thus gradually directed to the importance of the cell-contents, but observations were not lacking even in the plant kingdom, tending to weaken the importance hitherto attached to the cell-wall. Among these may be mentioned Cohn’s observation that in the reproduction of Algal forms the proplastom contracts away from the cell-wall and escapes as a naked “spore.” Similarly in the animal kingdom instances began to be noted in which no membrane appeared to be present (Kolliker, 1845; Bischoff, 1842), and for some time it was hotly debated whether these structures could be regarded as true cells. As a result of the resemblance between the streaming movements in these apparently naked cells (e.g. lymphocytes) and those seen in plant cells, R. Remak was led (1852-1853) to apply M. Mohl’s term “protoplasm” to the substance of these animal cells also. Similarly Max Schultz (1853) and H. A. de Bary (1859), as a result of the study of unicellular animals, came to the conclusion that the substance of these organisms, originally termed “Sarcode” by F. Dujardin, was identical with that of the plants. Numerous workers now began to recognize the subordinate position of the cell-wall (e.g. Nägeli, Alexander Braun, Leydig, Kolliker, Cohn, de Bary &c.), but it is to Max Schultz above all that the credit is due for having laid the foundation of the modern conception of the cell—a conception often referred to as the proto-plasmic-theory in opposition to the cell-theory of Schleiden and Schwann. Max Schultz showed that one and the same substance, protoplasm, occurred in unicellular forms and in the higher plants and animals; that in plants this substance, though usually enclosed within a cell membrane, was sometimes naked (e.g. sperm spores), while in many animal tissues and in many of the unicellular forms the cell-membrane was always absent. He therefore concluded that in all cases the cell-membrane was unessential, and he defined the “cell” of Schleiden and Schwann as “a small mass of protoplasm endowed with the attributes of life” (1861). In the same year the physiologist Briicke, examining the cytoplasm of certain Bacteria, showed that the protoplasm was present only in a lattice-like network. This first introduced the hypothesis of the protoplasm itself, the nuclear membrane, and the “nuclear membrane” theory as it is called, subsequently to be developed into the more complex and universal theory of the cell. In the latter the protoplasm is more or less enclosed by a nuclear membrane, and the “nuclear membrane” is divided into two distinct portions, a clear fluid portion, the “protoplasm,” and a more or less opaque portion in the form of a coarser or finer “nuclear reticulum.” This latter is again composed of two parts, the “nucleolus,” and, embedded in the latter and often irregularly distributed, the “nucleoli.” The latter is usually more or less spherical, and has often been considered as a constant cell-structure. It is a minute granule, usually lying in the cytoplasm, and forms an important part in cell-division and fertilization (see below).

**Cytoplasmic continuity between the cells of the organism.** This continuity, which is effected by fine protoplasmic threads (“cell-bridges”) piercing the cell-wall and bridging the intercellular spaces when these are present, is to be regarded as the morphological expression of the physiological interdependence of the various—often widely separated—tissues of the body. It is probable that it is the specialization of this primitive condition which has produced the cell-elements of the nervous system. In many cases the cell-connections are so extensive as to obliterate cell-boundaries. A good example of such a “syncytial” tissue is provided by the heart muscle of Vertebrates and the intestinal musculature of Insects (Webber).

In all multicellular, and in the great majority of unicellular, organisms the protoplasm of the cell-unit is differentiated into two very distinct regions,—a more or less central region, the nucleus, and a peripheral region (usually much more extensive), the cell-body or cytoplasm. This universal morphological differentiation of the protoplasm is accompanied by corresponding chemical differences, and is the expression of a physiological division of labour of fundamental importance. In some of the simpler unicellular organisms, e.g. *Tetrahymena*, the differentiated protoplasm is not segregated. Such forms are said to have a “distributed” nucleus, and among the Protozoa correspond to Haeckel’s “Protista.” It is probable that among plants the Bacteria and Cyanophyceae have a similar distributed nucleus. In all these forms, however, the segregation is well marked, and a “nuclear membrane” separates the substance of the nucleus, or “karyoplasm,” from the surrounding “cytoplasm.” Within the nuclear membrane the karyoplasm is differentiated into two very distinct portions, a clear fluid portion, the “karyolymph,” and a firmer portion in the form of a coarser or finer “nuclear reticulum.” This latter is again composed of two parts, the “nucleolus,” and, embedded in the latter and often irregularly distributed, the “nucleoli.” The latter is usually more or less spherical, and has often been considered as a constant cell-structure. It is a minute granule, usually lying in the cytoplasm, and plays an important part in cell-division and fertilization (see below).

**Cell-differentiation.**—Both among unicellular and multicellular individuals the cell assumes the most varied forms and performs the most diverse functions. In all cases, however, whether we examine the free-living shapeless and slowly creeping *Amoeba*, or the striped muscle cell or spermatzoon of the Metazoa (fig. 1, b and c), the constant recurrence of cytoplasm and nucleus show that we have to deal in each case with a cell. The variation in the form and structure of the cell is an expression of that universal economic law of nature, “division of labour,” with its almost invariable accompanying “morphological differentiation”; the earliest and most fundamental example being in the differentiation of the cell-protoplasm into cytoplasm and nucleus. In multicellular individuals the division of labour to which the structural complexity of the organism is due is between the individual cell-units, some cells developing one

It is evident that the cytoplasmic continuity may have upon our conception of the organization a very great influence. The influence this protoplasmic continuity may have upon our conception of the organization is referred to below (Present Position of the Cell-theory).

*The Chromoplastids of the vegetable cell come under a different category of cell-inclusions; see PLANTS: Cytology.*

1. Cf. Pfeffer’s classical experiments on the physiological significance of cell-continuity in plant tissues (Über den Einfluss des Zellkernes auf die Bildung der Zellbast, 1896). The recent work in physiology and bacteriology by Hofmeister and circulating in the blood-stream exert upon other and widely different tissues, should not be lost sight of in this connexion.

2. The influence this protoplasmic continuity may have upon our conception of the organization is referred to below (Present Position of the Cell-theory).

3. A term (from καταρρήσις, kernel) suggested by Flemming to replace Strasburger’s hybrid term “nucleoplasm” (1882). The earlier workers, e.g. Leydig, Schultze, Brücke, de Bary, &c., restricted the term protoplasm to the cell-body—the “Cytoplasma” of Strasburger, an example still followed by O. Hertwig.

4. From ἰωμα, a thread, Schwarz, 1887.

5. From χρωμα, colour, Flemming, 1879.
CYTOLOGY

aspect, some another, of their vital attributes. Thus one cell specializes in, say, secretion, another in contractility, another in receiving and carrying stimuli, and so forth, so that we have the gland cell, the muscle cell, and the nerve cell, each appropriately grouped with its fellows to constitute the particular tissue or organ—gland, muscle or brain—which has for its function that of its constituent cells. In unicellular animals we also find division of labour and its accompanying morphological differentiation, but here there is no subdivision of the protoplasm of the organism into the semi-autonomous units which so greatly facilitate division of labour in the Metazoa; instead, division of labour must be between different regions of protoplasm in the single cell. The sharply defined character of this regional differentiation in the Protozoa, and the surprising structural complexity it may produce, sufficiently clearly show that although multicellular structure has greatly facilitated regional differentiation in the Metazoa, it is by no means essential to this process (see below, Present Position of the Cells).

It is not within the scope of this article to attempt a comprehensive review of the variety in structural complexity to which this division of labour among the cells of the Metazoa and the regional differentiation of the cell-bodies of the Protozoa has given rise. Some indication of the wealth of variety may be best given by taking a general survey of cell-modifications, grouped according to the cell-attributes the expression of which they facilitate.

(a) Structural Complexity facilitating Movement.—One of the most striking, and hence earliest described, of the fundamental attributes of protoplasm is its power of spontaneous movement. This is seen in the walled cell of plant tissue and in

the naked cell-body of Amoeba. In the latter case the streaming movements of the naked protoplasm are accompanied by the formation of "pseudopodia," and result in the highly characteristic "amoeboid" creeping movement of this and similar organisms (e.g. lymph corpuscles of the blood). In these examples the whole protoplasm participates in the movement, there has been no division of labour, and there is, therefore, no visible morphological differentiation. In many cells, movement (either of the entire body or of the surrounding medium) is by means of slender whip-like processes of the protoplasm flagella or cilia. These represent modified pseudopodia, and in the formation of the motile gametes of some of the lower forms, e.g. Myxomycetes (de Bary, 1859), Rhiizopods (R. Hertwig, 1874), &c., the actual conversion of a pseudopodium into a flagellum can be witnessed. These vibratile processes may be either one or few in number, and are then large in size and move independently of one another; or they may be very numerous, covering the free surface of the cell (fig. 2, a); they are then very small and move strictly in unison. In the former case they are termed "flagella," in the latter "cilia." In some cases the flagellum is accompanied by an undulating membrane (e.g. Trypanosomes among the protozoa and in many spermatozoa), and it may be situated either at the front end (Euglena) or hind end (spermatozoa) of the body during motion. The cilia may form a

uniform coating to the free surface of the cell, as in ciliated epithelium (fig. 2, a) and many infusoria, or the cilia may be variously modified and restricted to special regions of the body, e.g. the "undulating membrane" of the peristomial region in many infusoria, the swimming combs of the Ctenophora (q.v.).

**Fig. 2.**—Types of Cells. \(a\), Ciliated epithelial cells. (After Heidenhain.) \(b\), Mucous-secreting "goblet"-cells. (After Gurwitsch.)

and the flame cells of the Platycladus (q.v.). In one group of infusoria (Hypotricha), the cilia, "cirri," have attained a high degree of differentiation, and reach a considerable size. Both cilia and flagella spring directly from the cell-protoplasm, piercing the cell-membrane, when this is present. At the point where they become continuous with the cell-body there is usually a deeply staining "basal granule." In some cases the flagella are in direct connexion with the centrosome (see below, Cell-division), e.g. Trypanosoma and spermatozoa, in some cases even while the centrosome is functioning in mitosis (e.g. insect spermatogenesis, Henneuy and Meyers (fig. 3).

In the ability of Amoeba to contract into a spherical mass, and in the presence of its protoplasm of the contractile vacuole, we see another type of spontaneous movement—contractility — of the protoplasm. In the "musculo-epithelial" cells of Hydra,

**Fig. 3.**—Spermatoctyes of Bombyx mori, showing the precocious appearance of the spermatozoan flagellum and its relation to the centrosome. (After Henneuy.)

the elongated basal portion of the cell alone possesses this contractility. In the higher Metazoa the whole cell—muscle cell—is specialized for contractility, and shows, as a result of its specialization, a distinct fibrillation. This fibrillation is foreshadowed in the contractile regions of many Protozoa, e.g.

1 The formation of pseudopodia and accompanying changes in form of Amoeba were observed as early as 1755 by Raeesel von Rosenholz, who named it on this account the "little Proteus."
in the cirri of hypotrichous Infusoria, the tentacle of Nautilus, and the metachronal layer of Gregarines. In the quickly contracting muscle cell of Vertebrates and insects, further specialization has produced a structure of considerable complexity (fig. 1, b). Here also the cell is fibillated, but the fibriilae (sarcostyles) are much more distinct, and are segmented in a manner which gives to the entire cell a "cross striated" appearance. Since quick movement is usually (but not always) associated with voluntary control, these striated muscle cells are often termed "voluntary" muscle fibres. The great increase in length of these cells is accompanied by the fragmentation of the originally single nucleus.

(b) Cell-modification in Relation to Secretion.—Just as the complex movements considered above were the result of a great development of the power of spontaneous movement possessed by all protoplasm, so cell-secretion is the result of a development of the metabolic processes underlying all vital phenomena. But whereas specialization of the protoplasm for movement resulted in a very obvious morphological complexity, specialization for secretion results in molecular complexity, and only rarely and indirectly results in morphological differentiation. Usually indeed the specialization is only rendered evident by the appearance of the formed secretion, e.g. mucus-secreting epithelial cells (fig. 2, b), the ovarian ovum and the fat cell (fig. 1, a). In some cases a distinct fibillation of the cytoplasm accompanies or precedes the appearance of the cell-secretion (Mathews, pancreas cell of Amphibia). In many cases the internal secretion is no mere accumulation, e.g. the internal skeleton of the Radiolaria, and the nematocysts of the Coelentera. Frequently in animal tissues the cell-secretions are accumulated in the intercellular spaces, and result in the formation of the various "connective tissues," all of which are characterized by the immense amount of intercellular substance, e.g. fibrous tissue, cartilage and bone. Cell-modifications facilitating the general metabolism, but not necessarily indicating specialized secretion, also occur, e.g. the "gullet" of many Protozoa, the suctorial tubules of the Acinetaria, and the "nutritive processes" of the ovarian ova in many Lepidoptera. Mention may be made here of the network or canal system of the cytoplasm, described for many cells by Golgi, Holgren and others. An enigmatical structure, the "yolk-nucleus" of many ova, has been frequently regarded as a structure of considerable metabolic importance, e.g. Bambeke (1868) for Pholcus.¹

Striking modifications resulting from specialization in secretion are frequently presented by the nucleus. In many secreting

Origin of Cells.—In the preceding sections we have considered the structure of the cell in relation to the fundamental attributes of cell-metabolism, irritability, and movement. We have now

---

2 Claude Bernard expressed the same conclusion in 1888. Rejecting both the view that vital phenomena were identical with chemico-physical phenomena, and that which regarded them as totally distinct, he suggested a third point of view: "l'étellemut ultime d'abnomène est physique; l'arrangement est vital."

3 Many forms of response to stimuli involve no visible specialization, e.g. positive and negative heliotropism, chemiotropism, geotropism, &c., seen more especially in plants, but occurring also in the animal kingdom.
to consider the cell in relation to yet another vital attribute, that of reproduction. Just as we now know that the phenomena of assimilation, respiration, excretion, response, movement and so forth, characteristic of living things, are but the co-ordinated expressions of the corresponding activities of the constituent cells, so we now know that the reproduction of the organism is, in its ultimate analysis, a cell-process. Our knowledge of the essential fact that cells only arise by the division of pre-existing cells, now a fundamental axiom of biology, and of the details of this process, have been acquired during recent years by the strenuous efforts of numerous workers. Matthias Jakob Schleiden (1838) supposed that in plants the new cell arose from the parental cell by a sort of "crystallizing" process from the cell fluid or "cytoblastema"; the nucleoli appearing first, then the nucleus, and finally the cell-body. Theodor Schwann (1839) extended Schleiden's theory to animal tissues, with this yet greater error, that new cells might arise, not only within the mother cell as Schleiden had supposed, but also in the intercellular substance so common in animal tissues (to which he also gave the term "cytoblastema"). By 1846, however, the botanists, thanks mainly to the efforts of Hugo von Mohl and Nägeli, recognized as a general law that cells only arise by the division of a pre-existing cell. But it was long before the universal application of this law was recognized by zoologists; the delay being largely due to pathological phenomena. Prominent among these are: Schleiden (1873), Fol (1873-1877), Auerbach (1874), Bütschli (1876), Strasburger (1875-1888), O. Hertwig (1875-1890), R. Hertwig (1875-1879), Flemming (1879-1891), van Beneden (1883-1897), Rabl (1889), Boveri (1887-1905), Retzius (1887), and many others, that we begin to gain an insight into the process. In 1882 W. Flemming was able to extend Virchow's aphorism to the nucleus also: *omnis nucleus e nucleo.

**Outline of Cell-division.**—There are two very distinct methods of cell-division. The more general and also more complicated method is accompanied by the formation of a complex fibrillar mechanism, and was on this account termed "mitosis" (pl. *mitos*, a thread) by W. Flemming (1882), and "karyokinesis" (Gr. *karyon*, nut; *kinesis*, change, movement) by W. Schleicher (1878). The other method, "amitosis," or direct division, is unaccompanied by any visible mechanism and is of relatively exceptional occurrence. In the more usual method of cell-division, or "mitosis," we can distinguish two distinct but parallel processes, the one undergone by the chromatin and resulting in the "chromatic figure," the other usually only concerning the cytoplasm and resulting in the "achromatic figure."

We will consider the chromatin changes first. The chromatin granules lose their scattered arrangement on the nuclear reticulum, and become instead arranged in a linear series to form a coiled and deeply staining "spireme thread" (fig. 6, a). As the thread contracts, its granular origin becomes less evident, and at the same time the coils become fewer in number; the "close" spireme of earlier stages becomes the "loose" spireme of later stages. As the spireme thread contracts, it segments into a number of short, and usually U-shaped, segments—the "chromosomes" (Waldeyer, 1888). The number of these chromosomes is always constant for the cells of any given species of plant or animal, but varies greatly in number in different species. Thus in the parasitic worm *Ascaris meglolopha*, var. *univalens*, there are only two. In the crustacean *Artemia* Bauer found 168, while in the amphibian *Salamandra maculata*, as also in the lily, the number is 24. While these changes have been proceeding in the nucleus, changes in the cytoplasm have resulted in the formation of the achromatic figure. These cytoplasmic changes are initiated by the division into two of a minute body, the "centrosome," originally discovered by P. J. van Beneden in 1883, and usually lying not far from the nucleus (fig. 6, a). The daughter centrosomes separate from one another, travelling to opposite poles of the nucleus. At the same time radiations extend out into the cytoplasm from the centrosomes, and, as the nuclear membrane disappears, invade the nuclear area (fig. 7, a). Some of the fibrillae in the latter region become attached to the chromosomes and are termed "mantle fibres"; others become continuous from one centrosome to the other and constitute the "spindle fibres." The remaining radiations at the two poles of the spindle are the "astral rays." (The details of the formation of the achromatic figure vary considerably, some indication of this is given in the next section in connexion with the question of the origin of the mitotic mechanism.) The chromosomes now arrange themselves in the "equatorial plate" of the spindle and each splits longitudinally into two (fig. 6, b and c). The sister chromosomes now pass to opposite poles of the spindle (fig. 6, d), and there, returning to the "resting" condition, constitute the daughter nuclei. Division of the cell follows, usually, in animals, by simple constriction. Both Theodor Boveri and van Beneden, in their papers of 1887, regarded the centrosome as initiating, not only the division of the cell-body but that of the chromatin also; Beneden even suggested that the pull of the mantle fibres caused the division of the chromatin in the equatorial plate. W. Pfiztnzer in 1882 was the first to show that the splitting of the chromosomes in the equatorial plate was only the reappearance of a split in the spireme thread and was due to a corresponding

---

4 Prominent among these are: Schleiden (1873), Fol (1873-1877), Auerbach (1874), Bütschli (1876), Strasburger (1875-1888), O. Hertwig (1875-1890), R. Hertwig (1875-1879), Flemming (1879-1891), van Beneden (1883-1897), Rabl (1889), Boveri (1887-1905).

5 This distinction between the chromatic and achromatic portions of the mitotic figure is due to Flemming.

6 The genesis of the spireme thread was first described by E. G. Balbiani in 1876.
division into two of each of the chromatin granules. In the spermatogenic cells of *Ascaris*, A. Brauer has shown that the chromatin granules divide while still scattered over the nuclear reticulum and before either the formation of a spine thread or the division of the centrosome. In many other cases the reverse of this condition occurs, the centrosome dividing long before there is any indication of division in the nucleus (e.g. salamander spermatogenic cells, Meves, &c.). We must therefore, with Boveri and Brauer, regard the division of the chromatin in mitosis as a distinct reproductive act on the part of the chromatin granules, the chromosomes being merely aggregates (temporary or permanent, *vide infra*) of these self-propagating units.

For convenience of description it is usual to recognize four periods in mitosis: (I.) Prophase, (II.) Metaphase, (III.) Anaphase, and (IV.) Telophase (Strasburger, 1884). The prophase covers all changes up to the completion of the mitotic figure. The metaphase is the parting of the center chromosomes in the equatorial plate; their passage to opposite poles of the spindle constitutes the anaphase; and their reconstruction to form the resting daughter nuclei, the telophase.

The Achromatic Figure.—The mode of origin of the achromatic figure varies greatly. In some cases a distinct and continuous spindle, the "central spindle" of F. Hermann, is visible from the very first separation of the daughter centrosomes (e.g. salamander spermatogenic cell)\(^1\) (fig. 7, b). In other cases the rays only invade the nuclear area and become continuous in the equatorial plane after the centrosomes have assumed their definitive positions at the two poles of the nucleus, and may even appear to indent the disappearing nuclear membrane as they invade the nuclear area.\(^2\) In the salamander testis cell (fig. 7, b), and in many other cases, the whole of the achromatic figure is obviously of cytoplasmic origin. In many cases, however, it equally obviously arises within the nucleus,\(^3\) while in yet other cases\(^4\) the spindle fibres are of mixed origin. The question, therefore, of the cytoplasmic or nuclear origin of the achromatic figure, at one time regarded as of considerable importance, is wholly immaterial. Various elaborate theories have been propounded to explain the mechanism of the mitotic figure. H. Foi (1873) regarded the centrosomes as centres of attractive forces, and compared the mitotic figure to the lines of force in the magnetic field, a comparison made by numerous subsequent workers. E. Klein's hypotheses of two opposing systems of contractile fibrillae, elaborated by van Beneden (1883, 1887) and accepted by Boveri (1888), was still further extended by R. Heidenhain in relation to the leucocytes of the salamander, in which there is a permanent centrosome and astral rays to which the contractile movements of the cell appear to be due\(^6\) (fig. 7, a). Hermann on the other hand confined the contractility to the astral and mantle fibres; while L. Druner regarded the spindle as exerting a pushing force, for not only do the interzonal spindle fibres elongate during the anaphase, but they were often at this period contorted, while on the other hand astral rays may be entirely absent (e.g. *Infusoria*), and in some cases the spindle pole may be caused to project at the surface of the cell. The facility of these attempted mechanical explanations of mitosis is sufficiently clearly shown, not only by the contradictory nature of the explanations themselves, but by the fact that, in amitosis, nuclear and cytoplasmic division occur without any fibrillar mechanism whatever.

**Centrosome.**—This minute body was first detected at the spindle poles by Flemming in 1875, and independently by P. J. van Beneden in 1876. The important part played by the centrosome in fertilization,\(^7\) first described by van Beneden and Theodor Boveri in their papers of 1887–1888, together with the behaviour of this structure in mitosis, led these authors to regard the centrosome not only as the dynamic centre of the cell but as a permanent cell-organ, which, like the nucleus, passed by division from one cell-generation to the next. This conclusion appeared to receive considerable support from the recognition of the centrosome in various kinds of resting cells,\(^8\) and especially from the relation this structure frequently shows to the locomotor apparatus of the cell (e.g. its position in the centre of the radiating fibrillae in the contractile lymph and pigment cells, and its relation to the vibratile flagellum in spermatozoa and some protozoa, e.g. Trypanosoma).\(^9\) In almost all cases the centrosome of the resting cell, when this can be detected, lies in the cytoplasm, and is often already divided in preparation for the next mitotic division (e.g. spermatogenic cells of the salamander; Meves). In some cases, however, it resides in, or arises from, the nucleus (Brauer; spermatogenesis of *Ascaris*, var. *univulens*). This indifferent nuclear or cytoplasmic position for the centrosome is paralleled by the attraction sphere or homologue of the centrosome in many Protozoa. Thus in many forms, e.g. *Euglena* (Keutel), it lies within the nucleus, while in other forms, e.g. *Notoctata* (Ishikawa, 1894, 1898; Calkins, 1898) and *Paramoeba* (F. Schaudinn, 1896), it lies in the cytoplasm, while in *Tetramitus* it coexists with a "distributed" nucleus. In the Heliozoa conditions are exceptionally interesting; not only is the centrosome—here resembling in appearance that of the higher forms—permanently visible and extranuclear, lying at the centre of the radiations characteristic of these forms, but there is the strongest possible evidence for its formation *de novo*. For Schaudinn has shown in *Acintochytris* that, in the formation of the swarm spores, the nucleus divides amitotically, the centrosome remaining visible and unchanged at the centre of the radiating processes. Yet a centrosome appears later in the nucleus of the swarm spores and migrates into the cytoplasm. The experiments of T. H. Morgan and E. B. Wilson, in which numerous centrosomes and asters ("cystasters") are caused to appear in unfertilized sea-urchin eggs by a brief immersion in a 15% solution of magnesium

---

\(^1\) The discovery by Hermann of the central spindle first clearly showed that two kinds of fibres must be recognized in the mitotic figure. Those of the central spindle correspond to the continuous spindle fibres of Flemming (1891) and Strasburger (1884), and the mantle fibres, i.e. half-spindle or *Polstrahlen*, of van Beneden (1887) and Boveri (1889–1890).

\(^2\) Planter, Wataše, Grienen, and others.

\(^3\) E.g. *Englypha* (Scheuwaloff, 1888). Infusoria (R. Hertwig, 1898) also show a centrosphere for *Ophryotricha*, and many other cases.

\(^4\) E.g. Bauer, spermatogenic cells of *Ascaris* univulens.

\(^5\) Cf. also Wataše, Solger, and Zimmermann.

\(^6\) This term is due to Boveri (Zellstudien, ii., 1888, p. 68; Jen. Zeit., xxiii.), but it was introduced by him to include the region of modified cytoplasm or "centrosphere." often enclosing the centrosome proper, i.e., "centriole" of Boveri.

\(^7\) For outline of fertilization see article REPRODUCTION.

\(^8\) E.g. lymph and various epithelial and connective tissue cells of salamander larva (Flemming, 1891; Heidenhain, 1892); pigment cells of fishes (Solger, 1891); red blood corpuscles (Heidenhain, 1898); and numerous others.

\(^9\) For an interesting development of this subject see Wataše (1894). This author not only identifies the centrosome with the structures seen in lymph cells, &c., but compares it to the basal granules of ciliated cells and to the varicoses swellings on the sarcocysts of striped muscle cells.
chloride in sea-water, as also the possibility in many cases that even in normal fertilization the cleavage centrosomes may arise de novo, make it no longer possible to regard the centrosome as a permanent centre of the chromosomes.

Significance of Mitosis.—Whatever may be the nature of the chemical-physical changes occurring during cell-division, of which the achromatic spindle and astral rays are the visible expression, it is certain that the whole of this complicated process has for its function, not the division of the chromatin, for that has already occurred on the spireme thread or even earlier, but the distribution of the divided chromatin granules to the two daughter nuclei. It is indeed usually assumed that the mitotic mechanism is not merely for the distribution, but for the equal distribution, of the sister granules to each daughter nucleus. The conspicuous part the chromatin is seen to play in the whole mechanism of heredity—in maturation, fertilization and development—indicating as it does that the chromatin is the chief, if not the only, bearer of the specific qualities of the organism, sufficiently clearly emphasizes the importance of the equal distribution of this substance between the daughter cells at successive cell-divisions. There are, however, some essential reservations to the interpretation of mitosis as an adaptation to ensure this equal distribution of the chromatin. Not only does the occurrence of amitosis show that the mitotic mechanism is not essential for either nuclear or cytoplasmic division, but direct division may occur in the life-history of the germ cells, the very point at which it should not occur had mitosis the significance usually attached to it. On the other hand, the most elaborate mitosis occurs in cell-tissues (e.g. skin of salamander larva) which can take no possible share in the reproduction of the species. Moreover, we have no reason for supposing that the division of the chromatin in amitosis is not as meristic, and its subsequent distribution as equal, as is visibly the case in mitosis. It is necessary, therefore, to seek for some other explanation of the elaborate mechanism of mitosis than that which assumes it necessary for the equal distribution of the divided chromatin granules. The present writer believes the true explanation to be found in that great economical law of nature, "division of labour." The same economy which, working under the control of natural selection, has produced the complexly differentiated tissues of the higher metazoa, which has led to the sexual differentiation between the conjugating gametes and thus to the sexual differentiation of the parents, has resulted in the production of mitosis. Only here the economy finds expression in division of labour, not in space, but in time. The work of the self-propagating chromatin granules is so ordered that periods of undisturbed metabolic activity alternate with periods of reproductive activity. The brief space of time occupied by the latter process has necessitated a more elaborate specialization of the forces—whatever their nature—controlling cell-division; a specialization which has resulted, just as a similar specialization in so many other cases has resulted, in a visible differentiation of the cell-protoplasm. This explanation is in harmony with the occurrence of typical mitosis in active tissue cells on the one hand, and of amitosis in the relatively quiescent primary germ cells on the other.

The most striking feature in the behaviour of the chromatin in mitosis is its resolution, at each division, into a—for any particular species—constant number of chromosomes. This constant recurrence of the specific number of chromosomes at every cell-division is capable of explanation in two radically different ways. One explanation assumes for the organism a specific peculiarity determining the segmentation of the spireme thread into a definite number of segments (Delage, 1899 and 1901). The other regards chromosomes as independent units of the cell, retaining their identity between successive cell-divisions. The latter "Individualitäts Hypothese" was originally put forward by Theodor Boveri in 1887 as a result of C. Rabl's observation (1885) that in epidermal cells of the salamander larva the chromosomes reappear in the mitosis of the daughter cells with the same arrangement as they possessed in the prophase of the mother cell—the angles of the U-shaped chromosomes being all directed towards one pole (Rabl's "Poleite") of the nucleus. In the formation of the "resting" nucleus, the chromatin, becoming metabolically active, flows out on to the linin reticulum, all trace of the chromosomes being for the time lost. In Ascaris, Boveri (1888) observed similar but still more striking results. The thickened ends of the four elongated chromosomes cause projections on the nuclear surface throughout the resting period, and the ends of the reappearing chromosomes always coincided with these projections; cf. also Sutton (1900) on locust spermatogonia. Moreover, the arrangement of the chromosomes must follow one of three well-marked groupings, and this is determined for each individual in the cleavage spindle of the egg and maintained throughout later development (fig. 8).

In the same worm (var. univalens) Boveri (1888 and 1909) found that occasional abnormalities in maturation resulted in the suppression of the first polar body and the inclusion of its chromosomes in the second maturation spindle; the egg-nucleus at the time of fertilization thus having two chromosomes instead of one, while the spermatozoon nucleus has only one. Three chromosomes instead of two reappear in subsequent divisions. Boveri's "Individualitäts Hypothese" received striking support from the work of Herla (1893), L. R. Zoj (1895) and O. zur Strassen (1898). Herla and Zoj showed that if the egg of Ascaris megaloecephala (var. binale) possesses two chromosomes, be fertilized with the spermatozoon of var. univalens, in which the germ cell has only one chromosome and that smaller than either of the two in the other variety, three chromosomes reappear, two large and one small, in the cleavage divisions of the resulting hybrid embryo. Zur Strassen's observations on the giant embryos of Ascaris also support Boveri's theory. These embryos arise by the fusion of eggs, either before or after fertilization. The number of chromosomes in the subsequent cleavage-figures is proportional to the number of nuclei that have fused together. Similar results are given by Boveri's (1893-1895) and T. H. Morgan's (1905) experiments on the fertilization of enucleated sea-urchin egg-fragments; all the nuclei of the resulting embryo having only half the number of chromosomes characteristic of the species (e.g. in Echinus 9 instead of 18).

All the facts point to the conclusion that, as Boveri expressed it in his Grundzüge der Zahlenkonstanz (1888), "the number of chromosomes arising from a resting nucleus is solely dependent on the number which originally entered into its composition."

It should, however, be noted that the assumption that a particular group of characters remains always associated in a particular chromosome is one that is very difficult to reconcile with the mode of inheritance of Mendelian pairs of characters in the case of organisms with a relatively small chromosome number.
Boveri's Law of Proportional Nuclear Growth.—The chromatin in the nucleus is exactly halved at every cell-division. As the bulk of the chromatin remains constant from one cell-generation to another, it must double its bulk between successive divisions. That this proportional growth of the chromatin is dependent solely on the chromatin mass, and not on that of the cell, is very clearly indicated by cases where the normal chromatin mass has been artificially increased or reduced, the chromatin in either case doubling its bulk between successive cell-divisions, and neither the mass of the chromatin nor the number of the chromosomes undergoing any readjustment. By double or partial fertilization, different regions in the same embryo may show nuclei of different sizes (Boveri). We must therefore distinguish in the cell between "young" and "adult" chromatin. In other words the chromatin must be regarded as being composed of individual units, each with a definite constant structure and maximum growth (Boveri, 1904). This conclusion is strongly suggested, not only by the evidence in favour of the individuality of the chromosomes considered above, but also by the independent reproductive activity of the chromatin granules in the prophase of mitosis.

Differenzierung am chromosomen. If we grant the assumption of a persistent individuality for the chromosomes, then it becomes possible to consider whether in one and the same nucleus these structures may not take varying parts in controlling the cell's activity in development and in inheritance. Such a differentiation among the chromosomes would be due to independent ancestry rather than to the economy resulting from a division of labour; nevertheless a division of labour of a sort would be the result of this gradual divergence of the chromosomes from one another, and we might therefore expect that, in some cases at least, a morphological would accompany the physiological differentiation. Examples of such a morphological differentiation do indeed occur in the "accessory" chromosomes first described by H. Henking (1891) for the spermatogonia of *Pyrrhocoris*, and since described for numerous other insects, follows that the latter need always, or even generally, be accompanied by the former. Since, however, the specific characters of the organism must be due to the combined activity of all the chromosomes, any physiological differentiation among the latter should result in abnormal development if the full complement of chromosomes be not present. Boveri, utilizing Herbst's method for separating echinoderm blastomeres, has interpreted in this manner the abnormal development which H. Driesch found almost invariably to follow the double fertilisation of the sea-urchin egg. In such eggs the first cleavage spindles is four-poled. The chromosomes are half again as numerous as in normally fertilized eggs (54 instead of 36), but each is only divided once, so that in the distribution of the resulting 108 chromosomes the four daughter nuclei receive each only 27 instead of 36 (assuming the distribution to be fairly equal, which is by no means usually the case in four-poled mitosis). Driesch had already (1900) shown that any one of the first four blastomeres of a normally fertilized egg will, if isolated, develop normally. Boveri found that in the case of the doubly fertilized egg the isolated "3" blastomeres develop very variously, a variety only of their number of chromosomes varying chromosome equipment. Occasionally a three-poled instead of a four-poled figure resulted from double fertilization. In such cases Driesch found, as we should expect from Boveri's interpretation, that the percentage of approximately normal larvae was considerably greater; for not only would the chances of an equal distribution of the chromosomes be much greater, but the number received by each of the three daughter cells would approximate to, or even equal, the normal.

Reduction.—In all the Metazoa the prevailing, and in the higher forms the only, method of reproduction is by the union (conjugation) of two "sexually" differentiated germ-cells or "gametes"; a small motile "microgamete" or spermatozoon and a large yolk-laden "macrogamete" or ovum (see Reproduction). This differentiation between the germ-cells is another example of the advantages of division of labour; for while the onus of bringing about the union of the germ-cells is thrown entirely on the spermatozoon, the egg devotes itself to the accumulation of food-material (yolk) for the subsequent use of the developing embryo. Far more yolk is thus secreted that would be possible by the combined efforts of both the germ-cells had each of these at the same time to preserve its motility. The fundamental physiological difference which this division of labour has produced in the germ-cells is reflected on the general metabolism of the parents and underlies the sexual differentiation of the latter. Beyond this, however, sexual differentiation does not go. The two germ nuclei which enter into the formation of the first mitotic figure of the developing egg are not only physiologically equivalent, but, at the time of their union in the egg, are usually morphologically identical. The essence of fertilization is, therefore, the union of two germ nuclei only differing from one another in that they are derived from separate individuals. Since the number of chromosomes appearing in mitosis is solely dependent on the number which each nucleus contains, each containing a duplicate set of chromosomes, one of maternal and the other of paternal origin, the two sets alone suffices for development. This is clearly shown by the experiments of Loeb (1899) and Wilson (1901) on the artificial parthenogenesis of the sea-urchin egg; and of O. Hertwig (1889) and Scholl (1899) on the fertilization of enucleated Echinoderm eggs (Merogony, Delage). The fact that in some forms, e.g. *Ascaris megalocephala* var. *univalens*, only one chromosome is derived from each parent, originally led Boveri to conclude that only chromosomes must necessarily be physiologically equivalent.

From Boveri's (1891) *Uber mehrzeitige Zelldifferenzierung und ihre Bedeutung für die Herkunft der Geschlechtszellen, by permission of Gustav Fischer.*

Fig. 9.—Preparation for Mitosis. a, Spermatogonium of *Brachystola magna* with resting nucleus; b, Same with phase for mitosis. (After Sutton.)

Arachnids and Myriapods. W. Sutton's work on the spermatogenesis of *Brachyplectena magna* is of especial interest in this connexion. Not only does the "accessory chromosome" in this insect form a resting nucleus independent, and obviously physiologically differentiated from that formed from the remaining chromosomes (fig. 9, a), but the latter are themselves differentiated by size, there being one pair of chromosomes of each size (fig. 9, b), a point of considerable interest when we remember that half the chromosomes in each cell are necessarily derived from each parent.

Although this morphological differentiation among the chromosomes is undoubtedly to be regarded as indicating a corresponding physiological differentiation, it by no means

1 Boveri (1902), "Fertilization of enucleated *Echinus*-egg fragments," and M. Boveri (1903), by shaking the egg shortly after fertilization the sperm centrosome is prevented from dividing, and a monster instead of a diaster results, the divided chromosomes remaining in the one nucleus.

2 Cf. especially in this connexion Häcker's paper *Über die Schicksale der tierischen und pflanzlichen Kernelemente* (1902).

3 Boveri's *Über mehrzeitige Zelldifferenzierung und ihre Bedeutung für die Herkunft der Geschlechtszellen* (1891).

The equivalence of the germ nuclei in development is shown by the experiments on the fertilization of enucleated eggs and artificial parthenogenesis already referred to.

7 O. Hertwig, 1873; but esp. van Beneden, 1883.
originally entered into the composition of the nucleus (Boveri's Law of Chromosome-Constancy), it follows that, in the mitotic figures of the developing embryo, the chromosomes will be half maternal, half paternal in origin; the germ nuclei thus necessarily possessing only half the number of chromosomes characteristic of the ordinary tissue cells of species, i.e., the somatic number. The manner in which this "reduction" is brought about, and the significance to be attached to the process, constitute the most hotly debated questions in cytology. In all the metazoa the phenomenon of reduction is associated with the two last and, usually, rapidly succeeding "maturation" divisions by which the definitive germ-cells—ova or spermatozoa—are produced. Assuming the persistent individuality of the chromosomes, then there are only three conceivable methods by which this numerical reduction can be brought about (Boveri, 1904, p. 60).

(1) One-half the chromosomes degenerate. (2) The chromosomes are distributed entire, half to one daughter cell, half to the other (reducing division of Weismann, 1887). (3) The chromosomes fuse in pairs (Conjugation of the Chromosomes, Boveri, 1893). The first possibility—that of an actual degeneration of a part of the chromatin originally suggested by van Beneden and adopted by August Weismann, Boveri and others, has been long abandoned, and a steadily increasing bulk of evidence is tending to prove the general, if not universal, occurrence of the second method—the distribution between the daughter cells of undivided chromosomes. The occurrence of such a "reduction division" was postulated on theoretical grounds by Weismann (1887) and by Boveri (1888); by the former as a result of his adoption of de Vries' hypothesis of self-propagating and qualitatively varying units for the chromatin; by the latter in relation to his theory of chromosome individuality. The actual occurrence of this reducing division was first demonstrated by Henking (1891) for Pyrrhocoris, and afterwards by Hacker, vom Rath and many others, but especially by Ruckert (1894) for Cyclops (fig. 10). In this latter type the chromatin of the oocyte, as this prepares for the first maturation division, resolves itself into the usual number of 24 longitudinally arranged chromosomes (fig. 10, a). As these continue to thicken and contract a transverse fusion appears (fig. 10, c). This is to be regarded as a belated segmentation of the sperm thread, and shows that the reduction so far is only a "pseudo-reduction" (Rückert), the chromosomes being really all present but temporarily united in pairs, i.e., "bivalent" (Häcker). A striking confirmation of this interpretation is provided by Korschelt's description of reduction in the annelid Ophryotrocha. In this type the full somatic number of split chromosomes (here only four) appears, and these secondarily associate end to end in pairs, thus forming split "diads" (i.e. tetrads), in every way similar to those described by Ruckert for Cyclops. In the latter type, at the first maturation division, the sister diads are separated from one another, an "equating" division thus taking place. At the second division the diads are resolved into their constituent parts, and the "universal" chromosomes are distributed to the daughter cells (reducing division). A similar process has since been described for numerous other types (e.g. various arthropods, Haecker, 1893-1898; vom Rath, 1895; and by Sutton for Brachystola, 1902-1903). In Ophryotrocha, as in Pyrrhocoris (Henking), Anasa (Paulmeir), Peripatus (Montgomery), &c.,

![Cytology Diagram](https://example.com/cytology-diagram.png)

**Fig. 10.—Maturation Divisions.** a–d, Formation of the tetrads in Cyclops. (After Rückert.) e, 1st maturation division; separation of the bivalent sister chromosomes. f, 2nd maturation division; distribution of the univalent chromosomes.

The reduction occurs at the first maturation division ("pre-reduction") of Korschelt and Heider, 1900), instead of at the second division (post-reduction) as in most Copepods and Orthoptera. In many cases the tetrads (i.e. split chromosomes associated in pairs) have the form of rings, the genesis of which was first clearly determined by vom Rath (1892) in the mole cricket Gryllotalpa (fig. 11). In this form the sister diads remain united by their ends but widely separate in the middle (fig. 11, b). As in Cyclops, the belated transverse segmentation appears as the condensation of the chromatin proceeds (fig. 11, d), but the symmetrical tetrads which this process here produces make it impossible to determine at which of the two divisions reduction is effected. An essentially similar ring formation occurs in

---

2 First discovered by van Beneden (1883, 1887) for the egg of Ascaris.

3 In the case of the egg the whole of the yolk stored by the "oocyte" (cell-generation immediately preceding the maturation division) is handed on to only one of the four resulting cells—an obvious economy. The three yolkless cells are necessarily functionless—abortive ova—and are known as the "polar bodies" (Hertwig). In spermatogenesis the maturation divisions, though bearing the same relation to reduction (Plattner in oogonia), of Hertwig, 1899), give rise to four functional germ-cells. The explanation of the sexual differentiation given above, and that of polar body formation given here, render it needless to do more than mention the theories of Mimos (1877), van Beneden (1883) and others, by which "maturity" was regarded as removing the "male" element from the otherwise "hermaphrodite" egg.

4 Weismann postulated a transverse division of the chromosomes, not a distribution of entire chromosomes; but the result as far as the reduction in the number of hereditary qualities goes is the same. The inability of the mitotic mechanism to effect the transverse division of unsplit chromosomes is pointed out by Boveri (1904).
Enchaea and Calonous (vom Rath), and in the Copepods Heterocope and Diaptomus (Rücker), and in other types.

All the above cases, in which the reduction is effected by the distribution of entire chromosomes at one or other of the maturation divisions, may be grouped together as “pseudomitotic” (Häcker, and Korschelt & Heider). In sharp contrast to the pseudomitotic method is the “Eumitotic” method, in which the chromosomes are longitudinally divided at both divisions. Such a method not only robs the process of any “reducing” value in Weismann’s sense, but is in serious conflict with the chromosome-individuality hypothesis. Nevertheless it is in this sense that Boveri (1881) and van Beneden (1883–1887) described the maturation of the egg, and at a later period Brauer (1893) that of the spermatozoon, in Ascaris. In each case the tetrads are formed by the double longitudinal splitting of the chromosomes, the latter appearing in the prophase in the reduced number. Not only was the eumitotic method of Ascaris the first method to be described, but the descriptions are fully equal in point of clearness to that of Hertwig for the pseudomitotic maturation of Cyclops. A similar eumitotic maturation has been described for other types also, e.g. Sagitta and the Heteropods, but nowhere more frequently than in the Vertebrates among animals and the Phanerogams among plants. In these two latter groups the chromosomes of the reducing division only rarely have a ring form comparable to that seen in Gryllotalpa, &c. When such rings do occur their genesis is very obscure, and at no time do they present the appearance of “tetrad” division. It is the characteristic appearance these looped chromosomes give to the first maturation division in many Vertebrates, and especially in the Amphibia (fig. 12), that originally led Flemming (1887) to term this type of mitosis “heterotypical”.

“heterotypical”; the second division, lacking this peculiar appearance, being distinguished as “homotypical.” Until quite recently these looped chromosomes of the heterotypic mitosis of Vertebrates (and plants) were described as arising by the opening out of longitudinally split chromosomes, exactly as this occurs in the early prophase of the maturation divisions in such types as Gryllotalpa, Diaptomus, &c. In the heterotype mitosis, however, no transverse segmentation appears, and the halves of the rings, as they separate in the first division, show an obvious longitudinal split in preparation for the second division. Both divisions were thus interpreted as equating divisions.

The more recent works of Farmer and Moore (1903–1905), Montgomery (1903, Amphibia), and (for plants) Strasburger (1903–1904) have, however, that even for the higher plants and animals, a reducing division in Weismann’s sense occurs in an essentially similar manner to that so convincingly described by Rücker, vom Rath and others, for Invertebrates.

The homotypical method of maturation in Ascaris also has been maintained by O. Hertwig (1890), p. 277, Carnoy and Boveri (1904).

Nevertheless the possibility of a pseudomitotic interpretation of maturation in Ascaris also has been maintained by O. Hertwig (1890), p. 277, Carnoy and Boveri (1904).

The partial or even complete reconstruction of the nucleus between the heterotype and homotype division in Vertebrates makes it difficult to determine the identity of the split seen in the anaphase of the heterotype with that reappearing in the prophase of the homotype.

The whole process, in which the chromosome-individuality hypothesis is checked, is therefore incapable of undergoing reproductive fission in two successive mitotic divisions when these are not separated by a resting (i.e. growth) period. In addition to this, the “bipolar” condition of the adult chromosomes, which determines its mode of attachment to the spindle fibres from both poles of the spindle, is not possessed by the unripe chromatin. The undivided, i.e. unripe, chromosomes are therefore incapable of utilizing the mitotic mechanism for such a transverse fission as Weismann originally postulated. The difficulty is, however, at once overcome if the unripe chromosomes are associated in pairs in the equatorial plate, for the bivalent chromosomes so produced are bipolar just as are the chromosomes of the ordinary (i.e. “normal”) chromatin.

Invertebrates types. For the chromosomes of the heterotype mitosis arise by the looping round, not opening out, of the constituent chromosomes. The first division is thus a reducing division, while the second appearing in anaphase of the heterotype and presumably reappearing in the prophase of the homotype is the original split of the sperm thread.

The widespread, if not universal, formation of tetrads, i.e. the temporary union in pairs of split chromosomes, in reduction, and the relation this latter process always bears to two rapidly succeeding maturation divisions—those completing the gametogenic cycle in animals and terminating the sporophytic generation in plants,—has received a suggestive explanation at the hands of Boveri (1904). The growth of the chromatin is an indispensable prelude to its reproduction (Boveri’s Law of Proportional Growth). The chromatin is therefore incapable of undergoing reproductive fission in two successive mitotic divisions when these are not separated by a resting (i.e. growth) period. In addition to this, the “bipolar” condition of the adult chromosomes, which determines its mode of attachment to the spindle fibres from both poles of the spindle, is not possessed by the unripe chromatin. The undivided, i.e. unripe, chromosomes are therefore incapable of utilizing the mitotic mechanism for such a transverse fission as Weismann originally postulated. The difficulty is, however, at once overcome if the unripe chromosomes are associated in pairs in the equatorial plate, for the bivalent chromosomes so produced are bipolar just as are the chromosomes of the ordinary (i.e. “normal”) chromatin.

Synapsis (συνάψευπ, to fuse together).—During the prophase of the reducing or heterotype divisions the whole of the chromatin becomes temporarily massed together at one pole of the nucleus (Moore, 1896, for Elasmobranchs). Montgomery (1901) has suggested that this is to facilitate the temporary union in pairs, or “conjugation” of homologous paternal and maternal chromosomes. In Ascaris megaloecephala var. uninuclus, where the somatic number is only two, the association must necessarily be between homologous chromosomes. The assumption that this “selective pairing” of equivalent chromosomes is universal is supported by the behaviour of the “Heterochromosomes” (Montgomery) of the Hemiptera. These chromosomes, distinguished by their size, are paired before, and single after, the “pseudo-reduction” has taken place. Even more convincing is Sutton’s account of reduction in Brachystola already referred to. Boveri (1904) has suggested that this temporary association of the chromosomes—presumably facilitated by the synapsis—has a much deeper meaning than to ensure their correct distribution between the daughter nuclei in the heterotype mitosis; the associated chromosomes exchanging material in a manner analogous to conjugation in the ascomycetes.

Present Position of the Cell-theory.—Since the time of Schleiden and Schwann a wealth of evidence has accumulated in support of the “cell-theory”—the theory which regards the cell as the unit of organic structure. “The organism consists of many cells.”

9. H. Hennig (1899), T. Montgomery (1898) and F. C. Paulmeir (1899) have suggested the bipartite bivalent halves of the tetrad as being united each by two fibres with the corresponding spindle pole. At the next division, at which the diad is resolved into its constituent univalent chromosomes, the daughter chromosomes are attached to the spindle pole by only one fibre; the two fibres now passing to the opposite poles of the spindle being the same fibres which, in the preceding mitosis, were attached to one and the same pole.

8. Reference may be here made to Rosenberg’s description (1904) of the heterotype mitosis in Diosyn hybrids. In the one parent (Diosyn var. reticulata) the spores have 10 chromosomes (5 in each polyploid; 5 in each spore leaf, 5 in each gamete); while the hybrid itself has a somatic number of 30. The reduced number in the hybrid, however, is not 15 but 20. Of these 10 are large and 10 small, the latter presumably representing the somatic number, and hence unpaired, chromosomes of the D. rotundifolia parent.

7. In their 1905 paper J. B. Farmer and J. E. S. Moore describe two successive synaptic stages (e.g. Elasmobranchs), the first during the contraction of the spireme, the second during the looping up of the bivalent segments. (In this paper the authors suggest the term “Meiosis” or “Meiotic phase” for the nuclear changes accompanying the two maturation divisions in plants and animals (see above, reduction).)
morphologically, of cells, and subsists, physiologically, by means of the "reciprocal action" of the cells,"—this is the cell standpoint of Schleiden and Schwann, and it is an exaggeration to say that this same conception has dominated the cell-theory almost to the present day. ¹ The frequently striking correlation between cell-division and cell-differentiation in development has caused this process to be regarded as dependent on cell-division, while a wholly exaggerated importance has been attached to the distinction between "unicular" and "multicellular" organisms—between "intercellular" and "intracellular" organs. ² The influence of the "cells" upon one another, the subdivision of the cell's growth, division and differentiation, to the requirements of the whole organism—seen in normal growth, but nowhere more strikingly than in development and regeneration—is, however, very difficult of explanation in terms of the cell-theory as this was, until quite recently, generally understood. The very elaborate regional differentiation of the protoplasm often seen in the Protozoa sufficiently indicate that multicellular structure is no essential condition for complex regional differentiation. That the regional differentiation of the protoplasm in the Monera should usually correspond with cell-limits is scarcely surprising. Nor is it to be wondered at, that, with so convenient a mechanism for segregation to hand as cell-division, the progressive differentiation seen during development should often appear to go hand in hand with this process. In recent years, however, evidence has been steadily accumulating to show that this association between cell-division and regional differentiation of the protoplasm in development is a formal one— as casual, and as natural, as the correspondence between cell-limits and regional differentiation in the formed tissues. The fact that the regional differentiation may be foreshadowed in the egg before cleavage begins,—that as Driesch has shown, the mode of cleavage may be artificially altered without affecting the ultimate organization of the embryo,—and many other similar observations, tend to emphasize the importance of the "organism" standpoint (C. O. Whitman, 1903, p. 642) in contradistinction to the widely prevalent "cell" standpoint. ³ The occurrence of syncytial organs and organisms, and the increasing frequency with which protoplasmic continuity is being demonstrated between all kinds of cells, are facts tending in the same direction. In the plant kingdom the growth of the mass has been recognized as the primary factor in development; ⁴ die Pflanze bildet Zellen, nicht die Zelle bildet Pflanzen (de Bary). For the animal kingdom this "Inadequacy of the Cell-Theory of Development" has been maintained amongst others by Whitman, ⁵ and by Adam Sedgwick. ⁶ The latter author, mainly as the result of work on the development of Peripaties and of Elasmobranch embryos, regards the developing embryo as a continuous protoplasmic reticulum, for the nuclei of which the limiting epithelial layers constitute as it were a breeding ground. Differentiation is a regional specialization of this nucleated meshwork, and is not to be regarded as the result of the proliferation and subsequent specialization of cells predestined by cleavage for this end. It is possible to suggest a mechano-physical explanation of many of the facts of many Ctenophorae, Annelids, Gastropods and Nematodes. See the papers by Lilly (1901), Conkin (1902), &c., and especially Wilson on "Dentalium," Journ. of Exp. Zool., No. 1, 1904. Hofmeister, de Bary, Sachs, &c. Loc. cit. ⁷ Quart. Journ. Micro. Science, 1894, vol. xxxvii.

¹ Whitman, Jour. Morph., 1903.
² This "Precocious segregation," (Lankester, 1877) is well seen in the eggs of many Ctenophorae, Annelids, Gastropods and Nematodes. See the papers by Lilly (1901), Conkin (1902), &c., and especially Wilson on "Dentalium," Journ. of Exp. Zool., No. 1, 1904. Hofmeister, de Bary, Sachs, &c. Loc. cit.

CZARNIECKI, STEPHEN (1599–1665), Polish general, learnt the science of war under Stanislaw Koniecpolski in the Prussian campaigns against Gustavus Adolphus (1626–1629), and under Wladislaus IV. in the Muscovite campaign of 1633. On the 15th of April 1648 he was one of the many Polish officers who fell into the hands of Chmielnicki at the battle of “Yellow Waters,” and was sent in chains to the Crimea, whence he was ransomed in 1649. He took an active part in all the subsequent wars with the Cossacks and received more disfiguring wounds than any other commander. When Charles X. of Sweden invaded Poland in 1655, Czarniecki distinguished himself by his heroic defence of Cracow, which he only surrendered under the most honourable conditions. His energy and ability as a leader of guerrillas hampered Charles X. at every step, and though frequently worsted he from time to time inflicted serious defeats upon the Swedes, notably at Jaroslaw and at Kozienice in 1656. Under his direction the popular rising against the invader ultimately proved triumphant. It was he who brought King John Casimir back from exile and enabled him to regain his lost kingdom. It was against his advice that the great battle of Warsaw was fought, and his subsequent strategy neutralized the ill effects of that national disaster. On the retirement of the Swedes from Cracow and Warsaw, and the conclusion of the treaty of Copenhagen with the Danes, he commanded the army corps sent to drive the troops of Charles X. out of Poland and greatly contributed to the ultimate success of the Allies.

On the conclusion of peace of Olberg, which adjusted the long outstanding differences between Poland and Sweden, Czarniecki was transferred to the eastern frontier where the war with Muscovy was still raging. In the campaign of 1660 he won the victories of Polocka and Lachowicza and penetrated to the heart of the enemy's country. The diet of 1661 publicly thanked him for his services; the king heaped honours and riches upon him, and in 1665 he was appointed acting commander-in-chief of Poland, but died a few days after receiving this supreme distinction. By his wife Sophia Kobierzycza he left two daughters. Czarniecki is rightly regarded as one of the most famous of heroic Poland's great captains, and to him belongs the chief merit of extricating her from the difficulties which threatened to overwhelm her during the disastrous reign of John Casimir. Czarniecki raised partisan-warfare to the dignity of a science, and by his ubiquity and tenacity demoralized and exhausted the regular armies to which he was generally opposed.

See Ludwik Jenike, Stephen Czarniecki (Pol.)(Warsaw, 1891); Michal Stefan Krawiecki, History of Stephen Czarniecki (Pol.)(Cracow, 1899).

CZARTORYSKI, ADAM GEORGE, PRINCE (1770–1861), Polish statesman, was the son of Prince Adam Czarski Czartoryski and Isabella Fleming. After a careful education at home by eminent specialists, mostly Frenchmen,1 he first went abroad in 1786. At Gotha he heard Goethe read his Iphigenie auf Tauris, and made the acquaintance of the dignified Herder and “fat little Wieland.” In 1789 he visited England with his mother, and was present at the trial of Warren Hastings. On a second visit in 1793 he made many acquaintances among the English aristocracy and studied the English constitution. In the interval between these visits he fought for his country during the war of the second partition, and would subsequently have served under Kosciusko also had he not been arrested on his way to Poland at Brussels by the Austrian government. After the third partition the estates of the Czartoryski were confiscated, and in May 1795 Adam and his younger brother Constantine were summoned to St Petersburg; latter in the year they were commanded to enter the Russian service, Adam becoming an officer in the horse, and Constantine in the foot guards. Catherine was so favourably impressed by the youths that she restored them part of their estates, and in the beginning of 1796 made them gentlemen in waiting. Adam had already met the grand duke Alexander at a ball at the princess Golitsyn's, and the youths at once conceived a strong “intellectual friendship” for each other. On the accession of the emperor Paul, Czartoryski was appointed adjutant to Alexander, now Cesarевич, and was permitted to visit his Polish estates for three months. At this time the one of the Russian court was extremely liberal, humanitarian enthusiasts like Peter Volkonsky and Nikolai Novosiltsov possessing great influence.

Throughout the reign of Paul, Czartoryski was in high favour and on terms of the closest intimacy with the emperor, who in December 1798 appointed him ambassador to the court of Sardina. On reaching Italy Czartoryski found that the monarch to whom he was accredited was a king without a kingdom, so that the outcome of his first diplomatic mission was a pleasant tour through Italy to Naples, the acquisition of the Italian language, and a careful exploration of the antiquities of Rome. In the spring of 1801 the new emperor Alexander summoned his friend back to St Petersburg. Czartoryski found the tsar still suffering from remorse at his father's assassination, and incapable of doing anything but talk religion and politics to a small circle of private friends. To all remonstrances he only replied "There's plenty of time." The senate did most of the current business; Peter Vasilievich Zavadovsky, a pupil of the Jesuits, was minister of education. Alexander appointed Czartoryski curator of the academy of Vilna (April 3, 1803) that he might give full play to his advanced ideas. Jenike, however, to give much importance to education, for from the beginning of 1805, as adjunct of foreign affairs, he had the practical control of Russian diplomacy. His first act was to protest energetically against the murder of the duc d'Enghien (March 20, 1804), and insist on an immediate rupture with France. On the 7th of June the French minister Hedouville quitted St Petersburg; and on the 11th of August a note dictated by Czartoryski to Alexander was sent to the Russian minister in London, urging the formation of an anti-French coalition. It was Czartoryski also who framed the Convention of the 6th of November 1804, whereby Russia agreed to put 115,000 and Austria 235,000 men in the field against Napoleon. Finally, on the 11th of April 1805 he signed an offensive-defensive alliance with England. But his most striking ministerial act was a memorial written in 1805, but otherwise undated, which aimed at transforming the whole map of Europe. In brief it amounted to this. Austria and Prussia were to divide Germany between them. Russia was to acquire the Dardanelles, the Sea of Marmora, the Bosphorus with Constantinople, and Corfu. Austria was to have Bosnia, Wallachia and Rugasa. Montenegro, enlarged by Mostar and the Ionian Islands, would form a separate state. England and Austria together were to maintain the equilibrium of the world. In return for their acquisitions in Germany, Austria and Prussia were to consent to the erection of an autonomous Polish state extending from Danzig to the sources of the Vistula, under the protection of Russia. Fantastic as it was in some particulars, this project was partly realized2 in more recent times, and it presented the best guarantee for the independent existence of Poland which had never been able to govern itself. But in the meantime Austria had come to an understanding with England as to subsidies, and war had begun.

In 1805 Czartoryski accompanied Alexander both to Berlin and Olmütz as chief minister. He regarded the Berlin visit as a blunder, chiefly owing to his profound distrust of Prussia; but Alexander ignored his representations, and in February 1807 he lost favour and was superseded by Andrei Eberhard Budberg. But though no longer a minister Czartoryski continued to enjoy Alexander's confidence in private, and in 1810 the emperor candidly admitted to Czartoryski that his policy in 1805 had been erroneous and he had not made a proper use of his opportunities. The same year Czartoryski quitted St Petersburg for ever; but the personal relations between him and Alexander were never better. The friends met again at Kalisch shortly before the signature of the Russo-Prussian alliance of the 20th of February 1813, and Czartoryski was in the emperor's suite at Paris in 1814, and rendered his sovereign services at the congress of Vienna.

On the election of the congressional kingdom of Poland 1 e.g. Austria obtained Bosnia, and Montenegro has been enlarged.

1 Among them was the famous democrat Dupont de Nemours.
every one thought that Czartoryski, who more than any other man had prepared the way for it, would be its first governor-general, but he was content with the title of senator-palatine and a share in the administration. In 1817 the prince married Anna Sapiezanka, the wedding leading to a duel with his rival Pac. On the death of his father in 1823 he retired to his ancestral castle at Pulawy; but the Revolution of 1830 brought him back to public life. As president of the provisional government he summoned (Dec. 18th, 1830) the Diet of 1831, and after the termination of Chlopicki’s dictatorship was elected chief of the supreme council by 121 out of 138 votes (January 30th). On the 16th of September his disapproval of the popular excesses at Warsaw caused him to quit the government after sacrificing half his fortune to the national cause; but it must be admitted that throughout the insurrection he did not act up to his great reputation. Yet the energy of the secessionist statesman was wonderful. On the 23rd of August he joined Girolamo Ramorino’s army-corps as a volunteer, and subsequently formed a confederation of the three southern provinces of Kalisch, Sandomir and Cracow. At the end of the war he emigrated to France, where he resided during the last thirty years of his life. He died at his country residence at Montferrand, near Meaux, on the 15th of July 1861. He was the grandson of Fryderyk Czartoryski (1696-1775), and a daughter Isabella, who married Jan Dzialyński in 1857. The principal works of Czartoryski are Essai sur la diplomatie (Marseilles, 1830); Life of J. U. Niewiadom (Pol.) (Paris, 1850); Alexander J. et Czartoryski: correspondance... et conversations (1801-1823) (Paris, 1865); Mémoires et correspondance avec Alexandre I., with preface by C. de Mazade, 2 vols. (Paris, 1887); an English translation Memoirs of Czartoryski, &c., edited by A. Giełguch, with documents relating to his negotiations with Pitt, and conversations with Palmerston in 1832 (2 vols., London, 1888).

See Bronisław Zaleski, Life of Adam Czartoryski (Pol.) (Paris, 1887); Ludomicz Gadon, Prince Adam Czartoryski (Pol.) (Cracow, 1892); Ludovicz Dobicki, Pulawy, vol. iv.; Ludomir Gadon, Prince Adam Czartoryski during the Insurrection of November (Pol.) (Cracow, 1900).

CZARTORYSKI, Fryderyk Michal, Prince (1660-1775), Polish statesman, was born in 1660. Of small means and no position, he owed his elevation in the world to extraordinary ability, directed by an energetic but patriotic ambition. After a careful education on the best French models, which he completed at Paris, Florence and Rome, he attached himself to the court of Dresden, and through the influence of Count Fleming, the leading minister there, obtained the vice-chancellorship of Lithuania and many other dignities. Czartoryski was one of the many Polish nobles who, when Augustus II. was seriously ill at Bialyvostok in 1727, signed the secret declaration guaranteeing the Polish succession to his son; but this did not prevent him from repudiating his obligations when Stanislaus Leszczyński was placed upon the throne by the influence of France in 1733. When Stanislaus abdicated in 1735 Czartoryski voted for Augustus III. (of Saxony), who gladly employed him and his family to counteract the influence of the irreconcilable Potokis. For the next forty years Czartoryski was certainly the leading Polish statesman. In foreign affairs he was the first to favour an alliance with Russia, Austria and England, as opposed to France and Prussia—a system difficult to formulate, not always beneficial to Poland or Saxony. In Poland Czartoryski was at the head of the party of reform. His palace was the place where the most promising young gentlemen of the day were educated and sent abroad that they might return as his coadjutors in the great work. His plan aimed at the restoration of the royal prerogative and the abolition of the liberum veto, an abuse that made any durable improvement impossible. These patriotic endeavours made the Czartoryski very unpopular with the ignorant szlacht, but for many years they had the firm and constant support of the Saxony court, especially after Brühl succeeded Fleming.

Czartoryski reached the height of his power in 1732 when he was entrusted with the great seal of Lithuania; but after that date the influence of his rival Mniszech began to prevail at Dresden, whereupon Czartoryski sought a reconciliation with his political opponents at home and foreign support both in England and Russia. In 1755 he sent his nephew Stanislaus Poniatowski to St Petersburg as Saxon minister, a mission which failed completely. Czartoryski’s philo-Russian policy had by this time estranged Brühl, but he frustrated all the plans of the Saxon court by dissolving the diets of 1760, 1761 and 1762. In 1763 he went a step farther and proposed the dethronement of Augustus III., who died the same year. During the ensuing interregnum the prince chancellor laboured night and day at the convocation diet of 1764 to reform the constitution, and it was with displeasure that he saw his incompetent nephew Stanislaus finally elected king in 1765. But though disgusted with the weakness of the king and obliged to abandon at last all hope of the amelioration of his country, Czartoryski continued to hold office till the last; and as chancellor of Lithuania he sealed all the partition treaties. He died in the full possession of his faculties and was considered by the Russian minister Repnin “the soundest in the kingdom.” It is a mistake, however, to regard Czartoryski as the sole reforming statesman of his day, and despite his great services there were occasions when he failed to preserve the balance of the state. His foreign policy, moreover, was very vacillating, and he changed his “system” more frequently perhaps than any contemporary diplomatist. But when all is said he must remain one of the noblest names in Polish history.

See the Correspondence of Czartoryski in the Collections of the Russian Historical Society, vols. 7, 10, 13, 48, 51, 67 (St Petersburg, 1890, &c.); Władysław Tadeusz Kisielewski, Reforms of the Czartoryski (Pol.) (Carl Heinrich Heyking, Aus Polens und Kurland's letzten Tagen (Berlin, 1897); Ludwic Denbicki, Pulawy (Pol.) (Lemberg, 1897-1898).

CZECH (in Bohemian, Čech), a name which signifies an inhabitant of Čechy, the native designation of Bohemia. The Czechs belong to the Slav race, and according to the usually accepted division of the language form together with the Slovaks and the almost extinct Lusatians, the group of the Western Slavs. Speaking generally, it can be said that the Czechs inhabit a large part of Bohemia, a yet larger part of Moravia, parts of Silesia—both Austrian and Prussian—and extensive districts in northern Hungary. In the 19th century the Czechs of Hungary—much to their own detriment—developed a written language that differs slightly from that used in Bohemia, but as regards their race they are identical with the Bohemians and Moravians. Beyond the borders of this continuous territory there are many Czechs in Lower Austria. Vienna in particular has a large and increasing Czech population. There are also numerous Czechs in Russia, particularly Volhynia, in the United States—where a large number of newspapers and periodicals are published in the Czech language—and in London. Though the statistics are very uncertain and trustworthy, it can be stated that the Czechs number about eight millions.

The period at which the Czechs settled in Bohemia is very uncertain; all theories, indeed, with regard to the advent of the Slavs in northern and eastern Europe are merely conjectural. Lusatia, however, it is generally accepted as a fact that all Bohemia was originally inhabited by Celtic tribes who were succeeded by the Germanic Marcomanni, and later by the Slavic Czechs. According to a very ancient tradition reproduced in the book of Cosmas, the earliest Bohemian chronicle, the Czechs arrived in Bohemia led by their eponymous chief Čechus, and first settled on the Říp Hill (Georgberg) near Roudnice. It is a strange proof of the intense obscurity of the earliest Bohemian history that Cosmas, writing at the beginning of the 12th century, is already unaware of the existence of pre-Slavic inhabitants of Bohemia.

It is historically certain that the Czechs inhabited parts of Bohemia as early as the 6th century. In the absence of all historical evidence, modern Czech scholars have endeavoured by other means to throw some light on the earliest period of the
CZECH

Czechs. By craniole studies and a thorough examination of the fields where the dead were burnt (in Czech 9trone pole), still found in some parts of Bohemia, they have arrived at the conclusion that parts of the country were inhabited by Czechs, or at least by Slavs, long before the Christian era, perhaps about the year 500 B.C.

It is certain that the Slavs at the time when they first appeared in history had a common language, known as the ancient Slavic (práslovansky) language. When in the course of time the Slavs occupied various countries, which were often widely apart, different dialects arose among them, many of which were influenced by the language of the neighbouring non-Slavic populations. Thus the Czech language from an early period absorbed many German words. It is probable that the development of the Czech language as an independent one, was very gradual. Existent documents, such as the hymn to St Wenceslas, which belongs to the second half of the 10th century, are written partly in old-Slavic, partly in Czech. When the Slavs first occupied Bohemia, they were probably divided into several tribes, some of which the Czechs, who inhabited Prague and the country south of it, would probably have cultivated. It is probable that these smaller tribes were only gradually subdued by the Czechs and that some of them had previously to their absorption adopted special dialects. The Netolice, Lučani, Pšovane, Sedlčani appear to have been among the more important tribes who were forced to acknowledge the supremacy of the Czechs, and it may be conjectured that their language for a time differed slightly from that of their conquerors. The Czech language has, like all Slavic ones, a strong tendency to develop dialects; this was the case at the time of its first appearance as an independent language, and has to a certain extent continued up to the present day. The dialects of Moravia and the northern districts of Hungary still show variations from the generally accepted forms of the Czech language, though since the foundation of the Czech university of Prague this—at least among the educated classes—is no longer true to the same extent as it formerly was. The Czech language at the time of its formation naturally remained closest to those other Slav-speaking countries which were geographically its neighbours, the Poles and the Lusatians, and it may be said that this is still the case. The Czech language at the time when in the 12th and 13th centuries it first appears as a separate and distinct one, differed considerably from that of the present day. Ancient Czech had several diphthongs, such as: ia, ie, in, uo and au, that are unknown to the present language. The letter “l” had a threofold sound, and besides the letters b, p, m, v, the softer forms b’, p’, m’, v’ were also in existence. The letter g (as in other Slav languages) was often used where modern Czechs employ the letter h. Ancient Bohemian had three numbers, the singular, plural and dual; of the dual only scant vestiges remain in modern Czech.

Once it had obtained its independence, the Czech language developed rapidly, and the philosophical and theological writings of Thomas of Štítný (1331-1401) proved that it could already be used even for dealing with the most abstract subjects, though Štítný was blamed by the monks for not writing in Latin, as was then customary. The Czech language is greatly indebted also to John Hus, whose best and most original works were written in the language of his country. Hus showed great interest in the orthography and grammar of his language, and has devoted an interesting treatise entitled “Ortagraphia bohemia” to it. As already mentioned, the Czech language had sprung from diverse dialects, and Hus endeavoured to establish uniformity. To the Bohemian reformer is also due the system of so-called diacritic marks—such as ě, ě, ğ—which with some modifications are still in use. The Latin characters which were in the earliest times, as again at the present day, used when writing Czech, are quite unable to reproduce some sounds peculiar to Slavic languages. This was remedied by the introduction of these marks, and Hus’s system of orthography became known as the diacritic one. The Bohemian reformer, zealous for the purity of the language of his country, often in his sermons inveighed quaintly and vehemently against those who defiled the Czech language by introducing numerous “Germanisms.” A century later the Czech language was largely indebted to the then recently founded community of the Bohemian (or as they were also often called, Moravian) brethren. A member of the community, Brother John Blažkov, wrote in 1571 a Grammatika Česká, that still has considerable philological interest. It contains a full account of the construction of the Czech language, based on Latin grammar, with which the writer was thoroughly acquainted. Divines belonging to the same community also at the end of the 16th century published at Kralice in Moravia a complete Czech version of the Old and New Testaments. Together with the Labírint Strěla (Labyrinth of the World) of Komensky (Comenius), who was also a member of the brotherhood, it can be considered a model of the Czech language in the period immediately preceding its downfall.

The Czechs have always enthusiastically upheld the language of their country. In ancient Czech, indeed, the same word jazyk denotes both “nation” and “language.” As late as in 1608 a decree of the estates of Bohemia declared that Czech was the only official and recognized state-language; those who wished to acquire citizenship in the country should be obliged to acquire the knowledge of it. While all patriots thus supported the national language, it was greatly disliked by the absolutists who were opposed to the ancient free constitution of Bohemia, as well as by all who favoured the Church of Rome. The overthrow of Bohemian independence at the battle of the White Mountain (1620) was therefore shortly followed by the decline of the Czech language. All Czech writings which could be found were destroyed by the Austrian authorities as being tainted with heresy, while no new books written in Czech appeared, except occasional prayer-books and almanacs. For these scanty writings the German so-called “Schawbach” characters were used, and this custom only ceased in the middle of the 19th century. The Czech language, for some time entirely excluded from the schools, all but ceased to be written, and its revival at the beginning of the 19th century was almost a resurrection. The first originator of the movement, Joseph Dobrovský or Dubravsky (1753-1829) seems himself, at least at the beginning of his life, to have considered it impossible that Czech should again become a widely-spoken language, and one whose literature could successfully compete with that of larger countries. Yet it was the works of this “patriarch of Slavic philology” which first drew the attention of the half-forgotten Czech language. Dobrovský’s work was afterwards continued by Kolar, Jungmann, Palaeyk, Šafařek, and many others, and Czech literature has, both as regards its value and its extension, reached a height that in the middle of the 19th century would have appeared incredible.

• Though met by constant opposition on the part of the Austrian authorities, the Czechs have succeeded in re-establishing the use of their language in many of the lower and middle schools of Bohemia and Moravia, and the foundation of a Czech university at Prague (1882-1884) has of course contributed very largely to the ever-increasing expansion of the Czech language. The national language has at all times appeared to the Bohemians as the palladium of their nationality and independence, and the movement in favour of the revival of the Czech language necessarily became a political one, as soon as circumstances permitted. The friends of the national language at the beginning of the 19th century were generally known as the vlastenci (patriots), but when in 1848 representatives of many parts of Austria met at Vienna, the deputies of Bohemia—with the exception of the Germans—formed what was called the national or Czech party. Parliamentary government did not at that period long survive, and at the end of the year 1851 absolutism had been re-established. In 1860 a new attempt to establish constitutional government in Austria was made, and representatives of the Czech party appeared at the provincial diet of Prague and the central parliament at Vienna. The Czech party endeavoured to obtain the re-establishment of the ancient
Bohemian constitution, but, allied as they were with a large part of the Bohemian nobility, it was their policy to maintain a somewhat conservative attitude. After having asserted themselves for a considerable time from the parliament at Vienna, the legality of which they denied, the Czech deputies reappeared in Vienna in 1879, and, together with the representatives of the Bohemian nobility, formed there what was known as the Český Klub.

While the Czechs for a time continued united at Vienna, a schism among them had some time previously occurred at Prague. Dissatisfied with the policy of the Czechs, a new party had been formed in Bohemia which affected more advanced views and became known as the "Young Czech" party. The more conservative Czechs were henceforth known as the "Old Czechs." The "Young Czechs," when the party first became independent in 1872, had thirty-five representatives in the diet of Prague, but at the elections of 1874 their number was reduced to seven. They continued, however, to gain in strength, and obtained for a long time a large majority in the diet, while the Old Czech party for a considerable period almost disappeared. In Vienna also the Old Czech party gradually lost ground. Its leader Dr Rieger, indeed, obtained for the Czechs certain concessions which, underrated at the time, have since proved by no means valueless. The decision of the Old Czech party to take part at a conference in Vienna under the presidency of Count Taaffe—their Austrian adherent—which was to settle the national differences in Bohemia, caused its complete downfall.

The proposals of the Vienna conference were rejected with indignation, and the Old Czechs, having become very unpopular, for a time ceased to contest the elections for the legislative assemblies of Prague and Vienna. The victorious Young Czechs, however, soon proved themselves very unskilful politicians. After very unsuccessfully assuming for a short time an attitude of insinuating opposition, they soon became subservient to the government of Vienna to an extent which the Old Czechs had never ventured. Dr Kramář, in particular, as leader of the Young Czech party, supported the foreign policy of Austria even when its tendency was most hostile to the interests of Bohemia. The Vienna government has, in recent years, as regards internal affairs, also adopted a policy very unfavourable to the Czech race. Even the continuance of some of the concessions formerly obtained by the Old Czechs has become doubtful.

At the elections to the diet of Prague which took place in March 1908, the Young Czechs lost many seats to the Old Czechs, while the Agrarians, Clericals and Radicals were also successful.

**CZENSTOCHOWA—CZERNY**

The town manufacture cotton, cloth and paper, and do a lively business in rosaries, images, scapularies and so forth.

**CZERNOWITZ** (Rum. Cernăuți), the capital of the Austrian duchy of Bukovina, is situated 57 m. E. of Krakoŭ and 164 m. S.E. of Lemberg by rail. Pop. (1900) 60,619. It is picturesquely situated on a height above the right bank of the river Pruth, which is crossed here by two bridges, of which one is a railway bridge. Czernowitz is a clean, pleasant town of recent date, and is the seat of the Greek Orthodox bishop or metropolitan of Bukovina. The principal buildings include the Greek Orthodox cathedral, finished in 1864 after the model of the church of St Isaac at St Petersburg; the Armenian church, in a mixed Gothic and Renaissance style, consecrated in 1875; a handsome new Jesuit church, and a new synagogue in Moorish style, built in 1877. The most conspicuous building of the town is the Episcopal palace, in Byzantine style, built in 1864–1875, which is adorned with a high tower and possesses a magnificent reception hall. In one of the public squares stands the Austrian monument, executed by Pekary and erected in 1875 to commemorate the centenary of Austria's possession of Bukovina. It consists of a marble statue of Austria erected on a pedestal of green Carpathian sandstone. The Francis Joseph University, also opened in 1875, had 50 lecturers and over 500 students in 1901. The language of instruction is German, and it possesses three faculties: theology, law and philosophy. The industry is not very developed, and consists chiefly in corn-milling and brewing. An active trade is carried on in agricultural produce, wood, wool, cattle and spirits. Czernowitz has a mixed population, which consists of Germans, Ruthenians, Rumanians, Poles, Jews, Armenians and Gypsies. The town presents, therefore, a cosmopolitan and on market days a very varied appearance, when side by side with people turned out in the latest fashions from Paris or Vienna, we meet peasants of various nationalities, attired in their national costume, intermingled with very scantly-clad Gypsies.

On the opposite bank of the Pruth, at a very little distance to the N., is situated the town of Sadagara (pop. 4512, mostly Jews), where a famous cattle fair takes place every year.

Czernowitz was at the time of the Austrian occupation (1773) an unimportant village. It was created a town in 1786, and at the beginning of the 19th century it numbered only 5000 inhabitants.

**CZERNY, KARL** (1751–1857), Austrian pianist and composer, was born at Vienna on the 21st of February 1791. His father, who was a teacher of the piano, trained him for that instrument from an early age with such success that he performed in public at the age of nine, and commenced his own career as a teacher at fourteen. He was brought under the notice of Beethoven, and was his pupil in the sense in which the great master had pupils. It is perhaps his greatest claim to distinction as a performer that he was selected to be the first to play Beethoven's celebrated Emperor concerto in public. He soon became the most popular teacher of his instrument in a capital which abounded in pianists of the first rank. Among his pupils he numbered Liszt, Theodor Döhler (1814–1843) and many others who afterwards became famous. As a composer he was prolific to an astonishing degree, considering the other demands on his time. His works, which included every class of composition, numbered 849 at the time of his death. Comparatively few of them possess high merit, and none is the production of genius. He had considerable skill in devising variations for the piano of the display type, and in this and other ways helped to develop the executive power which in the modern school of pianoforte playing seems to have reached the limits of the possible. His various books of exercises, elementary and advanced, of which the best known are the Études de la vitesse, have probably had a wider circulation than any other works of their class. To the theory of music he contributed a translation of Reicha's Traité de composition, and a work entitled Umriss der ganzen Musikgeschichte. Czerny died on the 15th of July 1857 at Vienna. Having no family, he left his fortune, which was considerable, to the Vienna Conservatorium and various benevolent institutions.
D

The fourth letter in the English alphabet occupies the same position in the Latin, Greek and Phoenician alphabets, which represent the preceding stages in its history. The Phoenician name Dala, is represented by the Greek Delta. In form D has varied throughout its career comparatively little. In the earliest Phoenician it is $<\chi$ with slight variations; in most Greek dialects it which has been adopted as the Greek literary form, but in others as e.g. the earliest Attic O or $\chi$. The form with the rounded back, which has passed from Latin into the languages of western Europe, was borrowed from the Greeks of S.W. Italy, but is widely spread also amongst the peoples of the Peloponnesian and of northern Greece. It arises from a form like $\alpha$ when the sides which meet to the right are written or engraved at one stroke. From a very early period one side of the triangle was often prolonged, thus producing a form $\chi$ which is characteristic of Aramaic from 800 n.c. In Greek this was avoided because of the likelihood of its confusion with $\chi$, the oldest form of the symbol for $\omega$, but in the alphabets of Italy—which were borrowed from Etruscan—this form actually takes place. Etruscan had no sound corresponding to the symbol D (in inscriptions written from right to left, $\chi$), and hence used it as a by-form for $\chi$, the symbol for $\omega$. The Oscans and Umbrians took it over in this value, but having the sound $d$ they used it for the symbol for $\omega$ (in Umbrian, $\alpha$ in Osco).

The sound which D represents is the voiced dental corresponding to the unvoiced t. The English d, however, is not a true dental, but is really pronounced by placing the tongue against the sockets of the teeth, not the teeth themselves. It thus differs from the d of French and German, and in phonetic terminology is called an alveolar. In the languages of India where both true dentals and alveolars are found, the English d is represented by the alveolar symbol (transliterated $\delta$). Etymologically in genuine English words $d$ represents in most cases the original Indo-European language, but in some cases an original t. In many languages d develops as an aspirate after it, and this $\delta$ becomes then a voiced spirant ($\delta$), the initial sound of there and that. This has occurred widely in Semitic, and is found also in languages like modern Greek, where d, except after v, is always spirant, $\delta v v$ (= not) being pronounced like English then. As the mouth position for d differs from that for d only by the breath being allowed to escape past one or both sides of the tongue, confusion has arisen in many languages between $d$ and $l$, the best-known being cases like the Latin lacrima as compared with the Greek $\delta k r v$. The English tear and the forms of other languages show that $d$ and not $l$ is the more original sound. Between vowels in the ancient Umbrian d passed into a sound which was transliterated in the Latin alphabet by rs; this was probably a sibilant r, like the Bohemian z. In many languages it is unvoiced at the end of words, thus becoming almost or altogether identical with t. As an abbreviation it is used in Latin for the praenomen Decimus, and under the empire for the title Divus of certain deceased emperors. As a Roman numeral ($\delta 500$) it is only the half of the old symbol $\Theta$ (= 1000); this was itself the old form of the Greek $\phi$, which was useless in Latin as that language had no sound identical with the Greek $\phi$.

(D.G.)

Dacca, a city of British India, giving its name to a district and division of Eastern Bengal and Assam. It was the capital of that province on its creation in October 1805. The city is 254 m. N.E. by E. of Calcutta, on an old channel of the Ganges. Railway station, 10 m. from the terminus of the river steamers at Narayanganj. The area is about 8 sq. m. The population in 1901 was 90,542. The ruins of the English factory, St Thomas's church, and the houses of the European residents lie along the river banks. Of the old fort erected by Islam Khan, who in 1608 was appointed nawab of Bengal, and removed his capital from Rajmahal to Dacca, no vestige remains; but the jail is built on a portion of its site. The principal Mahommedan public buildings, erected by subsequent governors and now in ruins, are the Kattra and the Lal-bagh palace—the former built by Sultan Mahommed Shuja in 1645, in front of the chauk or market place. Its extensive front faced the river, and had a lofty central gateway, flanked by smaller entrances, and by two octagonal towers rising to some height above the body of the building. The Lal-bagh palace was commenced by Azam Shah, the third son of the emperor Aurungzeb. It originally stood close to the Buriganga river; but the channel has shifted its course, and there is now an intervening space covered with trees between it and the river. The walls on the western side, and the terrace and battlements towards the river, are of a considerable height, and present a commanding aspect from the water. These outworks, with a few gateways, the audience hall and the baths, were the only parts of the building that survived in 1840. Since then their dilapidation has rapidly advanced; but even in ruin they show the extensive and magnificent scale on which this princely residence was originally designed. It appears never to have been completed; and when Jean Baptiste Tavernier visited Dacca (c. 1662), the palace was resting on a temporary wooden building in its court. The English factory was built about that year. The central part of the old factory continued to be used as a court-house till the 19th century, but owing to its ruinous state it was pulled down in 1829 or 1830; in 1840 the only portion that remained was the outward wall. The French and Dutch factories were taken possession of by the English in the years 1778 and 1781 respectively. In the mutiny of 1857 two companies of the 73rd Native Infantry which were stationed in the town joined in the revolt, but were overpowered by a small European force and dispersed. The city still shows some signs of its former magnificence. The famous manufacture of fine muslins is almost extinct, but the carving of shells, carried on from ancient times, is an important industry in the city. There are a Government college, a collegiate school and an unaided Hindu college. There is a large settlement of mixed Portuguese descent, known as Feringhis. Many of the public buildings, including the college, suffered severely from the earthquake of the 12th of June 1897; and great damage was done by tornadoes in April of 1888 and 1902.

The district of Dacca comprises an area of 2782 sq. m. In 1901 the population was 2,640,522, showing an increase of 11% in the decade. The district consists of a vast level plain, divided into two sections by the Dhaleswari river. The northern part, again intersected by the Lakshmia river, contains the city of Dacca, and as a rule lies well above flood-level.

Dacca is watered by a network of rivers and streams, ten of which are navigable throughout the year by native cargo boats of four tons burthen. Among them are the Meghna, the Ganges or Padma, the Lakshmia, a branch of the Brahmaputra, the Jamuna, or main stream of the Brahmaputra, the Mendi-Khali, a large branch of the Meghna, the Dhaleswari, an offshoot of the Jamuna, the Ghazi-khali and the Buriganga. The soil is composed of red ferruginous kankar, with a stratum of clay in the more elevated parts, covered by a thin layer of vegetable mould, or by recent alluvium. The Lakshmia is very beautiful, the banks being high and wooded. About 20 m. north of Dacca city, small ridges are met with in the Madhupur jungle, stretching into Mymensingh district. These hills, however, are mere mounds of from 20 to 40 ft. high, composed of red soil containing a considerable quantity of iron ore; and the whole tract is for the most part unproductive. Towards the city the red soil is intersected by creeks and morasses, whose margins yield crops of rice, mustard and til seed; while to the east of the town, a broad, alluvial, well-cultivated plain reaches as far as the junction of the Dhaleswari and Lakshmia rivers. The country lying to the south of the Dacca is the most
fertile part of the district. It consists entirely of rich alluvial soil, annually inundated to a depth varying from 2 to 14 ft. of water. The villages are built on artificial mounds of earth, so as to raise them above the flood-level. The wild animals found in the district comprise a few tigers, leopards and wild elephants, deer, wild pig, porcupines, jackals, foxes, hares, otters, &c. The green monkey is very common; porpoises abound in the large rivers. The manufactures consist of weaving, embroidery, gold and silver work, shell-carving and pottery. The weaving industry and the manufacture of fine Dacca muslins have greatly fallen off, owing to the competition of European piece goods. Forty different kinds of cloth were formerly manufactured in this district, the bulk of which during many years was made from English twist, country thread being used only for the finest muslins. It is said that, in the time of the emperor Jahangir, a piece of muslin, 15 ft. by 3, could be manufactured, weighing only 900 grains, its value being £40. In 1840 the finest cloth that could be made of the above dimensions weighed about 1600 grains, and was worth £10. Since then the manufacture has still further decayed, and the finer kinds are now made at all except to order. The district is traversed by a line of the Eastern Bengal railway, but most of the traffic is still conducted by water. It is a centre of the jute trade. The division of Dacca occupies the delta of the Brahmaputra, which it fills with its delta. It consists of the four districts of Dacca, Mymensingh, Faridpur and Backergunge. Its area is 15,837 sq. m. Its population in 1901 was 10,793,988.

DACE, DARE, or DART (Leuciscus vulgaris, or L. dolobus), a freshwater fish belonging to the family Cyprinidae. It is an inhabitant of the rivers and streams of Europe north of the Alps, but it is most abundant in those of France and Germany. It prefers clear streams flowing over a gravelly bottom, and deep, still water, keeping close to the bottom in winter but disporting itself near the surface in the sunshine of summer. It is preyed upon by the larger predaceous fishes of fresh waters, and owing to its silvery appearance is a favourite bait in pike-fishing. The dace is a lively, active fish, of gregarious habits, and exceedingly prolific, depositing its eggs in May, and June at the roots of aquatic plants or in the gravelly beds of the streams it frequents. Its flesh is wholesome, but is not held in as much estimation. In appearance it closely resembles the roach, usually attaining a length of 8 or 9 in., with the head and back of a dusky blue colour and the sides of a shining silvery aspect, with numerous dark lines running along the backbone; the ventral and anal fins are black, tinged with pale red; and the pectoral and opercular tipped with black. The dace feeds on worms, insects, insect-larvae, and also on vegetable matter. It is abundant in many of the streams of the south of England, but is unknown in Scotland and Ireland. In America the name of dace is also applied to members of other genera of the family; the "horned dace" (Semnotilus atromaculatus) is a well-known variety.

DACH, SIMON (1605–1659), German lyrical poet, was born at Memel in East Prussia on the 29th of July 1605. Although brought up in humble circumstances, he received a careful education in the classical schools of Königsberg, Wittenberg and Magdeburg, and entered the university of Königsberg in 1626 as a student of theology and philosophy. After taking his degree, he was appointed in 1633 Kollaborator (teacher) and in 1636 co-rector of the Domschule (cathedral school) in that city. In 1639 he received the chair of poetry at the university of Königsberg, which he occupied until his death on the 15th of April 1639. In Königsberg he entered into close relations with Heinrich Albert (1604–1651), Robert Reberthyn (the elder), and Sibylle Schwartzen (1622–1688), and with them formed the so-called Königsberger Dichtergruppe. He sang the praises of the house of the electors of Brandenburg in a collection of poems entitled Kurbrandenburgische Rose, Adler, Lüwe and Scepter (1661), and also produced many occasional poems, several of which became popular; the most famous of them is Anke von Tharau öfs, de my gefyllt (rendered by Herder into modern German as Anchen von Tharau), composed in 1637 in honour of the marriage of a friend. Among his hymns, many of which are of great beauty, are the following: Ich bin ja, Herr, in deiner Macht; Ich bin bei Gott in Gnaden durch Christi Blut und Tod, and O, wie selig seid ihr hoch, ihr Frommen.

Editions of Dach's poems have been published by W. Müller (1823), by H. Österrich (for the Stuttgart Literarische Verein, 1876); also selections by the same editor (1876), and in Kürschner's Deutsches Nationalliteratur (1883). See especially the introductions to Österrich's editions; also H. Stehler, Simon Dach, sein Leben und seine ausgeübte Dichtungen (1896).

DACIA, in ancient geography, the land of the Daci, a large district of central Europe, bounded on the N. by the Carpathians, on the S. by the Danube, on the W. by the Tharsus (Theiss), on the E. by the Tavras (Dniester), thus corresponding in the main to the modern Rumania and Transylvania. Towards the west it may originally have extended as far as the Danube where it runs from north to south at Warnitzen (Vacz), while on the other hand Ptolemy puts its eastern boundary as far back as the Hierasus (Sereth). The inhabitants of this district were a Thracian stock, originally called Dacii, a name which after the 4th century B.C. gave place to Daco. Of the other Thracian tribes the Getae (g.e.) were most akin to them in language and manners; by the Greeks the Dacians were usually called Getae, by the Romans Daci. Daci and Tera (Davus, Geta) were common names; Dacian was a considered outside trade, as is shown by the number of foreign coins found in the country.

The Dacians had attained a considerable degree of civilization when they first became known to the Romans. They believed in the immortality of the soul, and regarded death as merely a change of country (μετονομήσαν). Their chief priest held a prominent position as the representative of the deity upon earth; he was the king's chief adviser and his decisions were accepted as final. They were divided into two classes—an aristocracy and a proletariat. The first alone had the right to cover their heads and wore a felt hat (hence tarabostein = τραβοισθείν, ἄφεθαι); they formed a privileged class, and were the predecessors of the Rumanian boyars. The second class, who comprised the rank and file of the army, the peasants and artisans, wore their hair long (κομφραλ, καπλιλα). They dwelt in wooden huts surrounded by palisades, but in later times, aided by Roman architects, built walled strongholds and conical stone towers. Their chief occupations were agriculture and cattle-breeding; horses were mainly used as draught animals. They also worked the gold and silver mines of Transylvania, and carried on a considerable outside trade, as is shown by the number of foreign coins found in the country.

A kingdom of Dacia was in existence at least as early as the beginning of the 2nd century B.C. under a king Oroes. Conflicts with the Bastarnae and the Romans (112–109, 74), against whom they had assisted the Scordisci and Dardani, had greatly weakened the resources of the Dacians. Under Burbista (Boeribista), a contemporary of Caesar, who thoroughly reorganized the army and raised the moral standard of the people, the limits of the kingdom were extended; the Bastarnae and Boii were conquered, and even Greek towns (Olbia, Apollonia) on the Euxine fell into his hands. Indeed the Dacians appeared so formidable that Caesar contemplated an expedition against them, which was prevented by his death. About the same time Burbista was murdered, and the kingdom was divided into four (or five) parts under separate rulers. One of these was Cotiso, whose daughter Augustus is said to have desired to marry and to whom he betrothed his own five-year-old daughter Julia. He is well known from the line in Horace ("Occidit Daci Coticonis agmen," Odes, iii. 8, 19), which, as the ode was written in the 1st of March, 29 B.C., very likely refers to the campaign of Marcus C Marius (38–32), not to that of Cornelius Lentulus, who was not consul till 18. The Dacians are often mentioned under Augustus, according to whom they were compelled to recognize the Roman supremacy. But they were by no means subdued, and in later times seized every opportunity of crossing the frozen Danube and ravaging the province of Moesia. From A.D. 85 to 89 the Dacians were engaged in two wars with the Romans, under Durus or Diurampes, and the great Decebalus, who ruled from 86–87
to 107. After two severe reverses, the Romans, under Tettius Julius, gained a signal advantage, but were obliged to make peace, owing to the defect of Domitian by the Marcomanni. Deccebalus restored the arms he had taken and some of the prisoners and received the crown from Domitian's hands, an apparent acknowledgment of Roman suzerainty. But the Dacians were really left independent, as is shown by the fact that Domitian agreed to purchase immunity from further Dacian inroads by the payment of an annual tribute.

To put an end to this disgraceful arrangement, Trajan resolved to crush the Dacians once and for all. The result of his first campaign (101-102) was the occupation of the Dacian capital Sarmizegethusa (Vârhegy) and the surrounding country; of the second (105-107), the suicide of Deccebalus, the conquest of the whole kingdom and its conversion into a Roman province. The history of the war is given in Dio Cassius, but the best commentary upon it is the famous column of Trajan. According to Marquart, the boundaries of the province were the Tibiscus (Temes) on the W., the Carpathians on the N., the Tyrrhenus (E.), and the Danube on the S., but Brandis (in Pauly-Wissowa's Realencyclopaedie) maintains that it did not extend farthest eastwards than the river Olt (Aluta)—the country beyond belonging to lower Moesia—and not so far as the Theiss westwards, being thus limited to Transylvania and Little Walachia. It was under a governor of prætorian rank, and the legio xii. gemina with numerous auxiliaries had their fixed quarters in the province. To make up for the ravages caused by the recent wars colonists were imported to cultivate the land and work the mines, and the old inhabitants gradually returned. Forts were built as a protection against the incursions of the surrounding barbarians, and three great military roads were constructed to unite the chief towns, while a fourth, named after Trajan, traversed the Carpathians and entered Transylvania by the Rotermum pass. The two chief towns were Sarmizegethusa (afterwards Ulpija Traiana Dacia, Apulonia with capital capite vulnus). With the religion of the Dacians also adopted the language of the conquerors, and modern Rumanian is full of Latin words easily recognisable.

In 129, under Hadrian, Dacia was divided into Dacia Superior and Inferior, the former comprising Transylvania, the latter Little Walachia, with procurators, probably both under the same prætorian legate (according to Brandis, the procurator of Dacia inferior was independent, but see A. Domaszewski in Rhénischen Museum, xlvi., 1893). Marcus Aurelius divided it into three (tres Dacie): Porolissensis, from the chief town Porolissum (near Mojrad), Apulensis from Apulum and Malauensis (site unknown). The tres Dacie formed a commune in so far that they had a common capital, Sarmizegethsua, and a common diet, which discussed provincial affairs, formulated complaints and adjusted the incidence of taxation; but in other respects they were practically independent provinces, each under an ordinary procurator, subordinate to a governor of consular rank.

The Roman hold on the country was, however, still precarious. Indeed it is said that Hadrian, conscious of the difficulty of retaining it, had contemplated its abandonment and was only deterred by consideration for the safety of the numerous Roman settlers. Under Gallienus (256), the Goths crossed the Carpathians and drove the Romans from Dacia, with the exception of a few fortified places between the Temes and the Danube. No details of the event are recorded, and the chief argument in support of the statement in Ruf(f)ius Festus that "under the Emperor Gallienus Dacia was lost," is the sudden cessation of Roman inscriptions and coins in the country after 256. Aurelian (270-275) withdrew the troops altogether and settled the Roman colonists on the south of the Danube, in Moesia, where he created the province Dacia Aureliana. This was subsequently divided into Dacia Ripensis on the Danube, with capital Ratiaria (Ardeal in modern Roumania), and Dacia Superior with capital Sardica (Sofoaia, the capital of Bulgaria), the latter again being subdivided into Dardania and Dacia Mediterranea.

Blachs.)

DACIER, ANDRÉ (1651-1722), French classical scholar, was born at Castres in upper Languedoc, on the 6th of April 1651. His father, a Protestant advocate, sent him first to the academy of Puy Laurens, and afterwards to Saumur to study under Tanneguy Lefèvre. On the death of Lefèvre in 1672, Dacier removed to Paris, and was appointed one of the editors of the Delphine series of the classics. In 1683 he married Anne Lefèvre, the daughter of his old tutor (see below). In 1695 he was elected member of the Academy of Inscriptions, and also of the French Academy; not long after, as payment for his share in the "medieval" history of the king's reign, he was appointed keeper of the library of the Louvre. He died two years after his wife, on the 18th of September 1722. The most important of his works were his editions of Pompeius Festus and Verrius Flaccus, and his translations of Horace (with notes), Aristotle's Poetics, the Electa and Odeipus colonus of Sophoehes, Epictetus, Hippocrates and Plutarch's Lives. His wife, Anne Lefèvre (1654-1720), French scholar and translator from the classics, was born at Saumur, probably in March 1654. On her father's death in 1672 she removed to Paris, carrying with her part of an edition of Callimachus, which she afterwards published. This was so well received that she was engaged as one of the editors of the Delphine series of classical authors, in which she edited Florus, Dictys Cretensis, Aurelius Victor and Eutropius. In 1681 she appeared her prose version of Anacreon and Sappho, and in the next few years she published prose versions of Terence and some of the plays of Plautus and Aristophanes. In 1684 she and her husband retired to Castres, with the object of devoting themselves to theological studies. In 1685 the result was announced in the conversion to Roman Catholicism of both M. and Mme Dacier, who were rewarded with a pension by the king. In 1690 appeared the prose translation of the "Odyssey," which for its position she occupies in French literature. The appearance of this version, which made Homer known for the first time to many French men of letters, and among others to A. Houdart de la Motte, gave rise to a famous literary controversy. In 1714 la Motte published a poetical version of the Iliad, abridged and altered to suit his own taste, together with a Discours sur Homère, stating the reasons why Homer failed to satisfy his critical taste. Mme Dacier replied in the same year in her work, Des causes de la corruption du goût. La Motte carried on the discussion with fight gaiety and badinage, and had the happiness of seeing his views supported by the abbé Jean Terrasson, who in 1715 produced two volumes entitled Dissertation critique sur l'Iliade, in which he maintained that science and philosophy, and especially the science and philosophy of Descartes, had so developed the human mind that the poets of the 18th century were measurably superior to those of ancient Greece. In the same year Père C. Buffier published Homère en arithmétique, in which he concluded that both parties were really agreed on the essential point—that Homer was one of the greatest geniuses the world had seen, and that, as a whole, no other poem could be preferred to his; and, soon after (on the 4th of April 1716), in the house of M. de Valincourt, Mme Dacier and la Motte met at supper, and drank together to the health of Homer. Nothing of importance marks the rest of Mme Dacier's life. She died at the Louvre, on the 17th of August 1720.

DACITE (from Dacica, modern Transylvania), in petrology, volcanic rocks which may be considered a quartz-bearing variety of andesite. Like the latter they consist for the most part of plagioclase felspar with biotite, hornblende, augite or enstatite, and have generally a porphyritic structure, but they contain also quartz as rounded, corroded phenocrysts, or as an element of the ground-mass. Their felspar ranges from oligoclase to andesite and labradorite, and is often very zonal; sanidine occurs also in some dacites, and when abundant gives rise to rocks which form transitions to the rhyolites. The biotite is brown; the hornblende brown or greenish brown; the augite generally green. The ground-mass of these rocks is often microcrystalline, with a web of minute felspars mixed with interstitial grains of quartz; but in many dacites it is largely vitreous, while in others it is felsitic or cryptocrystalline. In the hand specimen many of the hornblende and biotite dacies are grey or pale brown and yellow rocks with white felspars, and black crystals of biotite and hornblende. Other dacies, especially augite- and enstatite-dacies, are darker coloured. The rocks of this group occur in Hungary, Almeria (Spain), Argyllshire and other parts of Scotland, New Zealand, the Andes, Martinique, New Guinea. The latter districts were mostly North and South R. &c. They are mostly associated with anidesites and trachytes, and form lava flows, dikes, and in some cases massive intrusions in the centres of old volcanoes. Among continental petrographers the older dacies (Carboniferous, &c.) are often known as "porphyrites."

(J. S. F.)

DACOIT, a term used in India for a robber belonging to an armed gang. The word is derived from the Hindustani dakoit, and being current in Bengal got into the Indian penal code. By law, to constitute dacoity, there must be five or more in the gang committing the crime. In the time of the Thugs (q. v.) a special police department was created in India to deal with thuggery and dacoity (thagi and dakoiti), which exists down to the present day. In Burma also the word dacoit came to be applied in a special sense to the armed gangs, which maintained a state of guerilla warfare for several years after the defeat of the king and his army. (See Burmese Wars.)

DA COSTA, ISAAC (1758-1860), Dutch poet and theologian, was born at Amsterdam on the 14th of January 1758. His father was a Jew oforthodox, and claimed kinship with the celebrated Uriel D'Acosta. An early acquaintance with Bilderdijk had a strong influence over the boy both in poetry and in theology. He studied at Amsterdam, and afterwards at Leiden, where he took his doctor's degree in law in 1816, and in literature in 1821. In 1814 he wrote De Verlossing van Nederland, a patriotic poem, which placed him in line with the contemporary national romantic poets in Germany and in France. His Poëzy (2 vols., 1821-1822) revealed his emancipation from the Bilderdijk tradition, and the oriental colouring of his poems, his hymn to Lamartine, and his translation of part of Byron's Cain, establish his claim to be considered as the earliest of the Dutch romantic poets. In 1822 he became a convert to Christianity, and immediately afterwards asserted himself as a champion of orthodoxy and an assailant of latitudinarianism in his Bewaarren tegen den Geest der Eeuw (1823). He took a lively interest in missions to the Jews, and towards the close of his life was a director of the seminary established in Amsterdam in connexion with the mission of the Free Church of Scotland. He died at Amsterdam on the 28th of April 1836. Da Costa ranked first among a group of Holland Hebrew scholars of the day. His principal poetic works were: Alphonsus I. (1818), a tragedy; Poëzy (Leiden, 1821); God metens (1826); Festiedern (1828); Vijf-en-twintig jaren (1840); Hagar (1852); De Slag bij Nieuwpoort (1857). He also translated The Persians (1816) and the Prometheus (1818) of Aeschylus, and edited the poetical works of Bilderdijk in sixteen volumes, the last volume being an account of the poet. He was the author of a number of theological works, chiefly in connexion with the criticism of the gospels.

His complete poetical works were edited by J. P. Hasebroek (3 vols., Haarlem, 1861-1862). See G. Groen van Prinsterer, Brieven van Mr T. i. da Costa, 1830-1850 (1872), and J. ten Brink, Geschiedenis der Noord-Nederlandsche Letteren in de 19e Eeuw (vol. I., 1888), which contains a complete bibliography of his works.

DACTYL (from Gr. ἀκρωτής, a finger), in prosody, a long syllable followed by two short. See Epic.

DAEDELUS, a mythical Greek architect and sculptor, who figures largely in the early legends of Crete and of Athens. He was said to have built the labryinth for Minos, to have made a wooden cow for Pasiphae and to have fashioned a bronze man who repelled the Argonauts. Falling under the displeasure of Minos, he fashioned wings for himself and his son Icarus, and escaped to Sicily. These legends seem primarily to belong to Crete; and the Athenian element in them which connected Daedalus with the royal house of Erechtheus is a later fabrication. To Daedalus the Greeks of the historic age were in the habit of attributing buildings, and statues the origin of which was lost in the past, and which had no inscription belonging to them. In a later verse in the Iliad (date, 7th or 6th century), Daedalus is mentioned as the maker of a dancing-place for Ariadne in Crete; and such a dancing-place has been discovered by A. J. Evans, in the Minoan palace of Cnossus. Diodorus Siculus says that he executed various works in Sicily for King Cocalus. In many cities of Greece there were rude wooden statues, said to be by him. Later critics, judging from their position of the time, the course of development in art, ascribed to Daedalus such improvements as separating the legs of statues and opening their eyes. In fact the name Daedalus is a mere symbol, standing for a particular phase of early Greek art, when wood was the chief material, and other substances were let into it for variety.

This Daedalus must not be confused with Daedalus of Sicyon, a great sculptor of the early part of the 4th century B.C., none of whose works is extant.

(P. G.)

DAIFFODIL, the common name of a group of plants of the genus Narcissus, and natural order Amaryllidaceae. (See generally under Narcissus.) The common daffodil, N. Pseudo-narcissus, is common in woods and thickets in most parts of the N. of Europe, but is rare in Scotland. Its leaves are five or six in number, are about a foot in length and an inch in breadth, and have a blunt keel and flat edges. The stem is about 18 in. long, and the spathe single-flowered. The flowers are large, yellow, scented and a little drooping, with a corolla deeply cleft into six lobes, and a central bell-shaped nectary, which is crisped at the base. They appear early in the year, or, as Shakespeare says, "earlier before March than the swallow dared to come, or March with beauty." The stamens are shorter than the cup, the anthers oblong and converging; the ovary is globose, and has three furrows; the seeds are roundish and black. Many new varieties of the flower have recently been cultivated in gardens. The bulbs are large and orbicular, and have a blackish coat; they, as well as the flowers, are reputed to be emetic in properties. The Peruvian daffodil and the sea daffodil are species of the genus Ismene. (For derivation see ASHODEL.)

DAFYDD AB GWILYM (c. 1340-c. 1400), son of Gwilym Gwyndd and Ardulf Fychain, greatest of the medieval Welsh poets, was born at Bro Gynin, Cardiganshire, about the year 1340. Educated by a scholarly uncle, Llewyn ab Gwilym Fychain of Emlyn, he became steward to his kinsman, Ivor Hael of Maesagel, Monmouthshire, who also appointed him instructor to his daughter. The latter arrangement leading to an attachment between tutor and pupil, the girl was banished to a convent in Anglesey, whither the poet followed her, taking service in an adjacent monastery, but on returning to Maesagel he was permitted to retain his stewardship, and he elected chief bard of Glamorgan and became household bard to Ivor Hael. At Rhosyr in North Wales he met Morphudd Lawgan, to whom he addressed 147 amatory odes. In consequence of attempting to elope with this lady, Dafydd ab Gwilym, being unable to pay the fine demanded by her husband, was imprisoned. Liberated by the goodwill of his friends, he went back to Maesagel, and after the death of his patron, retired to his birthplace, Bro Gynin.
Tradition states that he was a man of noble appearance, and his poems bear evidence of high mental culture. He was acquainted with the works of Homer, Virgil, Ovid and Horace, and was also a student of Italian literature. Especially remarkable as a poet of nature in an age when more were facile themes were chosen by his contemporaries, his poems entitled "The Lark," "The Wind" and "The Mist" are amongst his finest efforts. He has been called the Petrachr, the Ovid, and (by George Borrow) the Horace of Wales. His poems were almost all written in the cwydd form: a short ode not divided into stanzas, each line having the same number of syllables. The poet died about the year 1400, and according to tradition was buried in the graveyard of the monastery of Strata Florida, in Cardiganshire.

See also under Celt; Celtic Literature, iv. Welsh.

DAGGER, a hand weapon with a short blade. The derivation is obscure (cf. Fr. dague and Ger. Degen), but the word is related to dag, a long pointed jag such as would be made in deeply nicking the edge of a garment. The war knife in various forms and under many names has of course been in use in all ages and amongst all races. But the dagger as generally understood was not a short sword, but a special stabbing weapon which could be used along with the sword. The distinction is often difficult to establish in a given case owing to the variations in the length of the weapon. The principal medieval dagger was the misericorde, which from the end of the 12th century was used, in all countries in which chivalry flourished, to penetrate the joints of the armor of an unhorsed adversary (hence Ger. Panzerbrecher, armour-breaker). It was so called either because the threat of it was so great that it caused the vanquished to surrender "at mercy" or from its use in giving what was called the coup de grace. From about 1330 till the end of the succeeding century, in many knightly effigies it is often represented as attached on the right side by a cord or a chain to the sword-belt. This weapon and its sheath were generally elaborately adorned. It was customary to secure it from accidental loss by a guard-chain fastened to the breast-armour. Occasionally the misericorde was fixed to the body-armour by a staple; or, more rarely, it was connected with a gynetere or pouch. The misericorde may be called a poniard. The distinction between the dagger and the poniard is arbitrary, and in ordinary language the latter is taken as being the shorter and as having less resemblance to a short sword or cutlass. A weapon, with a longer blade than the misericorde, was habitually worn by civilians, including judges, during the middle ages; such weapons bore the name of anlance (from annulus, as it was fastened by a ring), bastardore langue de bœuf, the last from the broad ox-tongue shape of the blade. This had often a small knife fixed on the scabbard, like a Highland officer's dirk of the present day. By nobles and knights the dagger or poniard was worn when they had exchanged their armour for the costume of peace. It is recorded besides that when they appeared at a tournament and on some other occasions, ladies at that time wore daggers depending, with their gypciere, from their girdles. Thus, writing of the year 1548, Knighton speaks of certain ladies who were present at jousts as "habentes cutelos, quos dagгерiis vulgariter dicitur, in pochiis desuper impositis." A longer and heavier dagger with a broad blade (Italian) is called cinquegra.

The Scottish "dirk" was a long dagger, and survives in name in the dirk worn by midshipmen of the royal navy, and in fact in that worn by officers of Highland regiments. In the 17th and 18th centuries the infantry soldier (Swiss or lansknecht) carried a heavy poniard or dagger. This and the earlier Spanish dagger with a thumb-ring were distinctively the weapons of professional soldiers. The rise of duelling produced another type, called the main gauche, which was a parrying weapon and often had a toothed edge on which the adversary's sword was caught and broken. One form of this dagger had a blade which expanded into a triple fork on pressing a spring; this served the same purpose. The satellites of the Vehmgertsch had a similar weapon, in order, it is suggested, that their acts should be done in the name of the Trinity. The smaller poniards are generally called "stiletos." Much ingenuity and skill have been lavished on the adornment of daggers, and in rendering the blades more capable of inflicting severe wounds. Daggers also were sometimes made to poison as well as to wound. Of oriental daggers may be mentioned the Malay "crease" or "kris," which was a long waxed blade; the Gurka "kukri," a short curved knife, broadest and heaviest towards the point; and the Hindu "khatta," which has a flat triangular-shaped blade, and a hilt of H-shape, the cross-bar forming the grip and the sides the guard.

DAGHESTAN, a province of Russia, Transcaucasia, occupying the triangular space between the Andi ridge, the south-east division of the main Caucasus range, and the Caspian Sea. It has the province of Terek on the N.W., the government of Tiflis on the S.W., and that of Baku on the S.E. With the exception of a narrow strip along the sea-coast and a small district in the N., it is entirely mountainous. Area, 11,332 sq. m. The snow-clad Andi ridge, belonging to the system of transverse upheavals which cross the Caucasus, branches off the latter at Borbolo Peak (10,175 ft.), and reaches its highest altitudes in Tebulosma (14,775 ft.) and Diklosma (13,740 ft.). It is incised on the N. by a lower outer ridge, the Karadagh, through which the rivers cut their way. This ridge is the Andi ridge in the Andi province. The Andi and another ridge run between the four Koisu rivers, the head-streams of the Sulak, which flows into the Caspian. The next most important stream, out of the great number which course down the flanks of the Caucasus and terminate in the Caspian, is the Samor. The most notable feature of the province is, however, according to O. W. H. Abich (Sur la structure et la géologie du Daghestan, 1862), the successive folds of Jurassic limestones and slates, all nearly parallel to the Caucasus, which form lofty, narrow plateaus. Many of the peaks upon them rise higher than 12,000 ft., and the passes lie at altitudes of 11,000 ft. in the interior and 9000 ft. towards the Caspian. Towards the Caspian, especially between Petrovsk and the river Sulak, the Cretaceous system is well represented, and upon its rocks rest marls, shales, and sandstones of the Eocene period. The country is altogether difficult of access, and only one military route leads up from the river Terek, while every one of the eleven passes known across the Caucasus is a mere bridle-path. The climate is severe on the plateaus, hot towards the Caspian, and dry everywhere. The average temperatures are—year 5°, January 26°, July 73° at Temir-khan-shura (42° 49' N.; alt. 1350 ft.). The annual rainfall varies from 17 to 21 in. The population, estimated at 605,100 in 1906, numbered 587,326 in 1897, of whom only 5000 were Russians. They consist chiefly of mountaineers known as Lesghians (i.e. 158,550 Avars, 121,375 Darghis, 94,506 Kurins), a race closely akin to the Circassians, intermingled towards the Caspian Sea with Tatars and Georgians. There are also sprinklings of Jews and Persians. The highlands of Daghestan were for many years the stronghold of the Circassians in their struggle against Russia, especially under the leadership of Shamyl, whose last stand was made on the steep mountain fastness of Gunib, 74 m. S. of Temir-khan-shura, in 1859. The difficulty of communication between the valleys has resulted in the growth of a great number of dialects. Avarian is a sort of inter-tribal tongue, while Lakh or Kazi-kumukh, Kurin, Darghi-kaitakh, Andi, and Tabasar are some of the more important dialects, each subdivided into sub-dialects. The mountaineers breed some cattle and sheep, and fallow all sorts of crops on the mountain-sides. In the littoral districts excellent crops of cereals, cotton, fruit, wine and tobacco are obtained with the aid of irrigation. Silkworms are bred. The mountaineers excel as well as a variety of petty trades. Sulphur, salt and copper are the most important of the minerals. A railway line connects the North Caucasian line (Rostov to Petrovsk) with the Transcaucasian line (Batum to Baku) has been built along the Caspian shore from Petrovsk, through the "gate" or pass of Derbent, to Baku. The province is divided into nine districts—Temir-khan-shura, Avar, Andi, Gunib, Dargo, Kazi-kumukh, Kaitago-Tabasar, Kurin, and Samur. The only towns are Temir-khan-shura (pop. 9208 in 1897), the capital of the government, Derbent (14,821) and Petrovsk (9806), the last two both on the Caspian.
DAGO—DAGUERRE

DAGO, a name given somewhat contemptuously to Spanish, Portuguese and Italian sailors, as "Dutchman," is similarly applied to Germans and Scandinavians as well as to natives of Holland. In America the word is generally confined to the poorer classes. H. L. Hargrove, J. F. Varela, Diego, and the cabal labourers, who are only engaged when work is plentiful, are so called. The word is apparently a corruption of the common Spanish and Portuguese Christian name "Diego."

DAGOBERT I. (d. 639), king of the Franks, was the son of Clotaire II. In 623 his father established him as king of the region east of the Ardenne, and in 626 revived for him the ancient kingdom of Austrasia, minus Aquitaine and Provence. As Dagobert was yet but a child, he was placed under the authority of the mayor of the palace, Pippin, and Arnulf, bishop of Metz. At the death of Clotaire II. in 629, Dagobert wished to re-establish unity in the Frankish realm, and in 629 and 630 made expeditions into Neustria and Burgundy, where he succeeded in securing the recognition of his authority. In Aquitaine he gave his brother Charibert the administration of the counties of Toulouse, Cahors, Agen, Periguel, and Saintes; but at Charibert's death in 632 Dagobert became sole ruler of the whole of the Frankish territories south of the Loire. Under him the Merovingian monarchy attained its culminating point. He restored to the royal domain the lands that had been usurped by the great nobles and by the church; he maintained at Paris a luxurious, though, from the example he himself set, a disorderly court; he was a patron of the arts, and delighted in the splendid craftsmanship of his treasurer, the goldsmith St. Eloi. His authority was recognized through the length and breadth of the realm. The duke of the Basques came to his court to swear fidelity, and at his villa at Clichy the chief of the Bretons of Domnoné promised obedience. He intervened in the affairs of the Visigoths of Spain and the Lombards of Italy, and was heard with deference. Indeed, as a sovereign, Dagobert was reckoned superior to the other barbarian kings. He entered into relations with the eastern empire, and swore a "perpetual peace" with the emperor Heraclius; and it is probable that the two sovereigns took common measures against the Slav and Bulgarian tribes, which ravaged in turn the Byzantine state and the German territories subject to the Franks. Dagobert protected the church and placed illustrious prelates at the head of the bishops—Elui (Eligius) at Noyon, Ouen (Audoen) at Rouen, and Didier (Desiderius) at Cahors. His reign is also marked by the creation of numerous monasteries and by renewed missionary activity in Flanders and among the Basques. He died on the 10th of January 639, and was buried at St. Denis. After his death the Frankish monarchy was again divided. In 634 he had been obliged to give the Austrasian a special King in the person of his eldest son Sigebert, and at the birth of a second son, Chlothar in 635, the Neustrians had immediately claimed him as king. Thus the unification of the realm, which Dagobert had re-established with so much pains, was annulled.

DAGON, a god of the Philistines who had temples at Ashkelon (1 Sam. v. 1), and Gaza (Judg. xvi. 21, 23); the former was destroyed by Jonathan, the brother of Judas the Macabæus (1 Mac. x. 91; 148 C. B.).

Dagon was more than a mere local deity; there was a place called Beth-Dagon in Judah (Josh. xvii. 41), another on the borders of Asher (ib. xix. 27), and a third underlies the modern Bé Déjan, south-east of Nâbûs. Dagon was in all probability an old Canaanite deity; it appears in the name of the Canaanite Dagantakal as early as the 12th century, and is possibly to be identified with the Babylonian god Dagan. Little is known of his cult (Judg. xvi. 23 seq.), although he was the male counterpart of Ashreth (see ASTARTE) his worship would scarcely differ from that of the Baalim (see BAAL). The name Dagon seems to come from dâg "fish," and that his idol was half-man half-fish is possible from the ichthyomorphic representations found upon coins of Ascalon and Arvad, and from the fact that Berossus speaks of an Assyrian merman-god.

The true meaning of the name is doubtful. In 1 Sam. v. 4, Thelnou and Whilhebaum, followed by Robertson Smith and others, read only his fish-part (dâg) was left to him; against this, see the conjecture of A. Neumayer: "The name Dagon with the Babylonian Dagan is doubted by G. F. Moore (Enzyk. Bib. col. 985), and that of the latter with Odonca and Ea-Oannes is questionable. Philip Byblius (Miller, Flr. Hist. Grac. iii. 567 seq.) makes Dagon the inventor of corn and the plough, whence he was called the god of the earth." However, the unlikelihood of a later etymology from the Hebrew and Phoenician dagan "corn." It is not improbable that, at least in later times, Dagon had in place of, or in addition to, his old character, that of the god who presided over the fertility of the land, and in this character appears with particular mention especially by women, may perhaps be connected with the threshold on which the priests of Dagon would not touch with their feet (1 Sam. v. 1, Zeph. i. 9). See further, the comm. on the Old Testament passages before referred to.

DAGUERRE, LOUIS JACQUES MANDÉ (1787–1851), French painter and physiologist, inventor of the daguerreotype, was born at Corrèze, in the department of Seine-et-Oise, and died on the 12th of July 1851 at Petit-Brie-sur-Marne, near Paris. He was at first occupied as an inland revenue officer, but soon took to scene-painting for the opera. He assisted Pierre Prévost (1764–1823) in the execution of panoramic views of Rome, Naples, London, Jerusalem, and Athens, and subsequently (July 11, 1822), in conjunction with Bouton, he opened at Paris the Diorama (88 ft. double; opeяна, view), an exhibition of pictorial views, the effect of which was heightened by changes in the light thrown upon them. An establishment similar to that at Paris was opened by Daguerre in Regent's Park, London. On the 3rd of March 1839 the Diorama, together with the work on which Daguerre was then engaged, was destroyed by fire. This reverse of fortune was soon, however, more than compensated for by the distinction he achieved as the inventor of the daguerreotype photographic process. J. Nicéphore Niepce, who since 1814 had been seeking without success permanent pictures by the action of sunlight, learned in 1826 that Daguerre was engaged in a similar occupation. In 1839 he communicated to Daguerre particulars of his method of fixing the images produced in the camera lucida by making use of metallic plates coated with a composition of asphalt and oil of lavender; this, where acted on by the light, remained undissolved when the plate was plunged into a mixture of petroleum and oil of lavender, and the development of the image was effected by the action of acids and other chemical reagents on the exposed surface of the plate. The two inventors laboured together in the production of their "heliographic pictures" from 1829 until the death of Niepce in 1833. Daguerre, continuing his experiments, discovered eventually the process connected with his name. This, as he described it, consists of five operations:—the polishing of the silver plate; the coating of the plate with iodide of silver by submerging it for about 20 minutes to the action of iodine vapour; the projection of the image of the object upon the golden-coloured iodized surface; the development of the latent image by means of the vapour of mercury; and, lastly, the fixing of the picture by immersing the plate in a solution of sodium thiosulphate (sodium thiosulphate). On the 9th of January 1839, at a meeting of the Academy of Sciences, Arago dwelt on the importance of the discovery of the daguerreotype; and, in consequence of the representations made by him and Gay Lussac to the French government, Daguerre was on the 15th of June appointed an officer of the Legion of Honour. On the same day a bill was presented to the chambers, according to which
Daguerre and the heir of Niepce were to receive annuities of 6000 and 4000 francs respectively, on the condition that their process should be made known to the Academy. The bill having been approved at the meetings of the two chambers on the 9th of July and on the 1st of August, Daguerre's process, together with his eyes of transparent and opaque painting, was published by the government, and soon became generally known (see Photography).

Daguerre's Historique et description des procédés du daguerréotype et du diorama (Paris, 1839) passed through several editions, and was translated into English. Beside this he wrote an octavo work, intitule Nouveau moyen de préparer la couche sensible des plaques destinées à recevoir les images photographiques (Paris, 1844).

DAGUPAN, a town and the most important commercial centre of the province of Pangasinán, Luzon, Philippine Islands, on a branch of the Agno river near its entrance into the Gulf of Lingayen, 120 m. by rail N.N.W. of Manila. Pop. (1900), 20,357.

It is served by the Manila & Dagupan railway. Dagupan has a healthy climate. It is the chief point of exportation for a very rich province, which produces sugar, indigo, Indian corn, copra, and especially rice. There are several rice mills here. Salt is an important export, being manufactured in salt water swamps and marshes throughout the province of Pangasinán (whose name, from asin, "salt," means the place where salt is produced). In these marshes grows the fresh water pala from which a liquor is distilled, and a number of still distilleries here. Dagupan has a small shipyard in which sailing vessels and steam launches are constructed. The principal language is Pangasinán.

DAHABEAH (also spelt dahabiba, dahabil, dahabeyyah, &c.), an Arabic word (variously derived from dahab, gold, and dahab, one of the forms of the verb to go) for a native passenger boat used on the Nile. The typical form is that of a barge-like house-boat provided with sails, resembling the painted galleys represented on the tombs of the Pharaohs. Similar state barges were used by the Mahammedan rulers of Egypt, and from the circumstance that these vessels were ornamented with gilding is attributed the usual derivation of the name from gold. Before the introduction of steamers dahabees were generally used by travellers ascending the Nile, and they are still the favourite means of travelling for the leisureed and wealthy classes. The modern dahabee is often made of iron, draws about 2 ft. of water, and is provided with one very large and one small sail. According to size it provides accommodation for from two to a dozen passengers. Steam dahabees are also built to meet the requirements of tourists.

DAHL, HANS (1849— ), Norwegian painter, was born at Hardanger. After being in the Swedish army he studied art at Karlsruhe and at Düsseldorf, being a notable painter of landscape and genre. His work has considerable humour, but his colouring is hard and rather crude. In 1889 he settled in Berlin. His pictures are very popular in Norway.

DAHL, JOHANN CHRISTIAN (1775—1837), Norwegian landscape painter, was born in Bergen. He formed his style without much tuition, remaining at Bergen till he was twenty-four, when he left for the better field of Copenhagen, and ultimately settled in Dresden in 1818. He is usually included in the German school, although he was thus close on forty years of age when he finally took up his abode in Dresden, where he was quickly received into the Academy and became professor. German landscape-painting was not greatly advanced at that time, and Dahl contributed to improve it. He continued to reside in Dresden, though he travelled into Tirol and in Italy, painting many pictures, one of his best being that of the "Watteberg of Venvius, 1820." He was a master of extraordinary effects, as seen in his "Winter at Munich," and his "Dresden by Moonlight," also the "Haven of Copenhagen," and the "Schloss of Friederichsburg," under the same condition. At Dresden may be seen many of his works, notably a large picture called "Norway," and a "Storm at Sea." He was received into several academic bodies, and had the orders of Wasa and St Olaf sent him by the king of Norway and Sweden.

DAHL, MICHAEL (1656—1743), Swedish portrait painter, was born at Stockholm. He received his first professional education from Ernst Klocke, who had a respectable position in that northern town, which, however, Dahl left in his twenty-second year. His first destination was England, where he did not long remain, but crossed over to Paris, and made his way at last to Rome, there taking up his abode for a considerable time, painting the portraits of Queen Christina and other celebrities. In 1688 he returned to England, and became for some years a dangerous rival to Kneller. He died in London. His portraits still exist in many houses, but his name is not always preserved with them. Nagler (Künstler-Lexicon) says those at Hampton Court and at Petworth contest the palm with those of the better known and vastly more employed painter.

DAHL (or DALE), VLADIMIR IVANOVICH (1862—1872), Russian author and philologist, was born of Scandinavian parentage in 1802, and received his education at the naval cadets' institution at St Petersburg. He joined the Black Sea fleet in 1819; but at a later date he entered the military service, and was thus engaged in the Polish campaign of 1831, and in the expedition against Khiva. He was afterwards appointed to a medical post in one of the government hospitals at St Petersburg, and was ultimately transferred to a situation in the civil service. The latter years of his life were spent at Mossov, and he died there on November 22, 1872. Under the name of Kossack Lugansky he obtained considerable fame by his stories of Russian life—The Dream and the Waking, A Story of Misery, Happiness, and Truth, The Door-Keeper (Dverniki), The Officer's Valet (Denakhck). His greatest work, however, was a Dictionary of the Living Russian Tongue (Tolkovy Slavar Zhivago Velkorusskago Yasika), which appeared in four volumes between 1861 and 1866, and is of the most essential service to the student of the popular literature and folk-lore of Russia. It was based on the results of his own investigations throughout the various provinces of Russia—investigations which had furnished him with no fewer than 4000 popular tales and upwards of 30,000 proverbs. Among his other publications may be mentioned Bemerkungen zu Zimmermann's Entwurf des Kriegshistor. Russlands gegen Khiva, published in German at Orenburg, and a Handbook of Botany (Moscow, 1849).

A collected edition of his works appeared at St Petersburg in 8 volumes, 1860—1861.

Dahlberg (Dahlbergh), ERIK JOHANSEN, COUNT (1625—1703), Swedish soldier and engineer, was born at Stockholm. His early studies took the direction of the science of fortification, and as an engineer officer he saw service in the latter years of the Thirty Years' War, and in Poland. As adjutant-general and engineer adviser to Charles X. (Gustavus), he had a great share in the famous crossing of the frozen Belts, and at the sieges of Copenhagen and Kronborg he directed the engineers. In spite of these distinguished services, Dahlberg remained an obscure lieutenant-colonel for many years. His patriotism, however, proved superior to the tempting offers Charles II. of England made to induce him to enter the British service, though, in that age of professional soldiering, there was nothing in the offer that a man of honour could not accept. At last his talents were recognized, and in 1676 he became director-general of fortifications. In the wars of the next twenty-five years Dahlberg again rendered distinguished service, alike in attack (as at Helsingborg in 1677, and Dänemünde in 1700) and defence (as in the two sieges of Riga in 1700); and his work in repairing the fortresses of his own country, not less important, earned for him the title of the Virtuous of Sweden. He was also the founder of the Swedish engineer corps. He retired as field-marshal in 1702, and died the following year.

Erik Dahlberg was responsible for the fine collection of drawings called Svea antiqua et hodierna (Stockholm, 1660—1716; 2nd edition, 1836; 3rd edition, 1864—1865), and assisted Pufendorf in his Histoire de Charles X Gustave. He wrote a memoir of his life (to be found in Svenska Bibliotek, 1757) and an account of the campaigns of Charles X. (ed. Lundblad, Stockholm, 1823).

DAHLGREN, JOHN ADOLF (1809—1879), admiral in the U.S. navy, was the son of the Swedish consul at Philadelphia, Pennsyl-
DAHLGREN, K. F.—DAHLMANN

DAHLGREN, KARL FREDRIK (1791–1844), Swedish poet, was born at Stens bruk in Östergötland on the 20th of June 1791. At a time when literary partisanship ran high in Sweden, and the writers divided themselves into "Goths" and "Phosphorists," Dahlgren made himself indispensable to the Phosphorists by his poetical activity. In the mock-heroic poem of Markall's Simlados Nätter (Markall's Sleepless Nights), in which the Phosphorists ridiculed the academicians Per Adam Wallmark and others, Dahlgren, who was a genuine humorist, took a prominent part. In 1825 he published Babels Torn (The Tower of Babel), a satire, and a comedy, Argus in Olympe; and in 1828 two volumes of poems. In 1820 he was appointed to an ecclesiastical post in Stockholm, which he held until his death. In a series of odes and dihyrambic pieces, entitled Mollarps Episolar (1819, 1820), he strove to emulate the wonderful lyric genius of K. M. Bellman, of whom he was a student and follower. From 1825 to 1827 he edited a critical journal entitled Kometen (The Comet), and in company with Almqvist he founded the Manhems-förbund, a short-lived society of agricultural socialists. In 1834 he collected his poems in one volume; and in 1837 appeared his last book, Angelis-Singer (Steamboat Songs). On the 1st of May 1844 he died at Stockholm. Dahlgren is one of the best humorists Sweden has produced; but he was perhaps at his best in realistic and idyllic description. His little poem of Zephyr and the Girl, which is to be found in every selection from Swedish poetry, is a good example of his sensuous and ornamented style.

His works were collected and published after his death by A. J. Arwidsson (5 vols., Stockholm, 1847–1852).

DAHLIA, a genus of herbaceous plants of the natural order Composite, so called after Dr Dahl, a pupil of Linnaeus. The genus contains about nine species indigenous in the high sandy plains of Mexico. The dahlia was first introduced into Britain from Spain in 1798 by the marchioness of Buté. The species was probably D. variabilis, whence by far the majority of the forms now common have originated. The flowers, at the time of the first introduction of the plant, were single, with a yellow disk and dull scarlet rays; under cultivation since the beginning of the 19th century in France and England, flowers of numerous brilliant hues have been produced. The flower has been modified also from a flat to a globular shape, and the arrangement of the florets has been rendered quite distinct in the ranunculus and anemone-like kinds. The ordinary natural height of the dahlia is about 7 or 8 ft., but one of the dwarf races grows to only 18 in. With changes in the flower, changes in the shape of the seed have been brought about by cultivation; varieties of the plant have been produced which require more moisture than others; and the period of flowering has been made considerably earlier. In 1808 dahlias were described as flowering from September to November, but some of the dwarf varieties at present grown are in full blossom in the middle of June.

The large number of varieties may be classed as under the following heads: (1) Single dahlias. These have been derived from D. coccineas; they have a disk of tubular florets surrounded by the large showy ray florets. (2) Show dahlias, large and double with flowers self-coloured or pale-coloured and edged or tipped with a darker colour. (3) Fancy dahlias, resembling the show but having the florets striped or tipped with a second tint. (4) Bouquets or Pompon dahlias, with much smaller double flowers of various colours. (5) Cactus dahlias, derived from D. Jalmenus, a form which has given rise to a beautiful race with pointed starry flowers. (6) Paeony-flowered dahlias, a new but not pretty race, with large floppy heads, broad florets and several disk florets in centre.

New varieties are procured from seed, which should be sown in pots or pans towards the end of March, and placed in a hotbed or propagating pit, the young plants being pricked off into pots or boxes, and gradually hardened off for planting out in June; they will flower the same season if the summer is a genial one. The older varieties are propagated by dividing the large tuberous roots, in doing which care must be taken to leave an eye to each portion of tuber, otherwise it will not grow. Rare varieties are sometimes grafted on the roots of others. The best and most general mode of propagation is by cuttings, to obtain which, the old tubers are placed in heat in February, and as the young shoots, which rise freely from them, attain the height of 3 in., they are taken off with a heel, and planted singly in small pots filled with finely sandy soil, and plunged in a moderate heat. They root speedily, and are then transferred to larger pots in light rich soil, and their growth encouraged until the planting-out season arrives, about the middle of June north of the Thames.

Dahlias succeed best in an open situation, and in rich deep loam, but there is scarcely any garden soil in which they will not thrive, if it is manured. For the production of fine show flowers the ground must be deeply trenched, and well manured annually. The branches as well as the blooms require a considerable but judicious amount of thinning; they also need shading in some cases. The plants should be protected from cold winds, and when watered the whole of the foliage should be wetted. They may stand singly like common border flowers, but have the most imposing appearance when seen in masses arranged according to their height. Florists usually devote a plot of ground to them, and plant them in I. M. 5 to 10 ft. apart. This is done about the beginning of June, sheltering them if necessary from frosts by inverted pots or in some other convenient way. Old roots often throw up a multitude of stems, which render thinning necessary. As the plants increase in height, they are furnished with strong stakes, to secure them from high winds. Dahlias flower on till they are interrupted by frost in autumn. The roots are then taken up, dried, and stored in a cellar, or some other place where they may be secure from frost and moisture. Earwigs are very destructive, eating out the young buds and florets. Small flower-pots half filled with dry moss and inverted on stakes placed among the branches, form a useful trap.

DAHLMANN, FRIEDRICH CHRISTOPH (1785–1860), German historian and politician, was born on the 13th of May 1785; he came of an old Hanseatic family of Wismar, which then belonged to Sweden. His father, who was the burgomaster of the town, intended him to study theology, but his bent was towards classical philology, and this he studied from 1802 to 1806 at the universities of Copenhagen and Halle, and again at Copenhagen. After finishing his studies, he translated some of the Greek tragic poets, and the Clouds of Aristophanes. But he
Dahlstjerna was also interested in modern literature and philosophy; and the troubles of the times, of which he had personal experience, aroused in him, as in so many of his contemporaries, a strong feeling of German patriotism, though throughout his life he was always proud of his connexion with Scandinavia, and Gustavus Adolphus was his particular hero. In 1809, on the news of the outbreak of war in Austria, Dahlmann, together with the poet Heinrich von Kleist, whom he had met in Dresden, went to Bohemia, and was afterwards with the Imperial army, up till the battle of Aspern, with the somewhat vague object of trying to convert the Austrian war into a German one. This hope was shattered by the defeat of Wagram. He now decided to try his fortunes in Denmark, where he had influential relations. After taking his doctor's degree at Wittenberg (1810) he qualified at Copenhagen in 1811, with an essay on the origins of the ancient theatre, an interesting treatise on ancient literature and history, on which he delivered lectures in Latin. His influential friends soon brought him further advancement. As early as 1812 he was summoned to Kiel, as successor to the historian Dietrich Hermann Hegewisch (1746–1812). This appointment was in two respects a decisive moment in his career; on the one hand it made him give his whole attention to a subject for which he was admirably suited, to which he had so far given only a secondary interest; and on the other, it threw him into politics.

In 1815 he obtained, in addition to his professorate, the position of secretary to the perpetual deputation of the estates of Schleswig-Holstein. In this capacity he began, by means of memoirs or of articles in the Kieler Blätter, which he founded himself, to appear as an able and zealous champion of the half-forgotten rights of the Elbe duchies, as against Denmark, and of their close connexion with Germany. It was he upon whom the Danes afterwards threw the blame of having invented the Schleswig-Holstein question; certainly his activities form an important link in the chain of events which eventually led to the solution of 1864. So far as this interest affected himself, the chief profit lay in the fact that it deepened his conception of the state, and directed it to more practical ends. Whereas at that time mere speculation dominated both the French Liberalism of the school of Rotteck, and Karl Ludwig von Haller's Romanticist doctrine of the Christian state, Dahlmann took as his premises the circumstances as he found them, and evolved the new out of the old by a quiet process of development. Inevitable consequences followed: the Danish crown his upright point of view and his German patriotism were further confirmed. After his transference to Göttingen in 1829 he had the opportunity of working in the same spirit. As confidant of the duke of Cambridge, he was allowed to take a share in framing the Hanoverian constitution of 1833, which remodelled the old aristocratic government in a direction which had become inevitable since the July revolution in Paris; and when in 1837 the new king Ernest Augustus declared the constitution invalid, it was Dahlmann who inspired the famous protest of the seven professors of Göttingen. He was deprived of his position and banished, but he had the satisfaction of knowing that German national feeling received a mighty impulse from his courageous action, while public subscriptions prevented him from material cares.

After he had lived for several years in Leipzig and Jena, King Frederick William IV. appointed him in October 1842 to a professorship at Bonn. The years that followed were those of his highest celebrity. His Politik (1835) had already made him a great name as a writer; he now published his Dänische Geschichte (1840–1843), a historical work of the first rank; and this was soon followed by histories of the English and French revolutions, which, though of less scientific value, exercised a decisive influence upon public opinion by their open advocacy of the system of constitutional monarchy. As a teacher too he was much beloved. Though no orator, and in spite of a personality not particularly amiable or winning, he produced a profound impression upon young men by the pregnancy of his expression, a consistent logical method of thought based on Kant and by the manliness of his character. When the revolution of 1848 broke out, the "father of German nationality," as the provisional government at Milan called him, found himself the centre of universal interest. Both Mecklenburg and Prussia offered him in vain the post of envoy to the diet of the confederation. Naturally, too, he was elected to the national assembly at Frankfort, and took a leading part in the constitutional committees appointed first by the diet, then by the parliament. His object was to make Germany as far as possible a united constitutional monarchy, with the exclusion of the whole of Austria, or at least, of its non-German parts. Prussia was to provide the emperor, but at the same time—and in this lay the doctrinaire weakness of the system—was to give up its separate existence, consecrated by history, in the same way as the other states. When, therefore, Frederick William IV., without showing any anxiety to bind himself by the conditions laid down at Frankfort, concluded with Denmark the seven months' truce of Malmö (26th August 1848), Dahlmann proposed that the national parliament should refuse to recognize the truce, with the express intention of clearing up once for all the relations of the parliament with the court of Berlin. The motion was passed by a small majority (September 5th); but the members of Dahlmann's party were just those who voted against it, and it was they who on the 17th of September reversed the previous vote and passed a resolution accepting the truce, after Dahlmann had failed to form a ministry on the basis of the resolution of the 5th, owing to his objection to the Radicals. Dahlmann afterwards described this as the decisive turning-point in the fate of the parliament. He did not, however, at once give up all hope. Though he took but little active part in parliamentary debates, he was very active on commissions and in party conferences, and it was largely owing to him that a German constitution was at last evolved, and that Frederick William IV. was elected hereditary emperor (28th of March 1849). He was accordingly one of the deputies which offered the crown to the king in Berlin. The king's refusal was less of a surprise to him than to most of his colleagues. He counted on being able to compel recognition of the constitution by the moral pressure of the consent of the people. It was only when the attitude of the Radicals made it clear to him that this course would lead to a revolution, that he decided, after a long struggle, to retire from the national parliament (21st May). He was still, however, one of the chief promoters of the well-known conference of the Lower Saxony party in Berlin, which prevailed, not, however, satisfactory to him; and he took part in the sessions of the first Prussian chamber (1849–1850) and of the parliament of Erfurt (1850). But finally, convinced that for the moment all efforts towards the unity of Germany were unavailing, he retired from political life, though often pressed to stand for election, and again took up his work of teaching at Bonn. His last years were, however, saddened by illness, bereavement and continual friction with his colleagues. His death took place on the 5th of December 1860, following on an apoplectic fit. He was a man whose personality had contributed to the progress of the world, and whose teaching was to continue to exercise a far-reaching influence on the development of German affairs.

His chief works were: Quellenkunde der deutschen Geschichte namentlich der Gegenwart (5 vols., 1830–1840); Dänisch-Danische, Politik, auf den Grund und das Mass der gegebenen Zustände zurückgeführt (1 vol., 1835); Geschichte Dänemarks (3 vols., 1840–1843); Geschichte der englischen Revolution (1844); Geschichte der französischen Revolution (1845).

See A. Springer, Friedrich Christoph Dahlmann (2 vols., 1870–1872); and H. v. Treitschke, Histor. und polit. Aufsätze, i. 365 et seq.

Dahlstjerna, Gunno (1661–1709), Swedish poet, whose original surname was Eurelius, was born on the 7th of September 1661 in the parish of Öhr in Dalsland, where his father was rector. He entered the university of Upsala in 1677, and after gaining his degree entered the government office of land-surveying. He was sent in 1681 on professional business to Livonia,
DAHN—DAHOMEY

then under Swedish rule. A dissertation read at Leipzig in 1867 brought him the offer of a professorial chair in the university, which he refused. Returning to Sweden he executed commissions in land-surveying directed by King Charles XI, and in 1699 he became head of the whole department. In 1702 he was ennobled under the name of Dahlstjerna. He wandered over the whole of the coast of the Baltic, Livonia, Rügen and Pomerania, preparing maps which still exist in the office of public land-surveying in Stockholm. His death, which took place in Pomerania on his forty-eighth birthday, 7th of September 1709, is said to have been hastened by the disastrous news of the battle of Pultava. Dahlstjerna's patriotism was touching in its pathos and intensity, and during his long periods of professional exile he comforted himself by the composition of songs to his beloved Sweden. His genius was most irregular, but at his best he easily surpasses all the Swedish poets of his time. His best-known original work is Kungskild (Stettin, 1697), an elegy on the death of Charles XI. It was written in alexandrine stanzas, and arranged in ottava rima. The poem is pompous and allegorical, but there are passages full of melody and high thoughts. Dahlstjerna was a reformer in language, and it has been well said by Atterbom that in this poem "he treats the Swedish speech just as dictatorially as Charles XI. and Charles XII. treated the Swedish nation." In 1690 was printed Stettin's paraphrase of the Pastor Fido of Guarini. His most popular work is his Gotta kampovisa om Konungen och Herr Peder (The Goth's Battle Song, concerning the King and Master Peter; Stockholm, 1701). The King is Charles XII. and Master Peter is the tsar of Russia. This spirited ballad lived almost until our own days on the lips of the people as a folk-song.

The works of Dahlstjerna have been collected by P. Hansell, in the series of histories and historical romances which has made his name a household word in Germany. The great history of the German migrations, Die König der Deutschen (Bände i.-vii. (Munich and Würzburg, 1861-1870), Bände vii.-xi. (Leipzig, 1894-1908), was a masterly study in constitutional history as well as a literary work of high merit, which carries the narrative down to the dissolution of the Carolingian empire. In his Übersicht der germanischen und romanischen Völker (Berlin, 1881-1890), Dahl went a step farther back still, but here as in his Geschichte der deutschen Urzeit (Gotha, 1883-1888), a wealth of picturesque detail has been worked over and resolved into history with such imaginative insight and critical skill as to make real and present the indistinct beginnings of German society. Together with these larger works Dahl wrote many monographs and studies upon primitive German society. Many of his essays were collected in a series of six volumes entitled Bauwesen (Berlin, 1879-1884). Not less important than his histories are the historical romances, the best-known of which, Ein Kampf um Rom, in four volumes (Leipzig, 1876), which has gone through many later editions, was also the first of the series. Others are Odhins Trost (Leipzig, 1880); Die Kreuzfahrer (Leipzig, 1884);

Odhins Rache (Leipzig, 1891); Juliana der Abtinnige (Leipzig, 1894), and one of the most popular, Bis zum Tode gereet (Leipzig, 1887). The list is too long to be given in full, yet almost all are well-known. Parallel with this great production of learned and imaginative works, Dahl published some twenty small volumes of poetry. The most notable of these are the epics of the early German period. His wife Therese, née Frein von Droste-Hülshoff, was joint-author with him of Walhall, Germanische Götter und Heldensagen (Leipzig, 1898).

A collected edition of his works of fiction, both in prose and verse, has reached twenty-one volumes (Leipzig, 1868), and a new edition was published in 1901. Dahl also published four volumes of memoirs, Erinnerungen (Leipzig, 1890-1895).

DAHOMEY (Fr. Dahomey), a country of West Africa, formerly an independent kingdom, now a French colony. Dahomey is bounded S. by the Gulf of Guinea, E. by Nigeria (British), N. and N.W. by the French possessions on the middle Niger, and W. by the German colony of Togoland. The French colony extends far north of the limits of the ancient kingdom of the same name. With a coast-line of only 75 m. (2° 38' E. to 2° 40' 55" E.), the area of the colony is about 40,000 sq. m., and the population over 1,000,000. As far as 6° N. the width of the colony is no greater than the coast-line. From this point, the colony broadens out both eastward and westward, attaining a maximum width of 200 m. It includes the western part of Borgu (g.v.), and reaches the Niger at a spot a little above Illo. Its greatest length N. to S. is 430 m.

Physical Features.—The littoral, part of the old Slave Coast (see Guinea), is very low, sandy and obstructed by a bar. Behind the seashore is a line of lagoons, where small steamers can ply; east to west they are those of Porto Novo (Lake Nokue), Whydah and Grand Popo. The Weme (300 m. long), known in its upper course as the Ofé, the most important river running south, drains the colony from the Bariba country to Porto Novo, entering the lagoon so named. The Zu is a western affluence, which, as the W. coast of the Zu west is the Kufu (150 m. long), which, before entering the Whydah lagoon, is dammed at a lake or lagoon called Ahémé, 20 m. long by 5 m. broad. The Makru and Kergigoto, each of which has various affluents, flow north-east to the Niger, which in the part of its course forming the north-east frontier of the colony is only navigable for small vessels and that with great difficulty (see Niger).

For some 50 m. inland the country is flat, and, after the first mile or two of sandy waste is passed, covered with dense vegetation. At this distance (50 m.) from the coast is a great swamp known as the Loma Marsh. It extends east to west some 25 m. and north to south 6 to 9 m. North of the swamp the land rises by regular stages to about 1650 ft., the high plateau falling again to the basin of the Niger. In the north-west a range of hills known as the Atacora forms a watershed between the basins of the Weme, the Niger and the Volta. A large part of the interior consists of undulating country, rather barren, with occasional woods. The forests contain the baobab, the cocom-coconut palm and the oil palm. The fauna resembles that of other parts of the West Coast, but the larger wild animals, such as the elephant and hippopotamus, are rare. The lion is found in the regions bordering the Niger. Some kinds of antelopes are common; the buffalo has disappeared.

Climate.—The climate of the coast regions is very hot and moist. Four seasons are well marked: the harmattan or long dry season, from the 1st December to the 15th March; the season of the great rains, from the 15th March to the 15th July; the short dry season, from the 15th July to the 15th September; and the "little rains," from the 15th September to the 1st December. Near the sea the average temperature is about 80° F. The harmattan prevails for several days in succession, and alternates with winds from the south and south-west. During its continuance the thermometer falls about 10°, there is not the slightest moisture in the atmosphere, vegetation dries up or droops, the skin parches and peels, and all woodwork is liable to warp and crack with a loud report. Tornadoes occur occasionally. During nine months of the year the climate is tempered by a sea-breeze, which is felt as far inland as Abomey.
DAHOMEY

(60 m.). It generally begins in the morning, and in the summer it often increases to a stiff gale at sundown. In the interior there are but two seasons: the dry season (November to May) and the rainy season (June to October). The rains are more scanty and diminish considerably in the northern regions.

Inhabitants.—The inhabitants of the coast region are of pure negro stock. The Dahomeyans (Dahomi), who inhabit the central part of the colony, form one of eighteen closely-allied clans occupying the country between the Volta and Porto Novo, and from their common tongue known as the Ewe-speaking tribes. In their own tongue Dahomeyans are called Fon or Fawin. They are tall and well-formed, proud, reserved in demeanour, polite in their intercourse with strangers, warlike and keen traders. The Mina, who occupy the district of the Popos, are noted for their skill as surf-men, which has gained for them the title of the Krumen of Dahomey. Porto Novo is inhabited by a tribe called Nago, which has an admixture of Yoruba blood and speaks a Yoruba dialect. The Nago are a peaceful tribe and even keener traders than the Dahomi. In Whydah and other coast towns are many mulattos, speaking Portuguese and bearing high-sounding Portuguese names. In the north the inhabitants—Mahi, Barlin, Gurmai—are also of Negro stock, but scarcely so civilized as the coast tribes. Settled among them are communities of Fula and Hausas. There are many converts to Islam in the northern districts, but the Mahi and Dahomeyans proper are nearly all fetish worshippers.

Chief Towns.—The chief port and the seat of government is Kotonu, the starting-point of a railway to the Niger. An iron pier, which extends well beyond the surf, affords facilities for shipping. Kotonu was originally a small village which served as the seaport of Porto Novo and was burnt to the ground in 1890. It has consequently the advantage of being a town laid out by Europeans on a definite plan. Situated on the beach between the sea and the lagoon of Porto Novo, the soil consists of heavy sand. Good hard roads have been made. Owing to an almost constant west wind and the shelter of the sea, Kotonu is in comparison with the other coast towns, decidedly healthy for white men. Porto Novo (pop. about 50,000), the former French headquarters and chief business centre, is on the northern side of the lagoon of the same name and 20 m. north-east of Kotonu by water. The town has had many names, and that by which it is known to Europeans was given by the Portuguese in the 17th century. It contains numerous churches and mosques, public buildings and merchants’ residences. Whydah, 23 m. west of Kotonu, is an old and formerly thickly-populated town. Its population is now about 15,000. It is built on the north bank of the coast lagoon about 2 m. from the sea. There is no harbour at the beach, and landing is effected in boats made expressly to pass through the surf, here particularly heavy. Whydah, during the period of the slave-trade, was divided into five quarters: the English, French, Portuguese, Brazilian and native. The three first quarters once had formidable forts, of which the French fort alone survives. In consequence of the thousands of orange and citron trees which adorn it, Whydah is called “the garden of Dahomé.” West of Whydah, on the coast and near the frontier of Togoland, is the trading town of Grand Popo. Inland in Dahomey proper are Abomey (q.v.), the ancient capital, Allada, Kana (formerly the country residence and burial-place of the kings of Dahomey) and Dogba. In the hinterland are Carnotville (a town of French creation), Nikki and Paraku, Borgu towns, and Garu, on the right bank of the Niger near the British frontier, the terminus of the railway from the coast.

Agriculture and Trade.—The agriculture, trade and commerce of Dahomey proper are essentially different from that of the hinterland (Haut Dahomey). The soil of Dahomey proper is naturally fertile and is capable of being highly cultivated. It consists of a rich clay of a deep red colour. Finely-powdered quartz and yellow micas are met with, denoting the deposit of disintegrated granite from the interior. The principal product is palm-oil, which is made in large quantities throughout the country. The district of Toffo is particularly noted for its oil-palm orchards. Palm-wine is also made, but the manufacture is discouraged as the process destroys the tree. Next to palm-oil the principal vegetable products are maize, guinea-corn, cassava, yams, sweet potatoes, plantains, coco-nuts, oranges, limes and the African apple, which grows almost wild. The country also produces ground-nuts, kola-nuts, pine-apples, guavas, spices of all kinds, ginger, okros (Hibiscus), sugar-cane, onions, tomatoes and papaws. Plantations of rubber trees and vines have been made. Cattle, sheep, goats and fowls are scarce. There is a large fishing industry in the lagoons. Round the villages, and here and there in the forest, clearings are met with, cultivated in places, but agriculture is in a backward condition. In the grassy uplands of the interior cattle and horses thrive, and cotton of a fairly good quality is grown by the inhabitants for their own use. The prosperity of the country depends chiefly on the export of palm-oil and palm-kernels. Copra, kola-nuts, rubber and dried fish are also exported, the fish going to Lagos. The adulteration of the palm-kernels by the natives, which became a serious menace to trade, was partially checked (1900–1903) by measures taken to ensure the inspection of the kernels before shipment. Trade is mainly with Germany and Great Britain, a large proportion of the cargo passing through the British port of Lagos. Only some 25% of the commerce is with France. Cotton goods (chiefly from Great Britain), machinery and metals, alcohol (from Germany) and tobacco are the chief imports. The volume of trade, which had increased from £701,000 in 1898 to £1,230,000 in 1902, declined in 1903 to £836,000 in consequence of the failure of rain, this causing a decrease in the production of palm-oil and kernels. In 1904 the total rose to £873,395. In 1905 the figure was £734,667, and in 1907 £853,051. By the Anglo-French Convention of 1898 the imposition of differential duties on goods of British origin was forbidden for a period of thirty years from that date.

Communications.—The Dahomey railway from Kotonu to the Niger is of metre gauge (3 ft. 6 in.). Work was begun in 1900, and in 1902 the main line was completed to Toffo, a distance of 55 m. Some difficulty was then encountered in crossing the Lagos Marsh, but by the end of 1905 the railway had been carried through Abomey to Pauignan, 120 m. from Kotonu. In 1907 the rails had reached Paraku, 150 m. farther north. A branch railway from the main line serves the western part of the colony. It goes via Whydah to Ségboroué on Lake Ahémé. Besides the railways, tramway lines exist in various parts of Dahomey. One, 28 m. long, runs from Porto Novo through the market-town of Adjara to Saka, close to the British frontier in the direction of Lagos. This line serves a belt of country rich in oil-palms. Kotonu is a regular port of call for steamers from Europe to the West Coast, and there is also regular steamship communication along the lagoons between Porto Novo and Lagos. There is a steamboat service between Porto Novo and Kotonu. A telegraph line connects Kotonu with Abomey, the Niger and Senegal.

Administration.—The colony is administered by a lieutenant-governor, assisted by a council composed of official and unofficial members. The colony is divided into territories annexed, territories protected, and “territories of political action,” but for administrative purposes the division is into “circles” or provinces. Over each circle is an administrator with extensive powers. Except in the annexed territories the native states are maintained under French supervision, and native laws and customs, as far as possible, retained. Natives, however, may place themselves under the jurisdiction of the French law. Such natives are known as “Assimilés.” In general the administrative system is the same as that for all the colonies of French West Africa (q.v.). The chief source of revenue is the customs, while the capitation tax contributes most to the local budget.

History.—The kingdom of Dahomey, like those of Benin and Ashanti, is an instance of a purely negro and pagan state, endowed with a highly organized government, and possessing a certain amount of indigenous civilization and culture. Its history begins about the commencement of the 17th century. At that period the country now known as Dahomey was included in the extensive kingdom of Allada or Ardré, of which the capital was the present town of Allada, on the road from Whydah
DAHOMEY

to Abomey. Allada became dismembered on the death of a reigning sovereign, and three separate kingdoms were constituted under his three sons. One state was formed by one brother round the old capital of Allada, and retained the name of Allada or Ardrah; another brother migrated to the east and formed a state known under the name of Porto Novo; while the third brother, Takudonu, travelled northwards, and after some vicissitudes established the kingdom of Dahomey. The word Dahomey means "in Danh's belly," and is explained by the following legend which, says Sir Richard Burton, "is known (1864) to everybody in the kingdom." Takudonu having settled in a town called Uhawwe encroached on the land of a neighbouring chief named Danh (the snake). Takudonu weared Danh by perpetual demands for land, and the chief one day exclaimed in anger "soon thou wilt build in my belly." So it came to pass. Takudonu slew Danh and over his grave built himself a palace which was called Dahomey, a name thenceforth adopted by the new king's followers. About 1724-1725 Dahomey, having become a powerful state, invaded and conquered successively Allada and Whydah. The Whydahs made several attempts to recover their freedom, but without success; while on the other hand the Danh of Allada was invaded, murdered, and replaced by a new king, which, in 1864, was constituted a separate domain. In 1863, the Danh of Allada, who was the last of the Danh dynasty, died. His son, Gezo, took the throne, and, with the support of his French allies, he seized control of the kingdom.

In 1851 Gezo attacked Abeokuta in the Yoruba country and the centre of the Egba power, but was beaten back. In the same year the king signed a commercial treaty with France, in which Gezo also undertook to preserve "the integrity of the territory belonging to the French fort" at Whydah. The fort secured by this treaty, was in the 17th century, and in 1842 made over to a French mercantile house. England, Portugal and Brazil also had "forts" at Whydah—all in a ruinous condition and ungarrisoned. But when in 1852 England, to prevent the slave-trade, blockaded the Dahomey coast, energetic protests were made by Portugal and France, based on the existence of these "forts." In 1858 Gezo died. He had greatly reduced the custom of human sacrifice, and left instructions that after his death there was to be no general sacrifice of the palace women.

Gezo was succeeded by his son Gléglé (or Ggléglé), whose attacks on neighbouring states, persecution of native Christians, and encouragement of the slave-trade involved him in difficulties with Great Britain and with France. It was, said Earl Russell, foreign secretary, to check "the aggressive spirit of the king of Dahomey" that England in 1861 annexed the island of Lagos. Nevertheless in the following year Gléglé captured Ishagga and in 1864 unsuccessfully attacked Abeokuta, both towns in the Lagos hinterland. In 1865 Commander Wilmot, R.N., and in 1866 Sir Richard Burton (the explorer and orientalist) were sent on missions to the king, but their efforts to induce the Dahomeyans to give up human sacrifices, slave-trading, &c, met with no success. In 1863, however, a step was taken by France which was the counterpart of the British annexation of Lagos. In that year the kingdom of Porto Novo accepted a French protectorate, and an Anglo-French agreement of 1864 fixed its boundaries. This protectorate was soon afterwards abandoned by Napoleon III., but was re-established in 1882. At this period the rivalry of European powers for possessions in Africa was becoming acute, and German agents appeared on the Dahomeyan coast. However, by an arrangement concluded in 1885, the German protectorate in Guinea was confined to Togo, save for the town of Lekki Popo at the western end of the lagoon of Grand Popo. In January 1886 Portugal—in virtue of her ancient rights at Whydah—announced that she had assumed a protectorate over the Dahomeyan coast, but she was induced by France to withdraw her protectorate in December 1887. Finally, the last international difficulty in the way of France was removed by the Anglo-French agreement of 1889, whereby Kotonou was surrendered by Great Britain. France claimed rights at Kotonou in virtue of treaties concluded with Gléglé in 1868 and 1878, but the chiefs of the town had placed themselves under the protection of the British at Lagos.

With the arrangements between the European powers the Dahomeyans had little to do, and in 1889, the year in which the Anglo-French agreement was signed, trouble arose between Gléglé and the French. The Dahomeyans were the more confident, as through German and other merchants at Whydah they were well supplied with modern arms and ammunition. Gléglé claimed the right to collect the customs at Kotonou, and to depose the king of Porto Novo, and proceeded to raid the territory of that potentate (his brother). A French mission sent to Abomey failed to come to an agreement with the Dahomeyans, who had already killed a French officer. A war followed, and the French declared a new king in France. Gléglé died on the 28th of December 1889, two days after the French mission had left his capital. He was succeeded by his son Behanzin. A French force was landed at Kotonou, and severe fighting followed in which the Amazons played a conspicuous part. In October 1890 a treaty was signed which secured to France Porto Novo and Kotonou, and to the king of Dahomey an annual pension of £800. It was unlikely that peace on such terms would prove lasting, and Behanzin's slave-raiding expeditions led in 1892 to a new war with France. General A. A. Dodds was placed in command of a strong force of Europeans and Senegalese, and after a sharp campaign during September and October completely defeated the Dahomeyan troops. Behanzin set fire to Abomey (entered by the French troops on the 17th of November) and fled north. Pursued by the enemy, abandoned by his people, he surrendered unconditionally on the 25th of January 1894, and was deported to Martinique, being transferred in 1906 to Algeria, where he died on the 10th of December of the same year.

In 1894, with the disintegration of Dahomey, the French divided the kingdom in two—Abomey and Allada—placing on the throne of Abomey a brother of the exiled monarch. Chief among the causes which led to the collapse of the Dahomeyan kingdom was the system which devoted the flower of its womanhood to the profession of arms.

Whydah and the adjacent territory was annexed to France by General Dodds on the 3rd of December 1892, and the rest of Dahomey placed under a French protectorate at the same time. The prince who had been made king of Abomey was found intriguing against the French, and in 1900 was exiled by them to the Congo, and with him disappeared the last vestige of Dahomeyan sovereignty.

Dahomey conquered, the French at once set to work to secure as much of the hinterland as possible. On the north they penetrated to the Niger, on the east they entered Borgu (a country claimed by the Royal Niger Company for Great Britain), on the west they overlapped the territory claimed by Germany as the "land of Togo." The struggle with Great Britain and Germany for supremacy in this region forms one of the most interesting chapters in the story of the partition of Africa. In the result France succeeded in securing a junction between Dahomey and her other possessions in West Africa, but failed to secure any part of the Niger navigable from the sea (see AFRICA: History, and NIGERIA). A Franco-German convention of 1867 settled the boundary on the west, and the Anglo-French convention of the 14th of June 1898 defined the frontier on the east. In 1899, on the disintegration of the French Sudan, the districts of Fada N'Gurma and Say, lying north of Borgu, were added to Dahomey, but in 1907 they were transferred to Upper Senegal-Niger, with which colony they are closely connected both geographically and ethnographically. From 1894 toward the French devoted great
attention to the development of the material resources of the country.

The "Customs."—Reference has already been made to the Dahomey "Customs," which gave the country an infamous notoriety. The "Customs" appear to date from the middle of the 17th century, and were of two kinds: the grand Customs performed on the death of a king; and the minor Customs, held twice a year. The horrors of these saturnalia of bloodshed were attributable not to a love of cruelty but to filial piety. Upon the death of a king human victims were sacrificed at his grave to supply him with wives, attendants, &c. in the spirit world. The grand Customs surpassed the annual rites in splendour and bloodshed. At those held in 1791 during January, February and March, it is stated that no fewer than 500 men, women and children were put to death. The minor Customs were first heard of in Europe in the early years of the 18th century. They formed continuations of the grand Customs, and "periodically supplied the departed monarch with fresh attendants in the shadowy world." The actual slaughter was preceded by dancing, feasting, speemachting and elaborate ceremonial. The victims, chiefly prisoners of war, were dressed in calico shirts decorated round the neck and down the sleeves with red bindings, and with a crimson patch on the left breast, and wore long white night-caps with spirals of blue ribbon sewn on. Some of them, tied in baskets, were at one stage of the proceedings taken to the top of a high platform, together with an alligator, a cat and a hawk in similar baskets, and paraded on the heads of the Amazons. The king then made a speech explaining that the victims were sent to testify to his greatness in spirit-land, the men and the animals each to their kind. They were then hurled down into the middle of a混ing crowd of natives, and butchered. At another stage of the festival human sacrifices were offered at the shrine of the king's ancestors, and the blood was sprinkled on their graves. This was known as Zan Nyamé or "evil night," the king going in procession with his wives and officials and himself executing the doomed. These semi-public massacres formed only a part of the slaughter, for many women, eunuchs and others within the palace were done to death privately. The skulls were used to adorn the palace walls, and the king's sleeping-chamber was paved with the heads of his enemies. The skulls of the conquered kings were turned into royal drinking cups, their conversion to this use being esteemed an honour. Sir Richard Burton insists (A Mission to Gele, King of Dahome) that the horrors of these rituals were greatly exaggerated. For instance, in his story, that the king floated a basket in a tank of human blood was, he writes, quite untrue. He denies, too, that the victims were tortured, and affirms that on the contrary they were treated humanely, and, in many cases, even acquiesced in their fate. It seems that cannibalism was a sequel of the Customs, the bodies of the slaughtered being roasted and devoured smoking hot. On the death of the king the wives, after the most extravagant demonstrations of grief, broke and destroyed everything within their reach, and attacked and murdered each other, the uproar continuing until order was restored by the new sovereign.

Amazonian Army.—The training of women as soldiers was the most singular Dahomeyan institution. About one-fourth of the whole female population were said to be "married to the fetich," many even before their birth, and the remainder were merely at the disposal of the king. The most favoured were selected as his own wives or enlisted into the regiments of Amazons, and the chief men were liberally supplied. Of the female captives the most promising were drafted into the ranks as soldiers, and the rest became Amazonian camp followers and slaves in the royal households. These female levies formed the flower of the Dahomeyan army. They were marshalled in regiments, each with its distinctive uniform and badges, and they took the post of honour in all battles. Their number has been variously stated. Sir R. F. Burton, in 1862, who saw the army marching out of Kano on an expedition, computed the whole force of female troops at 2,500, of whom one-third were unarmed or only half-armed. Their weapons were blunderbusses, flint muskets, and bows and arrows. A later writer estimated the number of Amazons at 1,000, and the male soldiers at 10,000. The system of warfare was one of surprise. The army marched out, and, when within a few days' journey of the town to be attacked, silence was enjoined and no fires permitted. The regular highways were avoided, and the advance was by a road specially cut through the bush. The town was surrounded at night, and just before daybreak a rush was made and every soul captured if possible; none were killed except in self-defence, as the first object was to capture, not to kill. The season usually selected for expeditions was from January to March, or immediately after the annual "Customs." The Amazons were carefully trained, and the king was in the habit of holding "autumn manoeuvres" for the benefit of foreigners. Many Europeans have witnessed a mimic assault, and agree in ascribing a marvelous power of endurance to the women. Lines of the Amazons were piled up one behind the other to represent defences, and at a given signal the Amazons, barefooted and without any special protection, charged and disappeared from sight. Presently they emerged within the lines torn and bleeding, but apparently insensible to pain, and the parade closed with a march past, each warrior leading a pretended captive bound with a rope.

DAILÉ (DALLAIS), JEAN (1594-1670), French Protestant divine, was born at Châtellerault and educated at Poitiers and Lyons. From 1612 to 1621 he was tutor to two of the grandsons of Philippe de Morais, seigneur de Flers and Marly. Ordained to the ministry in 1617, he went over to the French huguenots, and, to Du Plessis Mornay, whose memoirs he subsequently wrote. In 1625 Dailé was appointed minister of the church of Saumur, and in 1626 was chosen by the Paris consistory to be minister of the church of Charenton. Of his works, which are principally controversial, the best known is the treatise Du vrai emploi des Pers (1631), translated into English by Thomas Smith under the title A Treatise concerning the right use of the Fathers (1651). The work attacks those who made the authority of the Fathers conclusive on matters of faith and practice. Dailé contends that the text of the Fathers is often corrupt, and that even when it is correct their reasoning is often illogical. In his Sermons on the Philippinans and Colossians, Dailé vindicated his claim to rank as a great preacher as well as an able controversialist. He was president of the Consistory held at Loire, which met at Loir in 1659 (H. M. Baird, The Huguenots and the Revocation of the Edict of Nantes, 1895, pp. 412 ff.), when, as in the Apologie des Synodes d'Alençon and de Charenton (1655), he defended the universalism of Moses Amyraut. He wrote also Apologie pour les Eglises Réformées et La Foî fondée sur les Saintes Écritures. His life was written by his son Adrien, who retired to Zürich at the revocation of the edict of Nantes.

DAIRY and DAIRY-FARMING (from the Mid. Eng. deieris, from dey, a maid-servant, particularly one about a farm; cf. Norw. deia, as in be-deia, a maid in charge of live-stock, and in other compounds; thus "dairy" means that part of the farm buildings where the "dey" works). Milk, either in its natural state, or in the form of butter and cheese, is an article of diet so useful, wholesome and palatable, that dairy management, which...
DAIRY

includes all that concerns its production and treatment, constitutes a most important branch of husbandry. The physical conditions of the different countries of the world have determined in each case the most suitable animal for dairy purposes. The Laplander obtains his supplies of milk from his rein-deer, the roving Tatar from his mares, and the Bedouin of the desert from his camels. In the temperate regions of the earth many pastoral tribes subsist mainly upon the milk of the sheep. In some rocky regions the goat is invaluable as a milk-yielder; and the buffalo is equally so amid the swamps and jungles of tropical climates. The milking of ewes was once a common practice in Great Britain; but it has fallen into disuse because of its hurtful effects upon the flock. A few milch asses and goats are here and there kept for the benefit of infants or invalids; but with these exceptions the cow is the only animal now used for dairy purposes.

No branch of agriculture underwent greater changes during the closing quarter of the 19th century than dairy-farming; within the period named, indeed, the dairying industry may be said to have been revolutionized. The two great factors in this modification were the introduction about the year 1850 of the chemical cream-separator and, when the old slow way of raising cream in pans was dispensed with, and the invention some ten years later of a quick and easy method of ascertaining the fat content of samples of milk without having to resort to the tedious processes of chemical analysis. About the year 1875 the agriculturists of the United Kingdom, influenced by various economic causes, began to turn their thoughts more intently in the direction of dairy-farming, and to the increased production of milk and cream, butter and cheese. On the 24th of October 1876 was held the first London dairy show, under the auspices of a committee of agriculturists, and it has been followed by a similar show in every subsequent year. The official report of the pioneer show stated that "there was a much larger attendance and a greater amount of enthusiasm in the movement than even the most sanguine of its promoters anticipated." On the day named Professor J. Prince Sheldon read at the show a paper on the dairying industry, and proposed the formation of a society to be called the British Dairy Farmers' Association. This was unanimously agreed to, and thus was founded an organization which has since been closely identified with the development of the dairying industry of the United Kingdom. In its earlier publications the Association was wont to reproduce from Household Words the following tribute to the cow:

"If civilized people were ever to lapse into the worship of animals, the Cow would certainly be their chief goddess. What a fountain of blessings is the Cow! She is the mother of beef, the source of butter, the original cause of cheese, to say nothing of her hair-combs and upper leather. A gentle, amiable, ever-yielding creature, who has no joy in her family affairs which she does not share with man. We rob her of her children that we may rob her of her milk, and we only care for her when the robbing may be perpetrated.

The association has, directly or indirectly, brought about many valuable reforms and improvements in dairying. Its London dairy has provided, year after year, a varied, object-lessons in cheese, butter and dairy equipment. In order to demonstrate to producers what is the ideal to aim at, there is nothing more effective than a competitive exhibition of products, and the approach to uniform excellence of character in cheese and butter of whatever kinds is most obvious to those who remember what these products were like at the first two or three dairy shows. Simultaneously there has been a less marked advance in the mechanical aids to dairying, including, in particular, the centrifugal cream-separator, the crude germ of which was first brought before the public at the international dairy show held at Hamburg in the spring of 1877. The association in good time set the example, now beneficially followed in many parts of Great Britain, of providing means for technical instruction in the making of cheese and butter, by the establishment of a dairy school in the Vale of Aylesbury, subsequently removing it to new and excellent premises at Reading, where it is known as the British Dairy Institute. The initiation of butter-making contests at the annual dairy shows stimulated the competitive instinct of dairy workers, and afforded the public useful object-lessons, in more real than yearly milking competitions have been added. Milking trials and butter tests of cows conducted at the dairy shows have afforded results of much practical value. Many of the larger agricultural societies have found it expedient to include in their annual shows a working dairy, wherein butter-making contests are held and public demonstrations are given.

What are regarded as the dairy breeds of cattle is illustrated by the prize schedule of the annual London dairy show, in which sections are provided for cows and heifers of the Shorthorn, Jersey, Guernsey, Red Poll, Ayrshire, Kerry and Dexter breeds (see CATTLE). A miscellaneous class is also provided, the entries in which are mostly cross-breds. There are likewise classes for Shorthorn bulls, Jersey bulls, and bulls of any other pure breed, but it is stipulated that all bulls must be of proved descent from dams that have won prizes in the milking trials or butter tests of the British Dairy Farmers' Association or other high-class agricultural society. The importance of securing dairy characters in the sire is thus recognized, and it is noticed that, as the object of the bull classes is to encourage the breeding of pure breeds for dairy purposes, the entries are given solely to animals exhibited in good stock getting condition.

Milk and Butter Tests

The award of prizes in connexion with milking trials cannot be determined simply by the quantity of milk yielded in a given period, say twenty-four hours. Other matters must obviously be taken into consideration, such as the quality of the milk and the time that has elapsed since the birth of the last calf. With regard to the former point, for example, it is quite possible for one cow to give more milk than another, but for the milk of the second cow to include the larger quantity of butter-fat. The awards are therefore determined by the total number of points obtained according to the following scheme:

One point for every ten days since calving (deducing the first forty days), with a maximum of fourteen points.

One point for every pound of milk, taking the average of two days' yield.

Twenty points for every pound of butter-fat produced.

Four points for every pound of "solids other than fat."

Deduct 5% for each point below average."

This method of award is at present the best that can be devised, but it is possible that, as experience accumulates, some rearrangement of the points may be found to be desirable. Omitting many of the details, Table I. shows some of the results in the case of Shorthorn and Jersey prize cows. The days "in milk" denote in each case the number of days that have elapsed since calving; and if the one day's yield of milk is desired in gallons, it can be obtained approximately by dividing the weight in tons by 10-3 lb, so that very little error is involved in converting pounds to gallons by dividing the number of pounds by 10.
pounds by 10: thus, the Shorthorn cow Heroine III. gave 52.4 lb, or 5.24 gallons, of milk per day. The table is incidentally of interest as showing how superior as milch kine are the unregistered or non-pedigree Shorthorns—which are typical of the great majority of dairy cows in the United Kingdom—as compared with the pedigree animals entered, or eligible for entry, in Coates’s Herd-Book. The evening’s milk, it should be added, is nearly always richer in fat than the morning’s, but the percentages in the table relate to the entire day’s milk.

The milking trials are based upon a chemical test, as it is necessary to determine the percentage of fat and of solids other than fat in each sample of milk. The butter test, on the other hand, is a churn test, as the cream has to be separated from the milk and churned. The following is the scale of points used at the London dairy show in making awards in butter tests:

One point for every ounce of butter; one point for every completed ten days since calving, deducting the first forty days. Maximum allowance for period of lactation, 12 points.

Fractions of ounces of butter, and incomplete periods of less than ten days, to be worked out in decimals and added to the total points.

In the case of cows obtaining the same number of points, the prize to be awarded to the cow that has been the longest time in milk.

No prize or certificate to be given in the case of:

(a) Cows under five years old failing to obtain 28 points.
(b) Cows five years old and over failing to obtain 32 points.

The manner in which butter tests are decided will be rendered clear by a study of Table II. It is seen that whilst the much larger Shorthorn cows—having a bigger frame to maintain and consuming more food—gave both more milk and more butter in the day of twenty-four hours, the Jersey milk was much the richer in fat. In the case of the first-prize Jersey the "butter ratio," as it is termed, was excellent, as only 13.83 lb of milk were required to yield 1 lb of butter; in the case of the second-prize Shorthorn, practically twice this quantity (27.11 lb) was needed. Moreover, if the days in milk are taken into account, the difference in favour of the Jersey is seen to be 123 days.

The butter-yielding capacity of the choicest class of butter cows, the Jerseys, is amply illustrated in the results of the butter tests conducted by the English Jersey Cattle Society over the period of fourteen years 1886 to 1890 inclusive. These tests were carried out year after year at half a dozen different shows, and the results are classified in Table III, according to the age of the animals. The average time in milk is measured by the number of days since calving, and the milk and butter yields are those for the day of twenty-four hours. The last column shows the "butter ratio." This number is lower in the case of the Jerseys than in that of the general run of dairy cows. The average results from the total of 1023 cows of the various ages are:—One day’s milk, 32 lb 24 oz., equal to about 3 gallons or 12 quarts; one day’s butter, 1 lb 10 1/2 oz.; butter ratio, 19.13 or about 16 pints of milk to 1 lb of butter. Individual yields are sometimes extraordinarily high. Thus at the Tring show in 1899 the three leading Jersey cows gave the following results:

<table>

The eight prize-winning Jerseys on this occasion, with an average weight of 916 lb and an average of 117 days in milk, yielded an average of 2 lb 9 oz. of butter per cow in the twenty-four hours, the butter ratio working out at 16.69. At the Tring show of 1900 a Shorthorn cow Cherry gave as much as 4 lb 14 oz. of butter in twenty-four hours; she had been in milk 41 days, and her butter ratio worked out at 15.79, which is unusually good for a big cow.

In the six years 1895 to 1900 inclusive 285 cows of the Shorthorn, Jersey, Guernsey and Red Polled breeds were subjected to butter tests at the London dairy show, and the general results are summarized in Table IV.

Although cows in the showyard may perhaps be somewhat upset by their unusual surroundings, and thus not yield so well as at home, yet the average results of these butter-test trials over a number of years are borne out by the private trials that have taken place in various herds. The trials have, moreover, brought into prominence the peculiarities of different breeds, such as: (a) that the Shorthorns, Red Polls and Kerries, being cattle whose milk contains small fat globules, are better for milk than the Jerseys and Guernseys, whose milk is richer, containing larger-sized fat globules, and is therefore more profitable for converting into butter; (b) that the weights of the animals, and consequently the proportionate food, must be taken into account in estimating the cost of the dairy produce; (c) that the influence of the stage reached in the period of lactation is much more marked in some breeds than in others.

An instructive example of the milk-yielding capacity of Jersey cows is afforded in the carefully kept records of Lord Rothschild’s herd at Tring Park, Herts. Overleaf are given the figures for four years, the gallons being calculated at the rate of 10 lb of milk to the gallon.

</table>
In 1897, 30 cows averaged 6396 lb, or 640 gallons per cow.

In 1898, 29 " " 6209 " 621 "

In 1899, 37 " " 6430 " 643 "

In 1900, 39 " " 6136 " 614 "

The average over the four years works out at about 630 gallons per cow per annum.

Cows of larger type will give more milk than the Jerseys, but it is less rich in fat. The milk record for the year 1900 of the herd of Red Polled cattle belonging to Mr Garrett Taylor, Whittleingham, Norfolk, affords a good example. The cows in the herd, which had before 1900 produced one or more calves, and in 1900 added another to the list, being in full profit the greater part of the year, numbered 82. Their total yield was 521,950 lb of milk, or an average of 6365 lb—equivalent to about 636 gallons per cow. In 1899 the average yield of 50 cows was 53 lb 628 gallons; in 1898 the average yield of 76 cows was 6473 lb or 647 gallons. Of cows which dropped a first calf in the autumn of 1899, one of them—Lemon—milked continuously for 462 days, yielding a total of 7166 lb of milk, being still in milk when the herd year closed on the 27th of December. Similar cases were those of Nora, which gave 9066 lb of milk in 455 days; Doris, 8138 lb in 462 days; Brisk, 9248 lb in 469 days; Della, 8806 lb in 434 days, drying 28 days before the year ended; and Lottie, 637 lb in 394 days, also drying 28 days before the year ended; these were all cows with their first calf. Eight cows in the herd gave milk on every day of the 52 weeks, and 30 others had their milk recorded on 300 days or more. Three heifers which produced a first calf before the 11th of April 1900, averaged in the year 4569 lb of milk, or about 456 gallons. In 1900 three cows, Ewyke Jessie, Kathleen and Dos, each gave over 10,000 lb, or 1000 gallons of milk; four cows gave from 9000 lb to 10,000 lb, two from 8000 lb to 9000 lb, 17 from 7000 lb to 8000 lb, 19 from 6000 lb to 7000 lb, 30 from 5000 lb to 6000 lb, and 16 from 4000 lb to 5000 lb.

The practice of taking the milk register, as followed in a well-known dairy, may be briefly described. The cows are always milked in the stalls, and during summer they are brought in twice a day for this purpose. After each cow is milked, the pail containing the whole of her milk is hung on a spring balance suspended in a convenient position, and from the gross weight indicated there is deducted the already known weight of the pail. The difference, which represents the weight of milk, is recorded in a book suitably ruled. This book, when open, presents a view of one week's records. In the left-hand column are the names of the cows; on the right of this are fourteen columns, two of which receive the morning and evening record of each cow. In a final column on the right appears the week's total yield for each cow; and space is also allowed for any remarks.

1 Portable milk-weighing appliance is made in which the weight of the pail is included, and an indicator shows on a dial the exact weight in pounds and ounces, and likewise the volume in gallons and pints, of the milk in the pail. When the pail is empty the indicator of course points to zero.

Fractions of a pound are not entered, but 18 lb 12 oz. would be recorded as 19 lb, whereas 21 lb 5 oz. would appear as 21 lb, so that a fraction of one pound is considered as a whole pound, and a fraction of under half a pound is ignored. By dividing the pounds by 10 the yield in gallons is readily ascertained.

Every dairy farmer has some idea, as to each of his cows, whether she is a good, a bad or an indifferent milker, but such knowledge is at best only vague. By the simple means indicated the character of each cow as a milk-producer is slowly but surely recorded in a manner which is at once exact and definite. Such a record is particularly valuable to the farmer, in that it shows him the relative milk-yielding capacities of his cows, and thus enables him gradually to weed out the naturally poor milkers and replace them by better ones. It also guides him in regulating the supply of food according to the yield of milk. The register will, in fact, indicate unerringly which are the best milk-yielding cows in the dairy, and which therefore are, with the milking capacity in view, the best to breed from.

The simplicity and inexpensiveness of the milk register must not be overlooked. These are features which should commend especially to the notice of small dairy farmers, for with a moderate number of cows it is fairly easy to introduce the register. But even with a large dairy it will be found that, as soon as the system has got fairly established, the additional time and trouble involved will sink into insignificance when compared with the benefits which accrue.

The importance of ascertaining not only the quantity but also, the quality of milk is aptly illustrated in the case of two cows at the Tring show, 1900. The one cow gave in 24 hours 44 gallons of milk, which at 7d. per gallon would work out at about 28s. 7d.; she made 2 lb 12 oz. of butter, which at 15s. 4d. per lb would bring in 3s. 8d.; consequently by selling the milk the owner lost about 1s. 1d. per day. The second cow gave 55 gallons of milk, which would work out at 3s. 1d.; she made 1 lb 12 oz. of butter, which would only be worth 2s. 4d., so that by converting the milk into butter the owner lost 9d. per day.

The colour of milk is to some extent an indication of its quality—the deeper the colour the better the quality. The colour depends upon the size of the fat globules, a deep yellowish colour indicating large globules of fat. When the globules are of large size the milk churns more readily, and the butter is better both in quality and in colour.

The following fifty dairy rules relating to the milking and general management of cows, and to the care of milk and dairy utensils, were drawn up on behalf of, and published by, the United States department of agriculture at Washington. They are given here with a few merely verbal alterations:

The Owner and his Helpers

1. Read current dairy literature and keep posted on new ideas.
2. Observe and enforce the utmost cleanliness about the cattle, their attendants, the cow-house, the dairy and all utensils.
3. A person suffering from any disease, or who has been exposed to a contagious disease, must remain away from the cows and the milk.

The Cow-House

4. Keep dairy cattle in a shed or building by themselves. It is preferable to have no cellar below and no storage loft above.
5. Cow-houses should be well ventilated, lighted and drained; should have tight floors and walls, and be plainly constructed.
6. Never use rusty or dirty litter.
7. Allow no straw or manure material in the cow-house for any length of time. Store the manure under cover outside the cow-house, and remove it to a distance as often as practicable.
8. Whitewash the cow-house once or twice a year; use gypsum in the manure gutters daily.
9. Use no dry, dusty feed prior to milking; if fodder is dusty, sprinkle it before it is fed.
10. Clean and thoroughly air the cow-house before milking; in hot weather sprinkle the floor.
11. Keep the cow-house and dairy room in good condition, and then insist that the dairy, factory or place where the milk goes be kept equally well.
DAIRY

12. Have the herds examined at least twice a year by a skilled veterinarian.
13. Promptly remove from the herd any animal suspected of being in bad health, and reject her milk. Never add an animal to the herd until it is ascertained to be free from disease, especially tuberculosis.
14. Do not move cows faster than a comfortable walk while on the way to the place of milking or feeding.
15. Never allow the cows to be excited by hard driving, abuse, loud talking or unnecessary disturbance; do not expose them to cold or storms.
16. Do not change the feed suddenly.
17. Feed liberally, and use only fresh, palatable feed-stuffs; in no case should decomposed or mouldy material be used.
18. Provide water in abundance, easy of access, and always pure; fresh, but not too cold.
19. Salt should always be accessible to the cows.
20. Do not allow any strong-flavoured food, like garlic, cabbages and turnips, to be eaten, except immediately after milking.
21. Clean the entire skin of the cow daily. If hair in the region of the udder is not easily kept clean, it should be clipped.
22. Do not use the milk within twenty days before calving, nor for three to five days afterwards.

MILKING

23. The milkers should be clean in all respects; he should not use tobacco while milking; he should wash and dry his hands just before milking.
24. The milkers should wear a clean outer garment, used only when milking and kept in a clean place at other times.
25. Brush the udder and surrounding parts just before milking and wipe them with a clean damp cloth or sponge.
26. Milk quietly, quickly, cleanly and thoroughly. Cows do not like unnecessary noise or delay. Commence milking at exactly the same hour every morning and evening, and milk the cows in the same order.
27. Throw away (but not on the floor—better in the gutter) the first two or three streams from each teat; this milk is very watery and of little value, but it may injure the rest.
28. If in any milking a part of the milk is bloody or stringy or appears in appearance, the whole should be rejected.
29. Milk with dry hands; never let the hands come in contact with the milk.
30. Do not allow dogs, cats or loafers to be around at milking time.
31. If any accident occurs by which a pail, full or partly full, of milk becomes dirty, do not try to remedy this by straining, but reject all this milk and rinse the pail.
32. Weigh and record the milk given by each cow, and take a sample morning and night, at least once a week, for testing by the fat test.

CARE OF MILK

33. Remove the milk of every cow at once from the cow-house to a clean dry room, where the air is pure and sweet. Do not allow cans to remain in the cow-house while they are being filled with milk.
34. Strain the milk through a metal gauze and a flannel cloth or layer of cotton as soon as it is drawn.
35. Cool the milk as soon as strained—to 45°F. If the milk is for shipment, or to 60° if for home use or delivery to a factory.
36. Never close a can containing warm milk. If the cover is left off the can, a piece of cloth or mosquito netting should be used to keep out insects.
37. If milk is stored, it should be kept in tanks of fresh cold water (renewed as often as the temperature increases to any material extent) in a clean, dry room. Unless it is desired to remove cream, it should be stirred with a tin stirrer often enough to prevent the forming of a thick cream layer.
38. Keep the night milk under shelter so that rain cannot get into the cans. In warm weather keep it in a tank of fresh cold water.
39. Never mix fresh warm milk with that which has been cooled.
40. Do not allow the milk to freeze.
41. In no circumstances should anything be added to milk to prevent its souring. Cleanliness and cold are the only preventives needed.
42. All milk should be in good condition when delivered at a creamery or the same. This may make it necessary to deliver twice a day during the hottest weather.
43. When cans are hauled far they should be full, and carried in a spring wagggon.
44. In hot weather cover the cans, when moved in a wagggon, with a clean wet blanket or canvas.

THE UDDERTAIL

46. Milk utensils for farm use should be made of metal and have all joints smoothly soldered. Never allow them to become rusty or rough inside.

47. Do not haul waste products back to the farm in the cans used for delivering milk. When this is unavoidable, insist that the skim milk or whey tank be kept clean.
48. Cans used for the return of skim milk or whey should be emptied, scalded and cleaned as soon as they arrive at the farm.
49. Clean all dairy utensils by first thoroughly rinsing them in warm water; next clean inside and out with a brush and hot water in which a cleaning material is dissolved; then rinse and, lastly, sterilize by boiling water or steam. Use pure water only.
50. After cleaning, keep utensils inverted in pure air, and sun if possible, until wanted for use.

FOOD AND MILK PRODUCTION

In their comprehensive paper relating to the feeding of animals published in 1895, Lawes and Gilbert discussed amongst other questions that of milk production, and directed attention to the great difference in the demands made on the food—the one hand for the production of meat (that is, of animal increase), and on the other for the production of milk. Not only, however, do cows of different breeds yield different quantities of milk, and milk of characteristically different composition, but individual animals of the same breed have very different milk-yielding capacity; and whatever the capacity of a cow may be, she has a maximum yield at one period of her lactation, which is followed by a gradual decline. Hence, in comparing the amounts of constituents stored up in the fattening increase of an ox with the amounts of the same constituents removed in the milk of a cow, it is necessary to assume a wide range of difference in the yield of milk. Accordingly, Table V. shows the Table V.—Comparison of the Constituents of Food carried off in Milk, and in the Fattening Increase of Oxen.

In Increase in Live-Weight per Week.—Oxen.

| If 10 lb increase | 0-75 | 6-35 | 0-15 | 7-25 |
| If 15 lb increase | 1-13 | 9-53 | 0-22 | 10-88 |

amounts of nitrogenous substance, of fat, of non-nitrogenous substance not fat, of mineral matter, and of total solid matter, carried off in the weekly yield of milk of a cow, on the alternative assumptions of a production of 4, 6, 8, 10, 12 hours, or 14, 16, 18 or 20 quarts per head per day. For comparison, there are given at the foot of the table the amounts of nitrogenous substance, of fat, of mineral matter, and of total solid matter, in the weekly increase in live-weight of a fattening ox of an average weight of 1000 lb—on the assumption of a weekly increase, first, of 10 lb, and, secondly, of 15 lb. The estimates of the amounts of constituents in the milk are based on the assumption that it will contain 12-5% of total solids—consisting of 3-65 albuminoids, 3-50 butter-fat, 4-60 sugar and 0-75 of mineral matter. The estimates of the constituents in the fattening increase of oxen are founded on determinations made at Rothamsted.

With regard to the very wide range of yield of milk per head per day which the figures in the following table assume, it may be remarked that it is by no means impossible that the same animal might yield the largest amount, namely, 20 quarts, or 5 gallons, per day near the beginning, and only 4 quarts, or
1 gallon, or even less, towards the end of her period of lactation.

At the same time, an entire herd of, for example, Shorthorns or Ayrshires, of fairly average quality, well fed, and including animals at various periods of lactation, should not yield an average of less than 8 quarts, or 2 gallons, and would seldom exceed 10 quarts, or 2½ gallons, per head per day the year round.

For the sake of illustration, an average yield of milk of 10 quarts, equal 24 lb, or between 25 and 26 lb per head per day, may be assumed, and the amount of constituents in the weekly yield at this rate may be calculated with that in the weekly increase of the fattening ox at the higher rate assumed in the table, namely, 15 lb per 1000 lb live-weight, or 1.5% per week. It is seen that whilst of the nitrogenous substance of the food the amount stored up in the fattening increase of an ox would be only 1.13 lb, the amount carried off as such in the milk would be 6.6 lb, or nearly six times as much. Of mineral matter, again, whilst the fattening increase would only require about 0.22 lb, the milk would carry off 1.35 lb, or again about six times as much. Of fat, however, whilst the fattening increase would contain 9.53 lb, the milk would contain only 6.33 lb, or only about two-thirds as much. On the other hand, whilst the fattening increase contains no other non-nitrogenous substance than fat, the milk would carry off 8.42 lb in the form of milk-sugar. This amount of milk-sugar reckoned as fat, would correspond approximately to the difference between the fat in the milk and that in the fattening increase.

It is evident, then, that the drain upon the food is very much greater for the production of milk than for that of meat. This is especially the case in the important item of nitrogenous substance; and if, as is frequently assumed, the butter-fat of the milk is at any rate largely derived from the nitrogenous substance of the food, so far as it is so at least about two parts of such substance would be required to produce one of fat. On such an assumption, therefore, the drain upon the nitrogenous substance of the food would be very much greater than that indicated in the table as existing as nitrogenous substance in the milk.

To this point further reference will be made presently.

Attention may next be directed to the amounts of food, and of certain of its constituents, consumed for the production of a given amount of milk. This point is illustrated in Table VI., which shows the constituents consumed per 1000 lb live-weight per day in the case of the Rothamsted herd of 30 cows in the spring of 1884. On the left hand are shown the actual amounts of the different foods consumed per 1000 lb live-weight per day; and in the respective columns are recorded — first the amounts of total dry substance which the foods contained, and then the amounts of digestible nitrogenous, digestible non-nitrogenous (reckoned as starch), and digestible total organic substance which the different foods would supply; these being calculated according to Lawes' and Gilbert's own estimates of the percentage composition of the foods, and to Wolff's estimates of the proportion of the several constituents which would be digestible.

The first column shows that the amount of total dry substance of food actually consumed by the herd, per 1000 lb live-weight per day, was scarcely 20 lb, whilst Wolff's estimated requirement, as stated at the foot of the table, is 24 lb. But his ration would doubtless consist to a greater extent of hay and straw-chaff, containing a larger proportion of indigestible and effete woody fibre. The figures show, indeed, that the Rothamsted ration supplied, though nearly the same, even a somewhat less amount of total digestible constituents than Wolff's.

Of digestible nitrogen substance the food supplied 2.64 lb per 1000 lb live-weight per day; the amount required for sustenance is merely 0.57 lb; leaving, therefore, 2.07 lb available for milk production. The 2.3 lb of milk yielded per 1000 lb live-weight per day would, however, contain only 0.85 lb; and there would thus remain an apparent excess of 1.22 lb of digestible nitrogenous substance in the food supplied. But against the amount of 2.64 lb actually consumed, Wolff's estimate of the amount required for sustenance and for milk-production is 2.5 lb, or but little less than the amount actually consumed at Rothamsted. On the assumption that the expenditure of nitrogenous substance in the production of milk is only in the formation of the nitrogenous substances of the milk, there would appear to have been a considerable excess given in the food.

It has been shown that although it is possible that some of the fat of a fattening animal may be produced from the albuminoids; yet, within certain limits, its food, rich in carbohydrates, it points to the conclusion that both the yield of milk and its richness in butter are more connected with a liberal supply of the nitrogenous constituents in the food. Obviously, so far as this is the case, it may be only that thereby more active change is Ibn the system, and therefore greater activity of the special function, is maintained. The evidence at command is, at any rate, not inconsistent with the supposition that a good deal of the fat of milk may have its source in the breaking up of albuminoids, but direct evidence on the point is still wanting; and supposing such breaking up to take place in the gland, the question arises — What becomes of the by-products? Assuming, however, that such change does take place, the amount of nitrogenous substance supplied to the Rothamsted cows would be less

*Albuminoid ratio, 1-44.
† Excessive of 0-4 fat; albuminoid ratio, 1-5.4.

1 Landw. Futterungslehre, 5te Aufl., 1888, p. 249.
in excess of the direct requirement for milk-production than the figures in the table would indicate, if, indeed, in excess at all.

The figures in the column of Table VI, relating to the estimated amount of digestible non-nitrogenous substance reckoned as starch show that the quantity actually consumed was 11.71 lb, whilst the amount estimated by Wolff to be required was 12.5 lb, besides 0.4 lb of fat. The figures further show that, deducting 7.4 lb for sustenance from the quantity actually consumed, there would remain 4.31 lb available for milk-production, whilst only about 3.02 lb would be required supposing that both the fat of the milk and the sugar had been derived from the carbohydrates of the food; and, according to this calculation, there would still be an excess in the daily food of 1.29 lb. It is to be borne in mind, however, that estimates of the requirement for mere sustenance are mainly founded on the results of experiments in which the animals are allowed only such a limited amount of food as will maintain them without either loss or gain when at rest. But physiological considerations point to the conclusion that the expenditure, independently of loss or gain, will be the greater the more liberal the ration, and hence it is probable that the real excess, if any, over that required for sustenance and milk-production would be less than that indicated in the table, which is calculated on the assumption of a fixed requirement for sustenance for a given live-weight of the animal. Supposing that there really was any material excess of either the nitrogenous or the non-nitrogenous constituents supplied over the requirement for sustenance and milk-production, the question arises—Whether, or to what extent, it conduced to increase in live-weight of the animals, or whether it was in part, or wholly, voided, and so wasted.

As regards the influence of the period of the year, with its characteristic changes of food, on the quantity and composition of the milk, the first column of the second division of Table VII. shows the average yield of milk per head per day of the Rothamsted herd, averaging about 42 cows, almost exclusively Short-horns, in each month of the year, over six years, 1884 to 1889.

*Average over five years only, as the records did not commence until February 1884.

It should be stated that the Rothamsted cows had cake throughout the year; at first 4 lb per head per day, but afterwards graduated according to the yield of milk, on the basis of 4 lb for a yield of 28 lb of milk, the result being that then the amount given averaged more per head per day during the grazing period, but less earlier and later in the year. Bran, hay and straw-chaff, and roots (generally mangel), were also given when the animals were not turned out to grass. The general plan was, therefore, to give cake alone in addition when the cows were turned out to grass, but some other dry food, and roots, when entirely in the shed during the winter and early spring months.

Referring to the column showing the average yield of milk per head per day each month over the six years, it will be seen that during the six months January, February, September, October, November and December the average yield was sometimes below 20 lb, and on the average only about 21 lb of milk per head per day; whilst over the other six months it averaged 27.63 lb, and over May and June more than 32 lb, per head per day. That is to say, the quantity of milk yielded was considerably greater during the grazing period than when the animals had more dry food, and roots instead of grass.

Next, referring to the particulars of composition, according to Dr Vieth's results, which may well be considered as typical for the different periods of the year, it is seen that the specific gravity of the milk was only average, or lower than average, during the grazing period, but rather higher in the earlier and later months of the year. The percentage of total solids was rather lower than the average at the beginning of the year, lowest during the chief grazing months, but considerably higher in the later months of the year, when the animals were kept in the shed and received more dry food. The percentage of butter-fat follows very closely that of the total solids, being the lowest during the best grazing months, but considerably higher than the average during the last four or five months of the year, when more dry food was given. The percentage of solids not fat was considerably the lowest during the later months of the grazing period, but average, or higher than average, during the earlier and later months of the year. It may be observed that, according to the average percentages given in the table, a gallon of milk will contain more of both total solids and of butter-fat in the later months of the year; that is, when there is less grass and more dry food given.

Turning to the last three columns of the table, it is seen that although, as has been shown, the percentage of the several constituents in the milk is lower during the grazing months, the actual amounts contained in the quantity of milk yielded per head are distinctly greater during those months. Thus, the amount of butter-fat yielded per head per day is above the average of the year from April to September inclusive; the amounts of solids not fat are over average from April to August inclusive; and the amounts of total solids yielded are average, or over average, from April to August inclusive.

From the foregoing results it is evident that the quantity of milk yielded per head is very much the greater during the grazing months of the year, but that the percentage composition of the milk is lower during that period of higher yield, and considerably higher during the months of more exclusively dry-food feeding. Nevertheless, owing to the much greater quantity of milk yielded during the grazing months, the actual quantity of constituents yielded per cow is greater during those months than during the months of higher percentage composition but lower yield of milk per head. It may be added that a careful consideration of the number of
newly-calved cows brought into the herd each month shows that the results as above stated were perfectly distinct, independently of any influence of the period of lactation of the different individuals of the herd.

The few results which have been brought forward in relation to milk-production are admittedly quite insufficient adequately to illustrate the influence of variation in the quantity and composition of the food on the quantity and composition of the milk yielded. Indeed, owing to the intrinsic difficulties of experimenting on such a subject, involving so many elements of variation, any results obtained have to be interpreted with much care and reservation. Nevertheless, it may be taken as clearly indicated that, within certain limits, high feeding, and especially high nitrogenous feeding, does increase both the yield and the richness of the milk. But it is evident that when high feeding is pushed beyond a comparatively limited range, the tendency is to increase the weight of the animal—that is, to favour the development of the individual, rather than to enhance the activity of the functions connected with the reproductive system.

This is, of course, a disadvantage when the object is to maintain the milk-yielding condition of the animal; but when a cow is to be fattened off it will be otherwise.

It has been stated that, early in the period of six years in which the Rothamsted results that have been quoted were obtained, the milk of the cows was derived according to the yield of milk of each individual cow; as it seemed unreasonable that an animal yielding, say, only 4 quarts per day, should receive, beside the home foods, as much cake as one yielding several times the quantity. The obvious inference is, that any excess of food beyond that required for sustenance and milk-production would tend to increase the weight of the animal, which, according to the circumstances, may or may not be desirable.

It may be observed that direct experiments at Rothamsted confirm the view, arrived at by common experience, that roots, and especially mangel, have a favourable effect on the flow of milk. Further, the Rothamsted experiments have shown that a higher percentage of butter-fat, of other solids, and of total solids, was obtained with mangel than with silage as the succulent food. The yield of milk was, however, in a much greater degree increased by grazing than by any other change in the food; and at Rothamsted the influence of roots comes next in order to that of grass, though far behind it, in this respect. But with grazing, as has been shown, the percentage composition of the milk is considerably reduced; though, owing to the greatly increased amount of soil-constituents removed in the milk when cows are grazing may nevertheless be greater per head per day than under any other conditions.

Lastly, it has been clearly illustrated how much very greater is the demand upon the food, especially for nitrogenous and for mineral constituents, in the production of milk than in that of fattening increase.

1 The evidence on this point taken by the Committee on Milk and Cereal Experiments in 1900 is somewhat conflicting. The report states that an impression commonly prevails that the quality of milk is more or less determined by the nature and composition of the food which the cow receives. One witness said that farmers who produce milk for sale feed differently from what they do if they are producing food for home consumption. Another stated that most of the statistics which go to show that food has no effect on milk fail, because the experiments are not carried far enough to counterbalance that peculiarity of the animal first to utilize the food for itself before utilising it for the milk. The law of the milk output of a cow being 100 milking cows expressed the opinion that improvement in the quality of milk can be effected by feeding, though not to any large extent. On the other hand, it was maintained that the fat percentage in the milk of a cow cannot be raised in any manner or method of feeding. It is possible that in the case of cows very poorly fed the addition of rich food would alter the composition of their milk, but if the cows are well-fed to begin with, this would not be so. The proprietor of a herd of 500 milking cows died last year, and that feeding affected the quality of milk from ordinarily well-kept animals. An experimenter found that the result of resorting to rather poor feeding was that the first effect was produced upon the weight of the cow and not upon the milk; the animal began to get thin, losing its weight, though there was not very much effect upon the quality of the milk.

MANURIAL VALUE OF FOOD CONSUMED IN THE PRODUCTION OF MILK

In any attempt to estimate the average value of the manure derived from the consumption of food for the production of milk, the difficulty arising from the very wide variation in the amount of milk yielded by different cows, or by the same cow at different periods of her lactation, is increased by the inadequate character of information concerning the difference in the amount of the food actually consumed by the animal coincidently with the production of such different amounts of milk. But although information is lacking for correlating, with numerical accuracy, the great difference in milk-yield of individual cows with the coincident differences in consumption to produce it, it may be considered as satisfactorily established that more food is consumed by a herd of cows to produce a fair yield of milk, of say 10 or 12 quarts per head per day, than by an equal live-weight of oxen fed to produce fattening increase. In the cases supposed it may, for practical purposes, be assumed that the cows would consume about one-fourth more food than the oxen. Accordingly, in the Rothamsted estimates of the value of the manure obtained on the consumption of food for the production of milk, it is assumed that one-fourth more will be consumed by the 100 lb live-weight of cows than by the same weight of oxen; but the estimates of the amount of the constituents of the food removed in the milk, or remaining for manure, are nevertheless reckoned per ton of each kind of food consumed, as in the case of those relating to feeding for the production of fattening increase. It may be added that the calculations of the amounts of the constituents in the milk are based on the same average composition of milk as is adopted in the construction of Table V. Thus the nitrogen is taken at 0·570 (3·625 nitrogenous substance)%, the phosphoric acid at 0·2175%, and the potash at 0·1875% in the milk.

Table VIII. shows in detail the estimate of the amount of nitrogen in one ton of each food, and in the milk produced from its consumption, on the assumption of an average yield of 10 quarts per head per day; also the amount remaining for manure, the amount of ammonia corresponding to the nitrogen, and the value of the ammonia at 4d. per lb. Similar particulars are also given in relation to the phosphoric acid and the potash consumed in the food, removed in the milk, and remaining for manure, &c.

This table will serve as a sufficient illustration of the mode of estimating the total or original value of the manure, derived from the consumption of the different foods, for the production of milk in the case of the milk; that is, assuming an average yield of a herd of 10 quarts per head per day.

In Table IX. are given the results of similar detailed calculations of the total or original manure-value (as in Table VIII. for 10 quarts), or on the alternative assumptions of a yield of 6, 8, 12 or 14 quarts per head per day. For comparison there is also given, in the first column, the estimate of the total or original manure-value when the foods are consumed for the production of fattening increase.

So much for the plan and results of the estimations of total or original manure-value of the different foods, that is, deducting only the constituents removed in the milk, and reckoning the remainder at the prices at which they can be purchased in artificial manures. With a view to direct application to practice, however, it is necessary to estimate the unexhausted manure-value of the different foods, or what may be called their compensation value, after they have been used for a series of years by the outgoing tenant and he has realized a certain portion of the manure-value in his increased crops. In the calculations for this purpose the rule is to deduct half of the original manure-value, after they have been used for a series of years by the outgoing tenant and he has realized a certain portion of the manure-value in his increased crops. In the calculations for this purpose the rule is to deduct half of the original manure-value, or...
## DAIRY

**Table VIII.---Estimates of the Total or Original Manure-Value of Cattle Foods after Consumption by Cows for the Production of Milk.**

Valuation on the assumption of an average production by a herd of 10 to 20 quarters of milk per head per day.

*one-fifth from year to year to the eighth year back.* The results of the estimates of compensation-value so made are given for the five yields of 6, 8, 10, 12 and 14 quarters of milk per head per day respectively in Lawes and Gilbert’s paper on the valuation of the manures obtained by the consumption of foods for the production of milk, which may be consulted for fuller details. It must, however, be borne in mind that when cows are fed in sheds or yards the manure is generally liable to greater losses than the case with fattening oxen. The manure of the cow contains much more water in proportion to solid matter than that of the ox. Water will, besides, frequently be employed for washing, and it may be that a good deal of the manure is washed into drains and lost. In the event, therefore, of a claim for compensation, the management and disposal of the manure requires the attention of the valuer. Indeed, the varying circumstances that will arise in practice must be carefully considered. Bearing these in mind, the estimates may be accepted as at any rate the best approximation to the truth that existing knowledge provides; and they should be found sufficient for the requirements of practical use. Obviously they will be more directly applicable in the case of cows feeding entirely on the foods enumerated in the list, and not depending largely on grass; but, even when the animals are partially grass-fed, the value of the manure derived from the additional dry food or roots may be estimated according to the scale given.

### CHEESE AND CHEESE-MAKING

For generations, perhaps for centuries, the question has been discussed as to why there should be so large a proportion of bad and inferior cheese and so small a proportion of really good cheese made in farmhouses throughout the land. That the result is not wholly due to skill and care or to the absence of these qualities on the part of the dairymaid may now be taken for granted. Instances might be quoted in which the most painstaking of dairymaids, in the cleanest of dairies, have failed to produce cheese of even second-rate quality and character, and yet others in which excellent cheese has been made under commonplace

Bestand as to skill and equipment, and with not much regard to cleanliness in the dairy. The explanation of what was so long a mystery has been found in the domain of fermentation. It is now known that when milk is left without free access to the milk, have ruined an in-calculable quantity of cheese—and of butter also—neither cheese nor butter of first-rate quality can be made without the aid of lactic acid bacilli. As an illustrative case, mention may be made of that of two most painstaking dairymaids who had tried in vain to make good cheese from the freshest of milk in the

...
mained, and heated to a temperature of 140° F., and returned to the curd, and thus the process was carried on till the desired temperature was reached. This mode of heating I considered very laborious and at the same time very unsatisfactory, as it is impossible to heat the curds properly by any method except the way by which the milk is heated with water or steam. The other general features of the method do not differ from our own very materially, with the exception that in the old method the curd was allowed to mature almost at will, whereas in the new method the operator regulates the maturing, or ripening, period. This is done by allowing the acid to develop properly before the addition of salt.

To determine when the curd is ready for salting, the hot-iron test is again resorted to; and when the curd will draw fine silky threads $\frac{1}{4}$ in. long, at the same time have a soft velvety feel, when pressed in the hand, the butter-fat will not separate with the whey from the curd. I generally advise using $1$ lb of salt to 50 lb of curd, more or less, according to the condition of the curd. After the curd is thoroughly ripened for two hours, or more, as the case may be, so as to allow the salt to be thoroughly dissolved before pressing.

In the pressing, care should be taken not to press too severely at first, as you are apt to lose some of the butter-fat, and when we notice that the butter-fat is deplored before the curd is properly softened, it is a sign that the pressure is too heavy at first. We advise three days’ pressing before cheese is taken to the curing-room. All cheese should have a bath in water at a temperature of 120° next morning after being made, to keep the curd intact, which stops the curd from contracting. The temperature of the curing-room should be kept as near 60° as possible at all seasons of the year, and I think if a good plan to ventilate while heating.

With regard to the hot-iron test for acidity, Mr F. J. Lloyd, in describing his investigations on behalf of the Bath and West of England Society, states that cheese-makers have long known that in both the manufacture and the ripening of cheese the acidity produced—known to the chemist as “lactic acid”—materially influences the results obtained, and that amongst other drawbacks to the test referred to is the uncertainty of the temperature of the iron itself. He gives an account, however, of a chemical method involving the use of a standard solution of an alkali (soda), and of a substance termed an “indicator” (phenolphthalein), which changes colour according to whether a solution is acid or alkaline. The apparatus used with these reagents is called the acimeter.

The two stages in the manufacture of a Cheddar cheese most difficult to determine empirically, are, (1) when the rennet is ready for adding, and (2) when to grind the curd. The introduction of the acimeter has done away with these difficulties; and though the use of this apparatus is not actually a condition essential to the manufacture of a good cheese, it is to many makers a necessity and to all an advantage. By its use the cheese-maker can determine the acidity of the whey, and so decide when to draw the latter off, and thus secure not only the proper development of acidity in the subsequent changes of cheese-making, but also materially diminish the time which the cheese takes to make.

Furthermore, it has been proved that the acidity of the whey which drains from the curd when in the cooler is a sufficiently accurate guide to the condition of the curd before grinding; and by securing uniformity in this acidity the maker will also ensure uniformity in the quality and ripening properties of the cheese. Speaking generally, the acidity of the whey from the press should never fall below 0.8° or rise above 1.2°, and the nearer it can be kept to 1.0° the better. Simultaneously, of course, strict attention must be paid to temperature, time and every other factor which can be accurately determined.

Analyses of large numbers of Cheddar cheeses manufactured in every month of the cheese-making season show the average composition of ripe specimens to be—water, 35.53%; fat, 31.31%; casein, 19.17; mineral matter or ash, 3.97. It has been maintained that in the ripening of Cheddar cheese fat is formed out of the curd, but a comparison of analyses of ripe cheeses with analyses of the curd from which the cheeses were made affords no evidence that this is the case.

The quantity of milk required to make 1 lb of Cheddar cheese may be learnt from Table X., which shows the results obtained at the cheese school of the Bath and West of England Society in the two seasons of 1899 and 1900. The cheese was sold at an average age of ten to twelve weeks. In 1899 a total of 21,250 gallons of milk yielded 20,537 lb of salable cheese, and in 1900, 31,828 gallons yielded 29,531 lb. In the two years together 53,385 gallons yielded 49,068 lb, which is equivalent to 1.05 gallon of milk to 1 lb of cheese. For practical purposes it may be

---

be taken that one gallon, or slightly over 10 lb., of milk, yields 1 lb. of pressed cheese. The prices obtained are added as a matter of interest.

Cheshire cheese is largely made in the county from which it takes its name, and in adjoining districts. It is extensively consumed in Manchester and Liverpool, and other parts of the densely populated county of Lancashire.

The following is a description of the making of Cheshire cheese:

The evening's milk is set apart until the morning, when the cream is skimmed off. The latter is poured into a pan which has been heated by being placed in the boiling water of a boiler. The new milk obtained early in the morning is poured into the vessels containing the previous evening's milk with the warmed cream, and the temperature of the mixture is brought to about 75°F. Into the vessel is introduced a piece of rennet, which has been kept in warm water since the preceding evening, and in which a little Spanish annatto (1 oz. is enough for a cheese of 60 lb.) is dissolved. (Marigold tea, boiled in milk, is occasionally used, and is often employed instead of rennet.) After the mixture has been stirred until the curd is well salted, the whey is set aside, the curd thickened, and the cheese removed to a vat, and salted, and then turned over and over until it is removed to a kettle, and placed in a press. The cheese is then placed in the cheese-vat, and the press is turned to the cheese-vat. Several processes occupy about six hours, and eight more are requisite for pressing the cheese, under a weight of 14 or 15 cwt. The cheese during that time should be turned in the vat, and also in the cover of it, to facilitate the extraction of every drop of whey. The pressure being continued, the cheese is at length taken from the vat as a firm and solid mass.

As a matter of fact, there are three different modes of cheese-making followed in Cheshire, known as the early ripening, the medium ripening and the late ripening processes. There is also a method which produces a cheese that is permeated with green mould, and is called this over to limited districts in the county. The early ripening method is generally followed in the spring of the year, until the middle or end of April; the medium process, from that time till late autumn, or until early in June, when the late process is well salted, and the end of September, changing again to the medium process as the season advances. The late ripening process is not found to be suitable for spring or late autumn make. There is a decided difference between these several methods of making. In the early ripening system a larger quantity of rennet is used, more acidity is developed, and less pressure employed than in the other processes. In the medium process, a moderate amount of acidity is developed, to cause the natural drainage of the whey from the curd when under press. In the late ripening system, on the other hand, the development of acidity is prevented as far as possible, and the whey is got out of the curd by breaking down finer, using more heat, and skewering when under press. In the Stilton Cheshire process a larger quantity of rennet is used, and less pressure is employed, than in the medium or late ripening systems.

It is hardly possible to enunciate any general rules for the making of Stilton cheese, which differs from Cheddar and Cheshire in that it is not subjected to pressure. Mr J. Marshall Dugdale, in 1890, made a visit of inspection to the chief Leicestershire dairies where this cheese is produced, but in his report he stated that every Stilton cheese-maker worked on his own lines, and that at no two dairies did he find the details all carried out in the same manner. There is a fair degree of uniformity up to the point when the curd is ladled into the straining-cloths, but at this stage, and in the treatment of the curd before salting, in the large number of varieties, and in different methods being in successful use. Most of the cheeses made from two curds, the highly acid curd from the morning's milk being mixed with the comparatively sweet curd from the evening's milk. Opinion varies widely as to the degree of tightening of the straining-cloths. No test for acidity appears to be used, the amount of acidity being judged by the taste, feel and smell of the curd. When the desired degree of acidity has developed, the curd is broken by hand to pieces the size of small walnuts, and salt is added at the rate of about 1 oz. per 4 lb. of dry curd, or to 1 oz. per 3 lb. of wet curd, care being taken not to get the curd pasty. If a maker has learnt how to rennet the milk properly, and how to secure the right amount of acidity at the time of hooping—that is, when the broken and salted curd is put into the wooden hoops which give the cheese its shape—he has acquired probably two of the most important details necessary to success. It was formerly the custom to add cream to the milk used for making Stilton cheese, but the general practice now is to employ new milk alone, which yields a product apparently as excellent and mellow as that from enriched milk.

As a cheese matures or becomes fit for consumption, not only is there produced the characteristic flavour peculiar to the type of cheese concerned, but with all varieties, independently of the quality of flavours developed, a profound physical transformation of the casein occurs. In the course of this change the firm plastic curd "breaks down"—that is, becomes plastic, whilst chemically the insoluble casein is converted into various soluble decomposition products. These ripening phenomena—the production of flavour and the breaking down of the casein (that is, the formation of proper texture)—is regarded as different phases of the same process. As subsequently shown, however, these changes are not necessarily so closely correlated. The theories formerly advanced as explanatory of the ripening changes in cheese were speculative rather than based upon experimental data, and it is only since 1866 that careful scientific studies of the problem have been made. Of the two existing theories, the one, which is essentially European, ascribes the ripening changes wholly to the action of living organisms—the bacteria present in the cheese. The other, which had its origin—

in the United States, asserts that there are digestive enzymes—that is, unorganized or soluble ferment—inherent in the milk itself that render the casein soluble. The supporters of the bacterial theory are ranged in two classes. The one, led by Dufaux, regards the breaking down of the casein as due to the action of liquefying bacteria (Tyrophilus forms). On the other hand, von Freudenreich has ascribed these changes to the lactic-acid type of bacteria, which develop so luxuriantly in hard cheese like Cheddar.

With regard to the American theory, and in view of the important practical results obtained by Babcock and Russell at the Wisconsin experiment station, the following account of their work is of interest, especially as the subject is of high practical importance. In 1897 they announced the discovery of an inherent enzyme in milk, which they named galactase, and which has the power of digesting the casein of milk, and producing chemical decomposition products similar to those that normally occur in ripened cheese. The theory has been advanced by them that this enzyme is an important factor in the ripening changes; and as in their experiments bacterial action was excluded by the use of anaesthetic agents, they conclude that, so far as the breaking down of the casein is concerned, bacteria are not essential to this process. In formulating a theory of cheese-ripening, they have further pointed out the necessity of considering the action of rennet extract as a factor concerned in the curing changes. They have shown that the addition of increased quantities of rennet extract materially hastens the rate of ripening, and that this is due to the pepsin which is present in all commercial rennet extracts. They find it easily possible to differentiate between the proteolytic action—that is, the decomposing of proteids—of pepsin and galactase, in that the first-named enzyme is incapable of producing decomposition products lower than the peptones precipitated by tannin. They have shown that the increased solubility—the ripening changes—of the casein in cheese made with rennet is attributable solely to the products peculiar to peptic digestion. The addition of rennet extract or pepsin to fresh milk does not produce this change, unless the acidity of the milk is allowed to develop to a point which experience has shown to be the best adapted to the making of Cheddar cheese. The rationale of the empirical process of ripening the milk before the addition of the rennet is thus explained. In studying the properties of galactase it was further found that this enzyme, as well as those present in rennet extract, is operative at very low temperatures, even below freezing-point. When cheese made in the normal manner was kept at temperatures ranging from 25° to 45° F. for periods averaging from eight to eighteen months, it was found that the texture of the product simulated that of a perfectly ripened cheese, but that such cheese developed a very mild flavour in comparison with the normally-cured product. Subsequent storage at somewhat higher temperatures gives to such cheese a flavour the intensity of which is determined by the duration of storage. This indicates that the breaking down of the casein and the production of the flavour peculiar to cheese are in a way independent of each other, and may be independently controlled—a point of great economic importance in commercial practice. Although it is generally believed that cheese ripened at low temperatures is apt to develop a more or less bitter flavour, the flavours in the cases described were found to be practically perfect. Under these conditions of curing, bacterial activity is inoperative, and these experiments are held to furnish an independent proof of the enzyme theory.

Not only are these investigations of interest from the scientific standpoint, as throwing light on the obscure processes of cheese-curing, but from a practical point of view they open up a new field for commercial exploitation. The inability to control the temperature in the ordinary factory curing-room results in serious losses, owing to the poor and uneven quality of the product, and the consumption of cheese has been greatly lessened thereby. These conditions may all be avoided by this low-temperature curing process, and it is not improbable that the cheese industry may undergo important changes in methods of treatment.

1 Experiment Station Record, xii. 9 (Washington, 1901).
good cream cheese is fairly firm but mellow, with a slightly acid yet very attractive flavour. It is the simplest of all cheese to make—cream poured into a perforated box lined with loose muslin practically makes itself into cheese in a few days’ time, and is usually ripe in a week.

In France the pressed varieties of cheese with hard rinds include Gruyère, Cantal, Roquefort and Port Salut. The first-named, a pale-yellow cheese full of holes of varying size, is made in Switzerland and in the Jura Mountains district in the east of France; whilst Cantal cheese, which is of lower quality, is a product of the midland districts and is made barrel-shaped. Roquefort cheese is made from the milk of ewes, which are kept chiefly as dairy animals in the department of Aveyron, and the cheese is cured in the natural mountain caves at the village of Roquefort. It is a small, rather soft, white cheese, abundantly veined with a greenish-blue mould and weighs between 4 and 5 lb. The Port Salut is quite a modern cheese, which originated in the abbey of that name in Mayenne; it is a thin, flat cheese of characteristic, and not unattractive odour and flavour. The best known of the soft unpressed cheeses are Brie, Camembert and Coulommiers, whilst Pont l’Évêque, Livarot and other varieties are also made. After being shaped in moulds of various forms, these cheeses are laid on straw mats to cure, and when fit to eat they possess about the same consistency as butter. The Neufchâtel, Gervais and Bondon cheeses are soft varieties intended to be eaten quite fresh, like cream cheese.

Of the varieties of cheese made in Switzerland, the best known is the Emmenther, which is about the size of a cart-wheel, and has a weight varying from 150 to 300 lb. It is full of small holes of almost uniform size and very regularly distributed. In colour and flavour it is the same as Gruyère. The Edam and Gouda are the common cheeses of Holland. The Edam is spherical in shape, weighs from 3 to 4 lb, and is usually dyed crimson on the outside. The Gouda is a flat cheese with convex edges and is of any weight up to 20 lb. Of the two, the Edam has the finer flavour. Limburger is the leading German cheese, whilst various other varieties are the Backstein and Munster; all are strong-smelling. Parmesan cheese is an Italian product, round and flat, about 5 in. thick, weighing from 60 to 80 lb and possessed of fine flavour. Gorgonzola cheese, so called from the Italian town of that name near Milan, is made in the Cheddar shape and weighs from 20 to 40 lb. When ripe it is permeated by a blue mould, and resembles in flavour, appearance and consistency a rich old Stilton.

For descriptions of all the named varieties of cheese, see Bulletin 105 of the Bureau of Animal Industry (U.S. Department of Agriculture, Washington), issued 27th of June 1908, compiled by C. F. Doane and H. L. Watson.

**Butter and Butter-Making**

As with cheese, so with butter, large quantities of the latter have been inferior not because the cream was poor in quality, but because the wrong kinds of bacteria had taken possession of the atmosphere in hundreds of dairies. The greatest if not the latest novelty in dairying in the last decade of the 19th century was the isolation of lactic acid bacilli, their cultivation in a suitable medium, and their employment in cream preparatory to churning. Used thus in butter-making, an excellent product results, provided cleanliness be scrupulously maintained. The culture repeats itself in the buttermilk, which in turn may be used again with marked success. Much fine butter, indeed, was made long before the bearing of bacteriological science upon the practice of dairying was recognized—made by using acid buttermilk from a previous churning.

In Denmark, which is, for its size, the greatest butter-producing country in the world, the most of the butter is made with the aid of “starters,” or artificial cultures which are employed in ripening the cream. Though the butter made by such cultures shows little if any superiority over a good sample made from cream ripened in the ordinary way—that is, by keeping the cream at a fairly high temperature until it is ready for churning, when it must be cooled—it is claimed that the use of these cultures enables the butter-makers of Denmark to secure a much greater uniformity in the quality of their produce than would be possible if they depended upon the ripening of the cream through the influence of bacteria taken up in the usual way from the air.

Butter-making is an altogether simpler process than cheese-making, but success demands strict attention to sound principles, the observance of thorough cleanliness in every stage of the work, and the intelligent use of the thermometer. The following rules for butter-making, issued by the Royal Agricultural Society sufficiently indicate the nature of the operation:—

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Expected Outcome</th>

</tr>
<tr>
<td>Rub thoroughly with salt</td>
<td>the butter will have the correct odour</td>
</tr>
<tr>
<td>Rinse with cold water</td>
<td>the butter will be properly washed</td>
</tr>
</tbody>
</table>

Always use a correct thermometer.

The cream, when in the churn, to be at a temperature of 56° to 58°F in summer and 60° to 62°F in winter. The churn should never be more than half full. Churn at number of revolutions suggested by the maker of churn. Churn at 40 to 45 revolutions per minute. Always churn slowly at first.

Vendilate the churn freely and frequently during churning, until no air rushes out when the vent is opened.

Stop churning immediately the butter comes. This can be ascertained by the sound; if in doubt, look.

The butter should now be like grains of mustard seed. Pour in a small quantity of cold water (1 pint of water to 2 quarts of cream) to drain the buttermilk, and then leave to stand. Draw off the buttermilk, giving plenty of time for draining. Use a straining-cloth placed over the hair-sieve, so as to prevent any loss, and wash the butter in the churn with plenty of cold water: then dry off the water, and repeat the process until the water comes off quite clear.

To brine butter, make a strong brine, 2 to 3 lb of salt to 1 gallon of water. Place straining-cloth over mouth of churn, pour in brine, and carefully drain off the brine in a thin stream, but do not leave for 10 to 15 minutes. Then lift the butter out of the churn into sieve, turn butter out on worker, leave it a few minutes to drain, and work gently till all superfluous moisture is pressed out.

To drysalt butter, place butter on worker, let it drain 10 to 15 minutes, then work gently till all the butter comes together. Place it on the scales and weigh; then weight salt, for light salting, oz.; for medium, 1 oz.; for heavy salting, oz. to the lb of butter. Roll butter out on worker and carefully sprinkle salt over the surface, a little at a time; roll up; rub well; then roll in salt is used.

Never touch the butter with your hands.

Well-made butter is firm and not greasy. It possesses a characteristic texture or “grain,” in virtue of which it cuts clean with a knife and breaks with a granular fracture, like that of cast-iron. Theoretically, butter should consist of lactic acid more than fat, but in practice this degree of perfection is never attained. Usually the fat ranges from 83 to 88%, whilst water is present to the extent of from 10 to 15%. There will also be from 0.2 to 0.8% of milk-sugar, and from 0.5 to 0.8% of casein. It is the casein which is the objectionable ingredient, and the presence of which is usually the cause of rancidity. In badly-washed or badly-worked butter, from which the buttermilk has not been properly removed, the proportion of casein or curd left in the product may be considerable, and such butter has only inferior keeping qualities. At the same time, the mistake may be made of overwashing or of overwashing the butter, thereby depriving it of the delicacy of flavour which is one of its chief attractions as an article of consumption if eaten fresh. The object of washing with brine is that the small quantity of salt thus introduced shall act as a preservative and develop the flavour. Streaky butter may be due either to curd left in by imperfect washing, or to an uneven distribution of the salt.

**Equipment of the Dairy**

The improved form of milking-pail shown in fig. 1 has rests or brackets, which the milker when seated on his stool places on his knees; he thus bears the weight on his thighs, and is entirely relieved of the strain involved in gripping the can between the knees. The milk sieve or strainer (fig. 2) is used to remove cow-hairs and any other mechanical impurity that may have fallen into the milk. A double straining surface is provided, the second being of very fine gauze placed vertically, so that the pressure of the milk does not force the dirt through; the strainer is easily washed. The cheese tub or vat receives

1 Market butter is sometimes deliberately over-weighted with water, and a fraudulent profit is obtained by selling this extra moisture at the price of butter.
the milk for cheese-making. The rectangular form shown in fig. 3 is a Cheshire cheese-vat, for steam. The inner vat is of tinned steel, and the outer is of iron and is fitted with pipes that the pressure is continuous; in the case of soft cheese the curd is merely placed in moulds (figs. 9 and 10) of the required shape, and then taken cut to ripen, no pressure being applied. The cheese-room is fitted with easily-turned shelves, on which newly-made "pressed" cheeses are laid to ripen.

In the butter dairy, when the centrifugal separator is not used, milk is "set" for cream-raising in the milk-pan (fig. 11), a shallow vessel of white porcelain, tinned steel or enamelled iron. The skimming-dish or skimmer (fig. 12), made of tin, is for collecting the cream from the surface of the milk, whence it is transferred to the cream-crock (fig. 13), in which vessel the cream remains from one to three days, till it is required for churning. Many different kinds of churns are in use, and vary much in size, shape and fittings; the one illustrated in fig. 14 is a very good type of diaphragm churn. The butter-scoop (fig. 15) is of wood and is sometimes perforated; it is used for taking the butter out of the churn. The butter-worker (fig. 16) is employed for consolidating newly-churned butter, pressing out superfluous water and mixing in salt. More extended use, however, is now being made of the "Delaïeuse" butter dryer, a centrifugal machine that rapidly extracts the moisture from the butter, and renders the

butter-worker unnecessary, whilst the butter produced has a better grain. Scotch hands (fig. 17), made of boxwood, are used for the lifting, moulding and pressing of butter.

In the centrifugal cream-separator the new milk is allowed to flow into a bowl, which is caused to rotate on its own axis several thousand times per minute. The heavier portion which makes up the watery part of the milk flies to the outer circumference of the bowl, whilst the lighter particles of butter-fat are forced to travel in an inner zone. By a simple mechanical arrangement the separated milk is forced out at one tube and the cream at another, and they are collected in distinct vessels. Separators are made of all sizes, from small machines dealing with 10 or 20 up to 100 gallons an hour, and worked by hand (fig. 18), or to large machines separating 120 to 440 gallons an hour, and worked by horse, steam or other power (fig. 19). Separation is found to be most effective at temperatures ranging in different machines from 80° to 98° F., though as high a temperature as 150° is sometimes employed. The most efficient separators remove nearly the whole of the butter-fat, the quantity of fat left in the separated milk falling in some cases to as low as 0·1. When cream is raised by the deep-setting method, from 0·2 to 0·4% of fat is left in the skim-milk; by the shallow-setting method from 0·3 to 0·5% of the fat is left behind.

As a rule, therefore, “separated” milk is much poorer in fat than ordinary “skim” milk left by the cream-raising method in deep or shallow vessels.

The first continuous working separator was the invention of Dr de Laval. The more recent invention by Baron von Bechtle- sheim of what are known as the Alfa discs, which are placed along the centre of the bowl of the separator, has much increased the separating capacity of the machines without adding to the power required. This has been great assistance to dairy farmers by lessening the cost of the manufacture of butter, and thus enabling a large additional number of factories to be established in different parts of the world, particularly in Ireland, where these disc machines are very extensively used.

The pasteurizer—so named after the French chemist Pasteur—affords a means whereby at the outset the milk is maintained at a temperature of 170° to 180° F. for a period of eight or ten minutes. The object of this is to destroy the tubercle bacillus, if it should happen to exist in the milk, whilst incidentally the bacilli associated with several other diseases communicable through the medium of milk would also be killed if they were present. Discordant results have been recorded by experimenters who have attempted to kill tubercle bacilli in milk by heating the latter in open vessels, thereby permitting the formation of a scum or “scalded layer” capable of protecting the tubercle bacilli, and enabling them to resist a higher temperature than otherwise would be fatal to them. At a temperature not much above 150° F. milk begins to acquire the cooked flavour which is objectionable to many palates, whilst its “body” is so modified as to lessen its suitability for creaming purposes. Three factors really enter into effective pasteurization of milk, namely (a) the temperature to which the milk is raised, (b) the length of time it is kept at that temperature, (c) the maintenance of a condition of mechanical agitation to prevent the formation of “scalded layer.”

Within limits, what a higher temperature will accomplish if maintained for a very short time may be effected by a lower temperature continued over a longer period. The investigation of the problem forms the subject of a paper in the 17th Annual Report of the Wisconsin Agricultural Experiment Station, 1900. The following are the results of the experiments:

1. An exposure of tuberculous milk in a tightly closed commercial pasteurizer for a period of ten minutes destroyed in every case the tubercle bacillus, as determined by the inoculation of such heated milk into susceptible animals like guinea-pigs.

2. Where milk is exposed under conditions that would enable a pellicle or membrane to form on the surface, the tubercle organism is able to resist the action of heat at 140°F. (60° C.) for considerably longer periods of time.
3. Efficient pasteurization can be more readily accomplished in a closed receptacle such as is most frequently used in the commercial treatment of milk, than where the milk is heated in open bottles or open vats.
4. It is recommended, in order thoroughly to pasteurize milk so as to destroy any tubercle bacilli which it may contain, without in any way injuring its creaming properties or consistency, to heat the same in closed pasteurizers for a period of not less than twenty minutes at 140°F.

Under these conditions one may be certain that disease bacteria such as the tubercle bacillus will be destroyed without the milk or cream being injured in any way. For over a year this new standard has been in constant use in the Wisconsin University Creamery, and the results, from a purely practical point of view, reported a year earlier by Farrington and Russell, have been abundantly confirmed.

Dairy engineers have solved the problem as to how large bodies of milk may be pasteurized, the difficulty of raising many hundreds or thousands of gallons of milk up to the required temperature, and maintaining it at that heat for a period of twenty minutes, having been successfully dealt with. The plant usually employed provides for the thorough filtration of the milk as it comes in from the farms, its rapid heating in a closed receiver and under mechanical agitation up to the desired temperature, its maintenance thereat for the requisite time, and finally its sudden reduction to the temperature of cold water through the agency of a refrigerator, to be next noticed.

Refrigerators are used for reducing the temperature of milk to that of cold water, whereby its keeping properties are enhanced. The milk flows down the outside of the metal refrigerator (fig. 20), which is corrugated in order to provide a larger cooling surface, whilst cold water circulates through the interior of the refrigerator. The conical vessel into which the milk is represented as flowing from the refrigerator in fig. 20 is absurdly called a "milk-churn," whereas milk-can is a much more appropriate name. For very large quantities of milk, such as flow from a pasteurizing plant, cylindrical refrigerators (fig. 21), made of tinned copper, are available; the cold water circulates inside, and the milk, flowing down the outside in a very thin sheet, is rapidly cooled from a temperature of 140°F or higher to 1°F above the temperature of the water.

The fat test for milk was originally devised by Dr S. M. Babcock, of the Wisconsin, U.S.A., experiment station. It combines the principle of centrifugal force with simple chemical action. Besides the machine itself and its graduated glass vessels, the only requirements are sulphuric acid of standard strength and warm water. The machines—often termed butyrometers—are commonly made to hold from two up to two dozen testers. After the tubes or testers have been charged, they are put in the apparatus, which is rapidly rotated as shown (fig. 22); in a few minutes the test is complete, and with properly graduated vessels the percentage of fat can be read off at a glance. The butyrometer is extremely useful, alike for measuring periodically the fat-producing capacity of individual cows in a herd, for rapidly ascertaining the percentage of fat in milk delivered to factories and paying for such milk on the basis of quality, and for determining the richness in fat of milk supplied for the urban milk trade. Any intelligent person can soon learn to

work the apparatus, but its efficiency is of course dependent upon the accuracy of the measuring vessels. To ensure this the board of agriculture have made arrangements with the National Physical Laboratory, Old Deer Park, Richmond, Surrey, to verify at a small fee the pipettes, measuring-glasses, and test-bottles used in connexion with the centrifugal butyrometer, which in recent years has been improved by Dr N. Gerber of Zürich.

**Dairy Factories**

In connexion with co-operative cheese-making the merit of having founded the first "cheesery" or cheese factory is generally credited to Jesse Williams, who lived near Rome, Oneida county, N.Y. The system, therefore, was of American origin. Williams was a skilled cheese-maker, and the produce of his dairy sold so freely, at prices over the average, that he increased his output of cheese by adding to his own supply of milk other quantities which he obtained from his neighbours. His example was so widely followed that by the year 1866 there had been established close upon 500 cheese factories in New York state alone. In 1870 two co-operative cheeseries were at work in England, one in the town of Derby and one at Longford in the same county. There are now thousands of factories in the United States and Canada, and also many "creameries," or butter factories, for the making of high-class butter.

The first creamery was that of Alanson Slaughter, and it was built near Wallkill, Orange county, N.Y., in 1861, or ten years later than the first cheese factory: it dealt daily with the milk of 375 cows. Cheeseries and creameries would almost certainly have become more numerous than they are in England but for the rapidly expanding urban trade in country milk. The development of each, indeed, has been contemporaneous since 1871, and they are found to work well in conjunction one with the other—that is to say, a factory is useful for converting surplus milk into cheese or butter when the milk trade is overstocked, whilst the trade affords a convenient avenue for the sale of milk whenever this may happen to be preferable to the making of cheese or butter. Extensive dealers in milk arrange for its conversion into cheese or butter, as the case may be, at such times as the milk market needs relief, and in this way a cheesery serves as a sort of economic safety-valve to the milk trade. The same cannot always be said of creameries, because the machine-skimmed milks of these establishments has been far too much used to the prejudice of the legitimate milk trade in urban districts. Be this as it may, the operations of cheeseries and creameries in conjunction with the milk trade have led to the diminution of home dairying. A rapidly increasing population has maintained, and probably increased, its consumption of milk, which has obviously diminished the farmhouse production of cheese, and also of butter. The foreign competitor has been less successful with cheese than with butter, for he is unable to produce an article qualified to compete with the best that is made in Great Britain. In the case of butter, on the other hand, the imported article, though not ever surpassing the best homemade, is on the average much better, especially as regards uniformity of quality. Colonial and foreign producers, however, send into the British markets as a rule only the best of their butter, as they are aware that their inferior grades would but injure the reputation their products have acquired.

There are no official statistics concerning dairy factories in Great Britain, and such figures relating to Ireland were issued for the first time in 1901. The number of dairy factories in Ireland in 1900 was returned at 461, comprising 335 in Munster, 93 in Ulster, 55 in Leinster and 29 in Connaught. Of the total number of factories, 495 received milk only, 9 milk and cream and 2 cream only. As to ownership, 279 were joint-stock concerns, 190 were maintained by co-operative farmers and 97 were proprietary. In the year ended 30th September 1900 these factories used up nearly 121 million gallons of milk, namely, 64 in Munster, 19 in Ulster, 7 in Leinster and 6 in Connaught. The number of centrifugal cream-separators in the factories was 985, of which 880 were worked by steam, 79 by water, 9 by horse-power and 8 by hand-power. The number of hands permanently employed was 3653, made up of 976 in Munster, 725 in Leinster, 278 in Ulster and 110 in Connaught. The year's output was returned at 401,490 cwt. of butter, 439 cwt. of cheese (made from whole milk) and 46,253 gallons of cream. In most cases the skim-milk is returned to the farmers. A return of the number of separators used in private establishments gave a total of 580, comprising 603 in Munster, 157 in Leinster, 36 in Ulster and 10 in Connaught. In factories and private establishments together as many as 1884 separators were thus accounted for. Much of the factory butter would be sent into the markets of Great Britain, though some would no doubt be retained for local consumption. A great improvement in the quality of Irish butter has recently been noticeable in the exhibits entered at the London dairy show.

**Adulteration of Dairy Produce**

The Sale of Food and Drugs Act 1889, which came into operation on the 1st of January 1900, contains several sections relating to the trade in dairy produce in the United Kingdom. Section 1 imposes penalties in the case of the importation of produce insufficiently marked, such as (a) margarine or margarine-cheese, except in passages conspicuously marked "Margarine" or "Margarine-cheese"; (b) adulterated or impoverished butter (other than margarine) or adulterated or impoverished milk or cream, except in packages or cans conspicuously marked with a name or description indicating that the butter or milk or cream has been so treated; (c) condensed separated or skimmed milk, except in tins or other receptacles which bear a label wherein the words "machine-skinned milk" or "skimmed milk" are printed in large and legible type. For the purposes of this section an article of food is deemed to be adulterated or impoverished if it has been mixed with any other substance, or if any part of it has been abstracted, so as in either case to affect injuriously its quality, substance, or nature; provided that an article of food shall not be deemed to be adulterated by reason only of the addition of any preservative or colouring matter of such a nature and in such quantity as not to render the article injurious to health. Section 7 provides that every occupier of a manufactory of margarine or margarine-cheese, and every wholesale dealer in such substances, shall keep a register showing the quantity of each article of margarine and margarine-cheese sold by him, and this register shall be open to the inspection of any officer of the board of agriculture. Any such officer shall have power to enter at all reasonable times any such manufactory, and to inspect any process of manufacture therein, and to take samples for analysis. Section 8 is of much practical importance, as it limits the quantity of butter-fat which may be contained in margarine; it states that it shall be unlawful to manufacture, sell, expose for sale or import any margarine the fat of which contains more than 10% of butter-fat, and every person who manufactures, sells, exposes for sale or imports any margarine which contains more than that percentage shall be guilty of an offence under the Margarine Act 1887. For the purposes of the act margarine-cheese is defined as "any substance, whether compound or otherwise, which is prepared in imitation of cheese, and which contains fat not derived from milk" whilst cheese is defined as "the substance usually known as cheese, containing no fat derived otherwise than from milk." The so-called "filled" cheese of American origin, in which the butter-fat of the milk is partially or wholly replaced by some other fat, would come under the head of "margarine-cheese." In making such cheese a cheap form of fat, usually of animal origin, but sometimes vegetable, is added to and incorporated with the skim-milk, and thus takes the place previously occupied by the genuine butter-fat. The act is regarded by some as defective in that it does not prohibit the artificial colouring of margarine to imitate butter.

In connexion with this act a departmental committee was appointed in 1900 to inquire and report as to what regulations, if any, may with advantage be made by the board of agriculture under section 4 of the Sale of Food and Drugs Act 1889, for

1 See also the article Adulteration.
determining what deficiency in any of the normal constituents of genuine milk or cream, or what addition of extraneous matter or proportion of water, in any sample of milk (including condensed milk) or cream, shall for the purposes of the Sale of Food and Drugs Acts 1875 to 1899, raise a presumption, until the contrary is proved, that the milk or cream is not genuine.

Much evidence of the highest interest to dairy-farmers was taken, and subsequently published as a Blue-Book (Cd. 484). The report of the committee (Cd. 491) included the following recommendations, which were signed by all the members excepting one:

I. That regulations under section 4 of the Food and Drugs Act 1899 be made by the board of agriculture with respect to the production and condensation of milk.

II. (a) That in the case of any milk (other than skimmed, separated or condensed milk) the total milk-solids in which were being dried at 100° C. do not amount to 12% a presumption shall be raised, until the contrary is proved, that the milk is deficient in the natural constituents of genuine milk.

(b) That any milk (other than skimmed, separated or condensed milk) the total milk-solids in which are less than 12%, and in which the amount of non-fat milk-solids is less than 8-5%, shall be deemed to be deficient in milk-fat, as to raise a presumption, until the contrary is proved, that it has been mixed with water, or that some portion of the normal content of milk-fat has been removed.

(c) In calculating the percentage amount of deficiency of fat, the analyst shall have regard to the above-named limit of 3-25% of milk-fat.

III. That the artificial thickening of cream by any addition of a dry substance shall raise a presumption that the cream is not genuine.

IV. That any skimmed or separated milk in which the total milk-solids are less than 9% shall be deemed to be so deficient in milk as to raise a presumption, until the contrary is proved, that it has been mixed with water.

V. That any condensed milk (other than that labelled "machine-skimmed milk" or "skimmed milk," in conformity with section 11 of the Food and Drugs Act 1899) in which either the amount of milk-fat is less than 10%, or the amount of non-fat milk-solids is less than 25%, shall be deemed to be so deficient in some of the normal constituents of milk as to raise a presumption, until the contrary is proved, that it is not genuine.

The committee further submitted the following expressions of opinion on points raised before them in evidence:

(a) That it is desirable to call the attention of those engaged in the administration of the Food and Drugs Acts to the necessity of adopting effective measures to prevent any addition of water, separated or condensed milk, or other extraneous matter, for the purpose of reducing the quality of genuine milk to any limits fixed by regulation of the board of agriculture.

(b) That it is desirable that steps should be taken with the view of identifying or "ear-marking" separated milk by the addition of some suitable and innocuous substance, and by the adoption of procedure similar to that provided by section 7 of the Food and Drugs Act 1899, in regard to margarine.

(c) That it is desirable that, so far as may be found practicable, the procedure adopted in collecting, forwarding, and retaining expenditure statements, samples of milk (including condensed milk) and cream under the Food and Drugs Acts should be uniform.

(d) That it is desirable that, so far as may be found practicable, the methods of analysis used in the examination of samples of condensed milk and cream taken under the Food and Drugs Acts should be uniform.

(e) That it is desirable in the case of condensed milk (other than that labelled "machine-skimmed milk" or "skimmed milk," in conformity with section 11 of the Food and Drugs Act 1899) that the label should state the amount of dilution required to make the proportion of milk-fat equal to that found in uncondensed milk containing not less than 3-25% of milk-fat.

(f) That it is desirable in the case of condensed whole milk to limit, and in the case of condensed machine-skimmed milk to exclude, the addition of sugar.

(g) That the official standardizing of the measuring vessels commonly used for the measurement of milk is desirable.

In the minority report, signed by Mr Geo. Barham, the most important clauses are the following:

(a) That in the case of any milk (other than skimmed, separated or condensed milk) the total milk-solids in which are less than 11-75%, and in which, during the months of July to February inclusive, the amount of milk-fat is less than 3%, and in the case of any milk which during the months of March to June inclusive shall fall below the above-named limit for total solids, and at the same time shall contain less than 2-75% of fat, it shall be deemed that such milk is so deficient in its normal constituent of fat as to raise a presumption, for the purposes of the Sale of Food and Drugs Acts 1875 to 1899, until the contrary is proved, that the milk is not genuine.

(b) That any milk (other than skimmed, separated or condensed milk) the total milk-solids in which are less than 11-75% and in which the amount of non-fat solids is less than 8-5%, shall be deemed to be so deficient in its normal constituents as to raise a presumption, for the purpose of the Sale of Food and Drugs Acts 1875 to 1899, until the contrary is proved, that the milk is not genuine.

Much controversy arose out of the publication of these reports, the opinion most freely expressed being that the standard recommended in the majority report was too high. The difficulty of the problem is illustrated by, for example, the diverse legal standards for milk that prevail in the United States, where the prescribed percentage of milk-fat of milk ranges from 2.5 to 8.5% in Rhode Island to 3.5 in Georgia and Michigan, and 3.7 (in the winter months) in Massachusetts, and the prescribed total solids range from 12 in several states (11.5 in Ohio during May and June) up to 13 in others. Standards are recognized in twenty-one of the states, but the remaining states have no laws prescribing standards for dairy products. That the public discussion of the reports of the committee was effective is shown by the following regulations which appeared in the London Gazette on the 6th of August 1901, and fixed the limit of fat at 3%:

The board of agriculture, in exercise of the powers conferred on them by section 4 of the Sale of Food and Drugs Act 1899, do hereby make the following regulations:

1. Where a sample of milk (not being milk sold as skimmed, or separated or condensed milk) contains less than 3% of milk-fat, it shall be presumed for the purposes of the Sale of Food and Drugs Acts 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the addition thereto of milk-fat, or the addition thereto of water.

2. Where a sample of milk (not being milk sold as skimmed, or separated or condensed milk) contains less than 8.5% of milk-solids other than milk-fat, it shall be presumed for the purposes of the Sale of Food and Drugs Acts 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the addition thereto of milk-solids other than milk-fat, or the addition thereto of water.

3. Where a sample of skimmed or separated milk (not being condensed milk) contains less than 9% of milk-solids, it shall be presumed, for the purposes of the Sale of Food and Drugs Acts 1875 to 1899, until the contrary is proved, that the milk is not genuine, by reason of the addition thereto of milk-solids other than milk-fat, or the addition thereto of water.

4. These regulations shall extend to Great Britain.

5. These regulations shall come into operation on the 1st of September 1901.

6. These regulations may be cited as the Sale of Milk Regulations 1901.

In July 1901 another departmental committee was appointed by the board of agriculture to inquire and report as to what regulations, if any, might with advantage be made under section 4 of the Sale of Food and Drugs Act 1899, for determining what deficiency in any of the normal constituents of butter, or what addition of extraneous matter, or proportion of water in any sample of butter should, for the purpose of the Sale of Food and Drugs Acts, raise a presumption, until the contrary is proved,
that the butter is not genuine. As bearing upon this point reference may be made to a report of the dairy division of the United States department of agriculture on experimental exports of butter, in the appendix to which are recorded the results of the analyses of many samples of butter of varied origin. First, as to American butters, 10 samples were analysed in Wisconsin, 17 in Iowa, 5 in Minnesota and 2 in Vermont, at the respective experiment stations of the states named. The amount of moisture throughout was low, and the quantity of fat correspondingly high. In no case was there more than 15% of water, and only 4 samples contained more than 14%. On the other hand, 11 samples had less than 10% the lowest being a pasteurized butter from Ames, Iowa, with only 6.72% of water. The average amount of water in the total 43 samples was 11.24%. The fat varies almost inversely as the water, small quantities of curd and ash having to be allowed for. The largest quantity of fat was 91.23% in the sample containing only 6.72% of water. The lowest proportion of fat was 80-18% whilst the average of all the samples shows 85.9% which is regarded as a good market standard. The curd varied from 0.55 to 1.9% with an average of 0.98. This small amount insures keeping qualities. Theoretically there should be no curd present, but this degree of perfection is never attained in practice. It was desired to have the butter contain about 2% of salt, but the quantity of ash in the 43 samples ranged from 0.83 to 4.79%, the average being 1.88. Analyses made at Washington of butters other than American showed a general average of 13-22% of water over 28 samples representing 14 countries. The lowest were 10-25% in a Canadian butter and 10.38% in an Australian sample. The highest was 10.1% in an Irish butter, which also contained the remarkably large quantity of 8.28% of salt. Three samples of Danish butter contained 12.65, 14.27 and 15.14% respectively of water. French and Italian unsalted butter included, the former 15.46 and the latter 14.41% of water, and yet appeared to be unusually dry. In 7 samples of Irish butters the percentages of water ranged from 11.48 to 19.1. Of the 28 foreign butters 15 were found to contain preservatives. All 5 samples from Australia, the 2 from France, the single ones from Italy, New Zealand, Argentina, and England, and 4 out of the 7 from Ireland, contained boric acid.

THE MILK TRADE

The term "milk trade" has come to signify the great traffic in country milk for the supply of dwellers in urban districts. Prior to 1860 this traffic was comparatively small or in its infancy. Thirty years earlier it could not have been brought into existence, for it is an outcome of the great network of railways which was spread over the face of the country in the latter half of the 19th century. It affords an instructive illustration of the process of commercial evolution which has been fostered by the vast increase of urban population within the period indicated. It is a tribute to the spirit of sanitary reform which—as an example in one special direction—has brought about the disestablishment of urban cow-sheds and the consequent demand for milk produced in the shires. London, in fact, is now being regularly supplied with fresh milk from places anywhere within 150 m., and the milk traffic on the railways, not only to London but to other great centres, is an important item. A factor in the development of the milk trade must no doubt be sought in the outbreak of cattle plague in 1865, for it was then that the dairymen of the metropolis were compelled to seek milk all over England, and the capillary refrigerating being invented soon after, the production of milk has remained ever since in the hands of dairymen living mainly at a distance from the towns supplied.

This great change in country dairying, involving the continuous export of enormous quantities of milk from the farms, has been accompanied by subsidiary changes in the management of dairies, and has necessitated the extensive purchase of feeding-stuffs for the production of milk, especially in winter-time. It is probable that, in this way, a gradual improvement of the soil on such farms has been effected, and the corn-growing soils of dista at counties are adding to the store of fertility of soils in the British Isles. Country roads, exposed to the wear and tear of a comparatively new traffic, are lively at morn and eve with the rattle of vehicles conveying fresh milk from the farms to the railway stations. Most of these changes were brought about within the limits of the last third of the 19th century.

In the case of London the daily supply of a perishable article such as milk, which must be delivered to the consumer within a few hours of its production, to a population of five millions, is an undertaking of very great magnitude, especially when it is considered that only a comparatively minute proportion of the supply is produced in the metropolis itself. To meet the demand of the London consumer some 5000 dairies proper exist, as well as a large number of businesses where milk is sold in conjunction with other commodities. It has been computed that some 12,000 traders are engaged in the business of milk-selling in the metropolis, and the number of persons employed in its distribution, &c., cannot be fewer than 25,000. The amount of capital involved is very great, and it may be mentioned that the paid-up capital of six of the principal distributing and retail dairy companies amounts to upwards of one million sterling.

The most significant feature in connection with the milk-supply of the metropolis at the beginning of the 20th century is the gradual extinction of the town "cowkeeper"—the retailer who produces the milk he sells. The facilities afforded by the railway companies, the favourable rates which have been secured for the transport of milk, and the more enlightened methods of its treatment after production, have made it possible for milk produced under more favourable conditions to be brought from considerable distances and delivered to the retailer at a price lower than that at which it has been possible to produce it in the metropolis itself. As a result, the number of milk cows in the county of London diminished from 10,000 in 1888 to 5144 in 1900, the latter, on an estimated production of 700 gallons per cow—the average production of stall-fed town cows—representing a yearly milk yield of 3,600,000 gallons. How small a proportion this is of the total supply will be gathered from the fact that the annual quantity of milk delivered in London on the Great Western line amounts to some 11,000,000 gallons, whilst the London & North-Western railway delivers 9,000,000, and the Midland railway at St. Pancras, 5,000,000. In addition to the 11,000,000 gallons of London stations about 1,000,000, making 6,000,000 in all. The South-Western railway brings upwards of 8,000,000 gallons to London, a quantity of 7,500,000 gallons is carried by the Great Northern railway, and the Great Eastern railway is responsible for 7,000,000. The London, Brighton & South Coast railway delivers 1,000,000 gallons, and the South-Eastern & Chatham and the London & Tilbury railways carry approximately 1,000,000 gallons between them. A large quantity of milk is also carried in by local lines from farms in the vicinity of London and delivered at the local stations, and a quantity is also brought by the Great Central railway. In addition to this, milk is taken into London by carts from farms in the neighbourhood of the metropolis. A computation of the total milk-supply of the metropolis reveals a quantity approximating to 66,000,000 gallons per annum, or rather more than a million gallons per week, which, taking 500 gallons as the average yearly production of the cows contributing to this supply, represents the yield of at least 20,000 cows. The growth of the supply of country milk to London may be judged from the figures given by Mr George Barham, chairman of the Express Dairy Co. Ltd., in an article on "The Milk Trade" contributed to Professor Sheldon's work on The Farm and Dairy. The quantities carried by the respective railways in 1888 are therein stated in gallons as:—Great Western, 9,000,000; London & North-Western, 7,000,000; Midland, 7,000,000; London & South-Western, 6,000,000; Great Northern, 3,000,000; Great Eastern, 3,000,000; the southern lines, 2,000,000. The increase, therefore, on these lines amounted to no less than 13,500,000 gallons per annum, or 36%. The diminished production in the metropolis itself amounted approximately only to 3,000,000 gallons, and it follows, therefore, that the consumption largely increased.
Previously to 1864 it was only possible to bring milk into London from short distances, but the introduction of the refrigerator has enabled milk to be brought from places as far removed from the metropolis as North Staffordshire, and it has even been received from Scotland. Practically the whole of the milk supplied to the metropolis is produced in England. Attempts have been made to introduce foreign milk, and in 1898 a company was formed to promote the sale of fresh milk from Normandy, but the enterprise did not succeed. The trade subsequently showed signs of reviving, owing probably to the increased cost of the home produced article, and during the winter season of 1900–1901 the largest quantity received into the kingdom in one week amounted to 10,000 gallons. Of recent years a large demand has sprung up for sterilized milk in bottles, and a considerable trade is also done in homogenized milk, which is a milk preparation approximating in its chemical composition to human milk.

Estimating the average yield of milk of each country cow at 500 gallons per annum, and assuming an average of 28 cows to each farm, as many as 4,500 farmers are engaged in supplying London with milk; allowing ten cows to each milkers, it needs 12 battalions of 1,000 men each for this work alone. Some 3,000 horses are required to convey the milk from the farms to the country railway stations. The chief sources of supply are in the counties of Derby, Stafford, Leicester, Northampton, Notts, Warwick, Bucks, Oxford, Gloucester, Berks, Wiltts, Hants, Dorset, Essex, and Cambridge. It is not entirely owing to the railways that London’s enormous supply of milk has been rendered possible, for the milk must still have been produced in the immediate neighbourhood of the metropolis had not the method of reducing the temperature of the product by means of the refrigerator been devised. There are probably 5700 horses engaged in the delivery of milk in London, and more people are employed in this work than in milking the cows. One of the great difficulties the London dairyman has to contend with, and a cause of frequent anxiety to him, is associated with the rise and fall of the thermometer, for a movement to the extent of ten degrees one way or the other may diminish or increase the supply in an inverse ratio to the demand. Thus, at periods of extreme cold, the cows shrink in their yield of milk, while from the same cause the Londoner is demanding more, in an extra cup of coffee, &c. Again, at periods of extreme heat, which has the same effect on the cow’s production as extreme cold, the customer also demands an increased quantity of milk. Ten degrees fall of temperature in the summer will result in a lessened demand and an enlarged supply—to such an extent, indeed, that a single firm has been known to have had returned by its carriers some 600 gallons in one day. In such cases the cream separator is capable of rendering invaluable assistance. To make cheese in London in large quantities and at uncertain intervals has been found to be impracticable, while to set for cream a great bulk of milk is almost equally so. But now a considerable portion of what would otherwise be lost is saved by passing the milk through separators, and churning the cream into butter.

Previously to the enormous development of the urban trade in country milk, dairy farms were in the main self-sustaining in the matter of manures and feeding-stuffs, and the cropping of arable land was governed by routine. To-day, on the contrary, many dairy farms are run at high pressure by the help of purchased materials,—corn, cake, and manure,—and the land is cropped regardless of routine and independent of courses. Such crops, moreover, are grown—white straw crops, green crops, root crops—as are deemed likely to be most needed at the time when they are ready. Green crops,—"soiling" crops, as they are termed in North America,—consisting largely of vetches or tame (held up by stails of oat plants grown amongst them), cabbages, and in some districts green maize, are used to supplement the falling grass-lands at the fall of the year, and root crops, especially mangel, are advantageously grown for the same purpose. For winter feeding the farm is made to yield what it will in the shape of meadow and other hay, and of course root crops of the several kinds. This provision is supplemented, by the purchase of, for example, brewers’ grains as a bulky food, and of olicake and corn of many sorts as concentrated food.

**British Output, Imports and Exports of Dairy Produce**

Whilst the quantity of imported butter and cheese consumed in the United Kingdom from year to year can be arrived at with a tolerable degree of accuracy, it is more difficult to form an estimate of the amounts of these articles annually produced at home. Various attempts have, however, from time to time been made by competent authorities to arrive approximately at the annual output of milk, butter and cheese in the United Kingdom, and the results are given by Messrs. W. Weddel & Co. in their annual *Dairy Produce Review*. Table XI. shows the estimates for each of the ten years 1890 to 1899, the numbers in the second column of "cows and heifers in milk or in calf" being identical with those officially recorded in the agricultural returns. In this estimating the quantity of milk, butter and cheese produced within the United Kingdom, the average milking life of a cow is taken to be four years, from which it follows that on the average one-fourth of the total herd has to be renewed every year by heifers with their first calf. This leaves 75% of the total herd giving milk throughout the year. Each cow of this 75% is estimated as yielding 49 cwt., or 531 gallons of milk annually. It is assumed that 15% of the total milk yield is used for the calf, 32% utilized for butter-

making, 30% for cheese-making, and the remaining 53% consumed in the household as fresh milk. A ton of milk is estimated to produce 2 lb of butter or 220 lb of cheese. A gallon of milk weighs 10.33 lb (457 lb). The probable effects of each season upon the production have been taken into consideration in making these estimates, and it will be noticed that owing to the terrible drought of 1893 a reduction of 6% is made from the average. Accepting these estimates with due reservation, it is seen that the annual production of milk varied in the decade to the extent of nearly a million tons, the exact difference between the maximum of 7,667,505 tons in 1894 and the minimum of 6,712,004 tons in 1893 being 955,501 tons.

The decennial averages are 7,906,874 tons of milk, 83,992 tons of butter, and 141,412 tons of cheese.

Table XII furnishes an estimate of the total consumption of butter in the United Kingdom in each of the years 1891 to 1900. Whilst the estimated home production did not vary greatly from year to year, the imports from colonial and foreign sources increased almost continuously. The ten years’ average indicates 37.6% home-made, 7.3% imported colonial, and 55.1% imported foreign. Butter. But whereas at the beginning of the decade the proportions were 45.4% home-made, 15.1% colonial, and 39.5% foreign, at the end of the percentages were 32.8, 14.7, and 52.5 respectively. It thus appears that whilst the United Kingdom was able in 1891 to furnish nearly half of its requirements (45.4%), by 1900 it was furnishing only a third (32.8%).

The rapid headway which colonial butter has made in British markets is shown by the fact that for the five years ended 30th of

June 1900 the import had grown from 12,949 tons to 37,534 tons per annum, or an increase of 24,585 tons. It is during the mid-winter months that the butter supplies from Australasia arrives on the British markets, while that from Canada begins to arrive in July, and virtually ceases in the following January. The bulk of the Canadian butter reaches British markets during August, September and October, the bulk of the Australasian in December, January and February.

It appears to be demonstrated by the experience of the last decade of the 19th century that the United Kingdom is quite unable to turn out sufficient dairy produce to supply its own population. The year ended 30th of June 1891 the total import of butter was 102,950 tons, and for the year ended 30th of June 1900 it was 170,700 tons, which shows an annual average increase in the decade of 6800 tons. This growth was unusually very rapid for colonial butter, its increase being attributable more to the deficient seasons in the colonies and foreign countries than to the bountiful seasons at home.

Twice in the decade the import of butter from colonial sources fell off slightly from the previous year, namely, in 1896 and 1898, while only once, in 1899, was there any decrease in the foreign supply, and this occurred in 1900. In 1896 the colonial supply fell off by 5000 tons, principally owing to drought in Australia, but from foreign countries this deficiency was more than made good, as the increased import from these sources exceeded 15,000 tons. In 1990 the position was reversed, for while the foreign import fell away to the extent of 8000 tons, from the supply from the colonies exceeded that of 1899 by 15,000 tons, thus leaving a gain in the quantity of imported butter of nearly 3000 tons in the year.

In the ten years 1891-1900, the import of colonial butter was augmented by 34,600 tons, and that of foreign by 33,600 tons, so that the increased import is fairly divided between colonial and foreign sources.

If, however, the last five years of the period be taken, it will be seen that the increase in the arrivals of colonial butter have far exceeded those from foreign countries. Between 1891 and 1900 the Australasian import increased from 10,110 tons to 11,100 tons. Of foreign countries, Denmark showed the greatest development in the supply of imported butter, which increased in the ten years by 28,678 tons. Next came Russia and Holland, with increases respectively of 20,678 tons and 7,858 tons annually; by 1900 it had fallen to 1850 tons. France, which in 1892 sent to the United Kingdom 29,000 tons, regularly declined, and in 1900 sent only 16,800. Among the countries sending the smaller quantities, Argentina, Belgium, and Norway are all gradually increasing their supplies; but their totals are comparatively insignificant, as they together contributed in 1900 only 6400 tons out of a total foreign supply of 272,312 tons. The United States was erratic in its supplies during the decade, and up to 1900 had not made butter specially for export to the United Kingdom, all the other foreign countries have done. Consequently it is only when supplies from elsewhere fail that American butter is sought for by British buyers. The large amount of salt in this butter, although suitable for the American palate, prevents its becoming popular in this country.

The sources whence the United Kingdom receives butter from abroad are sufficiently indicated in Table XIII, which shows the absolute quantities and the relative proportions sent by the chief contributory countries in each of the four years 1897 to 1900.

* Not shown separately in the Trade and Navigation Returns prior to 1900.

A special committee appointed by the council of the Royal Statistical Society commenced in 1901 an inquiry into the home production of milk and meat in the United Kingdom.
Canadian) has gained ground at the expense both of the home-made and of the foreign. Again, comparing 1891 with 1900, the import of cheese into the United Kingdom increased to the extent of only 24,500 tons, so that it shows no expansion comparable with that of butter, which increased by about 10,000 tons. Simultaneously the estimated home production diminished by 17,000 tons.

In imported colonial cheese Canada virtually has the field to itself, for the only other colonial cheese which finds its way into the United Kingdom is from New Zealand, but the amount of this kind is comparatively insignificant, having been in 1900 only 4,000 tons out of a total import of 128,600 tons. Australia, in several seasons since 1891, sent small quantities, but they are not worth quoting.

From foreign countries the decline in the export of cheese is mainly in the case of the United States, which shipped to British ports 10,000 tons less in 1890 than in 1891. France also loses its cheese trade in British markets, and is being supplanted by Belgium. In 1891 France shipped over 30,000 tons, but in 1900 contributed only 2600 tons. Belgium in 1891 supplied less than 1000 tons, but in 1900 contributed 2600 tons. The import trade in Dutch cheese remains almost stationary. In 1891 it amounted to 15,500 tons, in 1899 it was 15,600 tons, whilst in 1900, owing to exceptionally high prices, which stimulated the manufacture, it reached 17,000 tons.

Over 80% of the cheese imported into the United Kingdom is derived from North America, but the bulk of the trade belongs to Canada, which supplies nearly 60% of the entire import. The value of the cheese exported from Canada to the United Kingdom in the calendar year 1900 was close upon £3,000,000. As is shown in Table XV. below, Holland, Australasia and France participate in this trade, whilst amongst the other countries is Germany, Italy and Russia. The cheese sent from North America and Australasia is mostly of the substantial Cheddar type, whereas soft or 'fancy' cheese is the dominant feature of the French shipments. Thus, in the calendar year 1900 the average price of the cheese imported into the United Kingdom from France was 61s. per cwt., whilst the average value of the cheese from all other sources was 50s., per cwt., there being a difference of 11s. in favour of the "soft" cheese of France.

The imports of butter and margarine into the United Kingdom were not separately distinguished before 1888. Previous to that date they amounted, at five-year intervals, to the following aggregate quantities:

<table>
<thead>
<tr>
<th>Year</th>
<th>Cwt.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1870</td>
<td>1,159,210</td>
</tr>
<tr>
<td>1875</td>

</tbody>
</table>

The imports of butter and margarine, both separately and together, and also the imports of cheese in each year from 1886 to 1900 inclusive, are set out in Table XVI., the most significant feature of which is the rapid expansion it shows in the imports of butter. In the case of the years between 1887 and 1896, the quantity was doubled. On the other hand, the general tendency of the imports of margarine, which have been much more uniform than those of butter, has been in the direction of decline since 1892. It is necessary, however, to point out that there has been an increase in the number of margarine factories in the United Kingdom, and in the quantity of margarine manufactured in them, during the last few years. Taking the imports of butter and margarine together, the aggregate in 1899 and also in 1900 was practically three times as large as a quarter of a century earlier, in 1875. The imports of cheese have increased at a less rapid rate than those of butter, and the quantity imported in 1900, which was a maximum, fell considerably short of twice the quantity in 1875. In 1898, 1888, 1898, 1898 and 1898 the imports of cheese exceeded those of butter, but since the last-named year those of butter have always been the larger, and 1899 were fully a million cwt. more than the cheese imports. The cheapness of imported butter, which probably had the effect of checking the growth of the demand for cheese amongst the industrial classes.

The imports of condensed milk into the United Kingdom were separately distinguished before 1888, that year they amounted to 352,332 cwt. The quantities imported in subsequent years were the following:

<table>
<thead>
<tr>
<th>Year</th>
<th>Cwt.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1889</td>
<td>339,892</td>
</tr>
<tr>
<td>1890</td>
<td>359,597</td>
</tr>
<tr>
<td>1891</td>
<td>359,597</td>
</tr>
<tr>
<td>1892</td>
<td>359,597</td>
</tr>
<tr>
<td>1893</td>
<td>359,597</td>
</tr>
<tr>
<td>1894</td>
<td>359,597</td>
</tr>
<tr>
<td>1895</td>
<td>359,597</td>
</tr>
<tr>
<td>1896</td>
<td>359,597</td>
</tr>
<tr>
<td>1897</td>
<td>359,597</td>
</tr>
<tr>
<td>1898</td>
<td>359,597</td>
</tr>
</tbody>
</table>

The quantity thus increased continuously in each year after 1889, with the result that in 1900 the imports had grown to nearly three times the amount of those in 1889. Simultaneously, over the period 1890-1900 the annual value of the imports of condensed milk, valued in £70,489 to £1,405,033. Thus, while the imports of condensed milk trebled in quantity, they doubled in value. A fair proportion, however, is exported, as is shown in the following statement of exports of imported condensed milk for the four years 1897 to 1900:

<table>
<thead>
<tr>
<th>Year</th>
<th>Cwt.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1897</td>
<td>363,957</td>
</tr>
<tr>

</tbody>
</table>

Quantity. cwt. 143,932 113,596 141,984 164,602
Value £274,578 £256,552 £225,446 £309,460

There is also an export trade in condensed milk made in the United Kingdom. Thus, in 1892 the exports of home-made condensed milk amounted to 61,442 cwt., valued at £13,556. By 1896 the quantity had almost doubled, and reached 111,959 cwt., of the value of £23,831. In subsequent years the exports were:

<table>
<thead>

Quantity. cwt. 154,901 178,055 185,749 209,447
Value £302,748 £343,070 £353,818 £359,595

DAIRY
Milk and cream (fresh or preserved other than condensed) received no separate classification in the imports until 1894, in which year the quantity imported was 161,633 gallons, followed by 126,995 gallons in 1895, and 22,775 gallons in 1896. The quantities have since been returned by weight, 10,000 cwt. in 1897, 10,661 cwt. in 1898, 7,859 cwt. in 1899, and 15,638 cwt. in 1900. The values of these imports in the successive years 1894 to 1900 were £21,371, £19,991, £15,489, £12,357, £11,293, £16,058 and £25,837.

The total value of the imports of dairy produce of all kinds—butter, margarine, cheese, &c.—into the United Kingdom were, at five-year intervals between 1875 and 1890, the following:

<table>
<thead>
<tr>
<th>Year</th>
<th>Butter</th>
<th>Margarine</th>
<th>Cheese</th>
<th>Condensed Milk</th>

</tbody>
</table>

The values in each year of the closing decade of the 19th century are set forth in Table XVII., where the totals in the last column include small sums for margarine-cheese and, since 1893, for fresh milk and cream. The aggregate value more than doubled during the last quarter of the century. The earliest year for which the value was

The imports of butter are separately available is 1886, when it amounted to £8,141,438. Thirteen years later this sum had more than doubled, and it is an impressive fact that in the closing year of the century the United Kingdom should have expended on imported butter along a sum closely approaching to 1½ million pounds sterling, equivalent to about three-fourths of the total amount disbursed on imported wheat grain. 1

The imports of margarine—that is, of margarine specifically declared to be such—into the United Kingdom are derived almost entirely from Holland. Out of a total of 920,416 cwt. imported in 1900 Holland supplied 862,154 cwt., and out of £2,463,839 expended on imported margarine in the same year Holland received £2,295,174. To the imports in the year named Holland contributed 93.7%. France, 2.9%; Norway, 0.9; all other countries, 2.5%; so that Holland possesses almost a monopoly of this trade. The quantities of imported butter, margarine and cheese that are again exported from the United Kingdom are trivial when compared with the imports, as will be seen from the following quantities and values in the three years 1898 to 1900:

<table>
<thead>
<tr>
<th>Year</th>
<th>Butter</th>
<th>Margarine</th>
<th>Cheese</th>
<th>Total</th>

<td>£1,000</td>
<td>£1,000</td>
<td>£1,000</td>
<td>£1,000</td>
</tr>
</tbody>
</table>

There is also a very small export trade in butter and cheese made in the United Kingdom, but its insignificant character is evident from the subjoined details as to quantities and values for the years named:

<table>

</tbody>
</table>

Agricultural and Dairy Industry in the United States of America has been described in the official Year-Book by Major Henry E. Alvord, chief of the dairy division of the bureau of animal industry in the department of agriculture at Washington. The beginning of the 20th century found the industry upon an altogether higher level than seemed possible a few decades earlier. The milk cow herself, upon which

1 In 1901 the United Kingdom imported 3,702,810 cwt. of butter, valued at £19,297,005, both totals being the largest on record.

The whole business rests, however, upon the quality of the product. No machine can ever do the work as well as a trained hand. Machinery can only dispense with the laborious and inconvenient implements for use in the laborious duties of the dairy, have been replaced by perfected appliances, skilfully devised to accomplish their object and to lighten labour. Long rows of shining metal pans no longer adorn rural dooryards. The factory system of co-operative or concentrated manufacture has so far taken the place of home dairying that in entire states the cheese vat or press is as rare as the handloom, and in many counties it is as difficult to find a farm churn as a spinning-wheel. An illustration of the nature of the changes is afforded in the butter-making district of northern Vermont, at St Albans, the business centre of Franklin county. In 1880 the first creamery was built in this county; ten years later there were 15. Now a creamery company at St Albans has upwards of 50 skimming or separating stations distributed through Franklin and adjoining counties. These is carried the milk from more than 30,000 cows. Farmers who possess separators at home may deliver cream which, after being inspected and tested, is accepted and credited at its actual butter value, just as other raw material is sold to mills and factories. Cream is conveyed by rail and waggon to the central factory, where in one room from 10 to 12 tons of butter are made every working day—a single churning place for a whole county! The butter is all of standard quality, "extra creamery," and is sold on its reputation upon orders received in advance of its manufacture. The price is relatively higher than the average for the product of the same farms fifty years earlier. This is mainly due to better average quality and greater uniformity—two important advantages of the creamery system.

In one important detail dairy labour is the same as a century ago. Cows still have to be milked by hand. Although many attempts have been made, and patent after patent has been issued, no mechanical contrivance has yet proved a practical success as a substitute for the human hand in milking. Consequently, twice (or thrice) daily every day in the year, the dairy cows must be milked by manual labour. This is one of the main items of labour in dairying, and is a delicate and important duty. Assuming 10 cows per hour to a milker, which implies quick work, it requires the continuous service of an army of 300,000 men, working 10 or 12 hours a day throughout the year, to milk the cows kept in the United States.

The business of producing milk for urban consumption, with the accompanying agencies for transportation and distribution, has grown to immense proportions. In many places the milk trade is regulated and supervised by excellent municipal ordinances, which have done much to prevent adulteration and to improve the average quality of the supply. Quite as much is, however, being done by private enterprise through large milk companies, well organized and equipped, and establishments which make a specialty of serving milk and cream of fixed quality and exceptional purity. Such efforts to furnish "certified" and "guaranteed" milk, together with general competition for the best class of trade, are doing more to raise the standard of quality and improve the service than all the legal measures. The buildings and equipment of some of these modern dairies are beyond precedent. This branch of dairying is advancing fast, upon the safe basis of care, cleanliness and better sanitary conditions.

Cheese-making has been transferred bodily from the domain of domestic arts to that of manufactures. In the middle of the 19th century about 100,000,000 lb of cheese was made yearly in the United States, and all of it in farm dairies. At the beginning of the 20th century the annual production was about 300,000,000 lb, and 96 or 97% of this was made in factories. Of these there are nearly 3000, but they vary greatly in capacity, and some are very small. New York and Wisconsin possess a thousand each, but the former state makes nearly twice as much cheese as the latter, whilst the two together produce three-fourths of the entire output of the country. A change is taking place in the direction of bringing a number of factories previously independent into a
"combination" or under the same management." This tends to improve the quality and secure greater uniformity in the product, and often reduces the amount of waste. Milk and cheese, and the cheese made of the familiar standard type, copied after the English Cheddar, but new kinds and imitations of foreign varieties are increasing. The annual export of cheese from the United States ranges between 30,000,000 and 50,000,000 lb. The consumption per capita does not exceed 3 lb per annum, which is much less than in most European countries.

Butter differs from cheese in that it is still made more largely on farms in the United States than in creameries. Creamery butter controls all the large markets, but this represents little more than one-third of the entire business. Estimating the annual butter product of the entire country at 1,400,000,000 lb not much over 500,000,000 lb of this is made at the 7500 or 8000 creameries in operation. Iowa is the greatest butter-producing state, and the one in which the greater proportion is made on the factory plan. The total output of butter in this state is one-tenth of the entire output of the United States. The average quality of butter has materially improved since the introduction of the creamery system and the use of modern appliances. Nevertheless, a vast quantity of poor butter is made—enough to afford a large and profitable business in collecting it at country stores at much less than the city price, and then rendering or renovating it by patent processes. This renovated butter has been fraudulently sold to a considerable extent as the true creamery article, of which it is a fair imitation while fresh, and many states have passed laws for the identification of the product and to prevent buyers from being imposed upon. No butter is imported, and the quantity exported is insignificant, although there is beginning to be a foreign demand for American butter. The home consumption is estimated at the yearly rate of 20 lb per person, which, if correct, would indicate Americans to be the greatest butter-eating people in the world. The people of the United States also consume millions of pounds every year of butter substitutes and imitations, such as oleomargarine and butterine. Most of this is believed to be butter by those who use it, and the state dairy commissioners are busily employed in carrying out the laws intended to protect purchasers from these butter frauds.

The by-products of dairying have, within recent years, been put to economical uses, in an increasing degree. For every pound of butter made there are 15 to 20 lb of skim-milk and about 3 lb of butter-milk, and for every pound of cheese nearly 9 lb of whey. Up to 1885 or 1890 enormous quantities of skim-milk and butter-milk from the creameries and of whey from the cheese factories were entirely wasted. At farm dairies these by-products are generally used to advantage in feeding animals, but at the factories—especially at the seasons of greatest milk supply—this most desirable method of utilization is to a great extent impracticable. In many places new branches have been instituted for the making of sugar-of-milk and other commercial products from whey, and for the utilization of skim-milk in various ways. The albumin of the latter is extracted for use with food products and prepared as a substitute for eggs in baking, as the basis of an Italian paint, and as a substitute for glue in paper-sizing. It has also been proposed to solidify it to make buttons, combs, brush-backs, electrical insulators and similar articles.

No census of cows in the United States was taken until the year 1840, but they have been enumerated in each subsequent decennial census. From 23 to 27 cows to every 100 of the population were required. The majority of these were supplied with milk, butter and cheese, and also provided for the export of dairy products. The export trade, although it has fluctuated considerably, has never exceeded the production of 500,000 cows. At the close of the 19th century it was estimated that there was one milch cow per 4 to 5 persons, making the number of cows about 17,500,000. They are, however, very unevenly distributed, being largely concentrated in the great dairy states, Iowa leading with 1,500,000 cows, and being followed closely by New York. In the middle and eastern states the milk product goes very largely to the supply of the numerous towns and cities. In the central, west and north-west butter is the leading dairy product.

Table XVIII. shows approximately the quantity and value of the dairy products of the United States for a typical year, the grand total representing a value of $51,600,000. Adding to this the skim-milk, butter-milk and whey, at their proper feeding value, and the calves dropped yearly, the annual aggregate value of the produce of the dairy product of the United States is about $400,000,000. Accepting these estimates as conservative, they show that the commercial importance of the dairy industry of the United States is such as to justify all reasonable provisions for guarding its borders, with its friends at the high table, apart from the retainers and servants. In medieval halls there was generally a deep recessed bay window at one or at each end of the dais, supposed to be for retirement, or greater privacy than the open hall could afford. In France the word is understood as a canopy or hanging over a seat; probably the name was given from the fact that the seats of great men were then surmounted by such a feature. In ordinary use, the term means any raised platform in a room, for dignified occupancy.

DAISY (Fr. dais, estrade, Ital. predella), originally a part of the floor at the end of a medieval hall, raised a step above the rest of the building. On this the lord of the mansion dined with his friends at the high table, apart from the retainers and servants. In medieval halls there was generally a deep recessed bay window at one or at each end of the dais, supposed to be for retirement, or greater privacy than the open hall could afford. In France the word is understood as a canopy or hanging over a seat; probably the name was given from the fact that the seats of great men were then surmounted by such a feature. In ordinary use, the term means any raised platform in a room, for dignified occupancy.

DAISY (A.S. daesige, dæg's eye), the name applied to the plants constituting the genus Bellis, of the natural order Compositae. The genus contains ten species found in Europe and the Mediterranean region. The common daisy, B. perennis, is the only representative of the genus in the British Isles. It is a perennial, abundant everywhere in pastures and on banks in Europe, except in the most northerly regions, and in Asia Minor, and occurs as an introduced plant in North America. The stem of the daisy is short; the leaves, which are numerous and form a rosette, are slightly hairy, obovate-spathulate in shape, with rounded teeth on the margin in the upper part; and the root-stick is creeping, and of a brownish colour. The flowers are to be found from March to November, and occasionally in the winter months. The heads of flowers are solitary, the outer or ray-flares pink or white, the disk-flares bright yellow. The size and luxuriance of the plant are much affected by the nature of the soil in which it grows. The cultivated varieties, which are numerous, bear finely-coloured flowers, and make very effective borders for walks. What is known as the "hen-and-chicken" daisy has the main head surrounded by a brood of sometimes as many as ten or twelve small heads, formed in the axils of the scales of the involucre. The ray-flares curve inwards and "close" the flower-head in dull weather and towards evening.

Chaucer writes—
"The daisie, or els the eye of the dai,
That coulde be emprise, and 1500,000
One hundreth part of a penny ale";
and again—
"To see this floure agayst the sunne spred
dai. When it riseth early by the morrow,
That blissful sight softenth all my sorrow;"
and the flower is often alluded to with admiration by the other poets of nature. To the farmer, however, the daisy is a weed, and a most wasteful one, as it exhausts the soil and is not eaten by any kind of stock.

In French the daisy is termed la marguerite (μαργαρίτης, a pearl), and "herb margarit" is stated to be an old English appellation for it. In Scotland it is popularly called the gowan, and in Yorkshire it is the bairnwort, or flower beloved by children. The Christmas and Michaelmas daisies are species of Aster; the ox-eye daisy is Chrysanthemum Leucanthemum, a common weed in meadows and waste places. B. perennis flore-pleno, the
